I have published detailed accounts of the first 300 cases of simple extraction. (See *Arch. of Ophth.*, xvii, p. 91; xviii, p. 1; xix, p. 280.) The results were unusually satisfactory, viz.: good in 94⅓ per cent.; moderate in 4⅔ per cent.; failure in 1 per cent. I desire to mention that the unpromising cases were not related to the combined operation, but that the iridectomy was made only for special indications in which a manifest tendency to prolapse (on account of conditions lying in the eye, or created by the operation, too peripheric section, and the like) was the most frequent. Among the intercurrent 37 combined operations, *i. e.*, 11 per cent. of the whole number, there was no failure. Doubts have been expressed as to the reliability of such statistics, which means that the veracity or the sober judgment of the author is put in question. If we give the reader the data to verify our statistics, he may come forward and show our mistakes, or if he thinks our conclusions are too rosy, let him frankly utter his belief that we have been too enthusiastic. In my reports, as well as in those of several institutions, for instance, the New York Eye and Ear Infirmary, the Massachusetts Charitable Eye and Ear Infirmary, the Birmingham and Manchester Ophthalmic Hospitals, the cases are reported in tabular arrangement, with name and address of the patients. If in such publications no case is omitted, for what further evidence do the doubters ask?

We all know the fallacy of statistics unless the numbers are so great as to exclude the important element of chance. In presenting to you the results of the last 346 extractions, you will find that they have been less favorable than the first series of 327. Taking the two series together, we shall arrive nearer to the truth than by considering either alone.

A. UNCOMPLICATED CATARACTS, 301. LAST SERIES, 346 CASES.

Operated according to the simple method as above detailed.—Total, 257 cases: result good 227; moderate 28; failure 2; prolapse of iris 19. Secondary discission made in 163.

Simple extraction with removal of anterior capsule.—Total,19. Good 13; moderate 5; failure 1. Discission 5; prolapse of iris 3.

Combined extraction.—Total 23. Good 18; moderate 4; failure 1. Discission 16; incarceration of iris 1.

After preliminary iridectomy.—Total 2. Good 2; discission 1.

B. COMPLICATED CATARACTS, 45.

Simple extraction. Total 33. Good 23; moderate 4; failure 6. Included in these figures are two temporarily good eyes, healing and vision good. Detachment of retina in old highly myopic eyes, occurring months after the operation. Discission 6; prolapse of iris 1.

Combined extraction.—Total 10. Good 8; moderate 1; failure 1. Discission 5.

After preliminary iridectomy.—Total 2; moderate 2.

Suppressing the decimals we obtain from the above (241 good, 44 moderate results and 11 failures);

84 per cent. good results; 13 per cent. moderate results,and 3 per cent. of failure.

Out of the 37 extractions with iridectomy, 2 were failures. 37 is too small a number to draw comparisons from. If we add the rate of success in the first 300 cases of simple extraction to these here reported we obtain: 89 per cent. good; 9 per cent. moderate results and 2 per cent. of failure. This outcome is still very satisfactory, showing that in 683 successive cases of cataract (the complicated included) in which the combined operation was performed in only 10 per cent. no more than 2 per cent. of failure had to be recorded.

In conclusion, Mr. President, let me say that in cultivating the operations for cataract *I have endeavored in the first place to operate as safely as possible, and in the second place to obtain the greatest acuteness of vision compatible with the safest method of operation.*

Discussion.

Dr. Julian J. Chisolm, Baltimore:—We are so accustomed, and I think properly, to look to Dr. Knapp for advice, that we always note his suggestions and frequently act upon them. I think that the profession as well as the public who are interested factors in blindness, are to be congratulated on the decided changes, which, according to Dr. Knapp's remarks, he has made in the after treatment of cataract cases. He now allows his patients to get up and walk to their beds with the eyes unbandaged. That seems to be a marked change from his former practice. He also releases the eye not operated upon on the second day which is an immense change from the former eight days of bandaging. He also covers the eye much more lightly. This is also a great advantage. I think that the profession in later years has found that excessive restraint is not an essential part of a successful cataract treatment, and that we may allow our patients a great deal more latitude in movement than formerly. He says that it is essential to keep the patients at rest for twenty-four hours, but that after the first day has passed it is not so important, and that he then allows the use of the second eye for certain purposes. Dr. Knapp notes nineteen prolapses in his last series. Before leaving Baltimore, I had occasion to look over my records for the last year as regards the number of cases of prolapse. In my patients, the eye operated upon is closed by adhesive strap or bandage while on the table and the patient is then allowed to walk to his bed with the good eye, if he has one. This eye is never bandaged. While it may be the patient's pleasure to remain quiet, they have no occasion to go to bed unless they desire to. They sit up from the time of the operation and take their regular meals with a liberty and a liberality which,if not injurious, and my experience has so proved it, is a great luxury to the individual. I have found that I have not more than nine per cent. of prolapses. Dr. Knapp has had about seven per cent. As is well known, I have gone further than Dr. Knapp has yet attained. I do not see the necessity of excluding light from any of my patients. In over five hundred cases treated in the past five years I have allowed all these privileges of unrestraint to cataract patients and have had no occasion to regret it. The day will come when we shall find less need to restrict patients after cataract operations, and at the same time we shall not diminish the good results that all of us are so anxious to obtain. It was satisfactory to me in urging non-restraint practice, to find that Schweigger, who keeps his patients absolutely quiet, reports hernial troubles in seven per cent. He has, therefore, not gained much by his excessive care of keeping his patients on their back in bed. As to the removal of the hernia afterwards, I have been in the habit of excising those that I found. In the small prolapses, I have discarded excision and leave their disappearance to nature.

As to the dangers of extracting the anterior part of the capsule which I have done quite extensively of late, I find that whilst I secure a central pupil, posterior adhesions are not uncommon and that full dilatation under atropia does not constantly occur. I have however, found no detriment from this condition. The patients see well and continue to see well. I have not found that the adhesions led to any subsequent inflammatory trouble. I am still disposed to believe that if we can succeed in extracting the larger part of the anterior capsule by forceps, we avoid that second operation of cystotomy, which simple as it may seem, necessitates retaining the patients under treatment longer than they desire.

I am particularly gratified to find that Dr. Knapp has recently relinquished a great deal of the restraint which he formerly considered essential in the after treatment of cataract operations.

Dr. L. Webster Fox, Philadelphia:—It may not be inappropriate to bring to the notice of the members of the Association fine specimens of black cataract removed from three patients.

Case 1.—Female, age 50, gave the following history. In 1876 she gave birth to twins and immediately afterwards it was found that her vision grew dim, so that in six weeks the patient was not able to count fingers at arm's length. The cataract was removed May 11, 1890. The ordinary method was followed, with iridectomy, and the eye did well for three months, when a thickening of the capsule took place. The patient, during the period of her blindness, developed a high degree of convergent strabismus. On June 27, an operation was performed on both internal recti muscles and the eyes became straight.

By December the capsule in the left eye became so dense that vision fell to about 10-200. Having had no inflammatory reaction after the first operation, I obtained the consent of the patient to removed the lens of the right eye, which I did December 7. The operation was followed by satisfactory results. The following formula, cyl. + 6 ax. 180° ⊃ cyl. —3, ax. 90 gave 20-70, and with a sph. +3 extra front J. 8, was read. These glasses were worn until June 21, 1891, when another examination was made on account of a loss of the visual acuity. This formula was as follows: Sph.— 1. cyl. + 6 ax. 5°, two letters of 20-30 and with an extra front of sph. + 2 added J. 8 was read. The patient was examined in April of this year and no change was found in her vision. The thickened capsule still the same in the left eye. After the second operation erythropsia developed and continued for six months, when it gradually faded away and the eye has since remained normal to light sense.

Case 2.—Male, 61 years, was examined January 11, 1891, with the following history: The right eye was removed early in life on account of dropsy of the globe, by a physician in Boston. The left was always myopic to a high degree, but the patient was able to follow his occupation, book-binder, until April 13, 1880, when he suddenly lost his sight. He could not give a clear history of the trouble other than the sight grew bad and the cause was attributed to cataract. His family history was irrelevant. On January 25 I removed the cataract by the simple method; the only complication was a slight loss of vitreous which was highly fluid. The movement of the hand could be easily noticed after the operation. The eye did well until the night of the third day, when a sudden discharge of phosphene took place in the eye, which so alarmed the patient that he suddenly sprang from his bed; his nurse had difficulty in quieting him, an opiate was necessary to lessen pain. Early the next morning I found the eye ball very painful, high tension and vision gone. An intra-ocular hæmorrhage had taken place. Antiphlogystic treatment was resorted to, but the eye went from bad to worse and later the eye ball was removed to alleviate pain. Upon opening it I found complete detachment of the retina and a blood clot.

Case 3.—Female, age 61. Was not able to discern objects at a distance, high myopia, and during the last five years was practically blind. Upon examination I found double cataracts, both deeply pigmented but somewhat brownish in the centre. On June 21, 1891, I removed the lens (iridectomy) and the eye did well. Six weeks later an irido-cyclitis developed and the sight was lost. On November 8, 1890, I performed the simple method on the right eye and the result has been fairly satisfactory since. The patient has an acuity of vision equal to 20-100 with the best glasses. The specimens from the last patient are particularly interesting as they show the nucleus almost black while the cortical substance is translucent or almost white. These specimens have been preserved in a solution of boroglyceride. I shall have a chemist make an examination of these specimens and see whether any light can be thrown as to the causation of this pigmentation.

Dr. George E. Frothingham, Detroit:—This subject is one of great importance and I have been much interested in this paper. The statistics of Dr. Knapp show a very decided improvement over the statistics of former operations, but we all know that Dr. Knapp is a skilful operator, and in the reports of cases of simple extraction by many operators, the successes have been less numerous than in Dr. Knapp's cases. I remember looking over the report of Schweigger; there were 4.4 per cent. reported as absolute loss, and 19 per cent. of secondary cataract not reported as regards the results of the second operation. 76 per cent. only were reported as successful; and in the other reports, I have found that the percentage of successes was not better than in the operation of von Graefe. I have given some attention to this subject and have made a modified linear operation. I first extracted with the Beer knife. Soon afterward, the downward operation with the narrow knife was published. It was claimed to be as simple as couching, as perfect as the flap and as safe as the modified operation, and the suggestion was made that the operation might be done upwards. I published in 1874, an operation with the narrow knife very similar to, if not identical with, the simple operation. I entered the knife a little back of the clear margin of the cornea aiming to bring the apex within the clear margin of the cornea. I at first met with success, but I regret to say that I afterwards had to abandon it on account of the bad results which I had. I found that without iridectomy, there were the same difficulties in evacuating the lens as in the old flap operation. I found, however, the chief objection to be prolapse of the iris. This occurred in about ten per cent. of the cases and occurred as late as the fifth day, and some of the cases were very troublesome. I do not remember an eye that was absolutely lost.

Unless we can see these cases of prolapse early and replace them, we can do little. The eye which has been subjected to traumatism, bears illy another operation. As Dr. Knapp has declared, between the third and the tenth day we are debarred from operating on account of the increased danger. We must operate early or wait a long time and then inflammatory products have complicated so that I consider this one of the most serious complications with which we have to deal. I notice from Schweigger's report that he has 8.2 per cent. of prolapse and Dr. Knapp in 509 cases reports 42 cases of prolapse. We have therefore between eight and ten per cent. of prolapsed iris in this operation.

The question of sufficient vision is a very important one, and unless it can be shown that it gives a larger percentage of successful results we should be slow in adopting it.

In regard to the extraction of unripe cataracts by this method, my experience was that there was great difficulty in evacuating the lens thoroughly where the lens was immature and the cortex soft. We must have a lens that will slip through the iris, otherwise we cannot remove it except by traction instruments which cause bruising and stretching the iris, and result in complications such as iritis and plugging of the pupil with lens matter and inflammatory products.

My reason for iridectomy is that we can extract the lens through a smaller corneal incision. I believe that that will be generally admitted. It is a principle of general surgery that the larger the incision, the greater the traumatism and the less the likelihood of recovery. An incision of one-half the cornea is more dangerous and less likely to be kept in position than one not so large. Any of us who have made iridectomy with a small triangular knife know how impossible it is to displace the lips of the wound. The larger corneal incision endangers the continued coaptation of the wound long enough for primary union to take place. That is the reason for the iridectomy. I must admit that the traumatism of iridectomy is most grave. It remains to be shown that we increase the traumatism more by iridectomy than by an increased extent of corneal incision. Until that is shown, I think that the smaller corneal incision is based upon proper principles of surgery. It will take a vast time and much experience to establish the fact that an incision involving one-half the cornea is as safe as a smaller one. Four or five hundred or even a thousand cases are not enough to establish it.

Dr. Henry D. Noyes, New York:—I think that I am bound to say something in regard to the attempt to cure cataract by medication or anything else than extraction, for this matter is in the air. It exists in New York and has cropped out here. I may simply say that it is my firm belief after an observation of many years, that these cases of improvement in vision, which it is true do present themselves, are founded upon the fact that there is a healthier condition of the eye and of the patient; and furthermore, that a careful examination of the natural history, development and progress of cataract, will convince any one that there are various stages through which it passes, with corresponding changes in vision. At first cataract may be attended with opacities of the vitreous which may clear up, permit improved sight. What is still more important is, to discriminate the particular variety of cataract with which one has to deal. There are forms which may remain stationary for twenty years. There is a gentleman, a distinguished member of this Association to whom I said in 1884 that he was beginning to have cataract. I also told him that he would never lose his sight or the vision which as a surgeon he must possess. He still remains in the condition he was eight years ago. This assumption that galvanism, external applications, manipulations, massage, instillations of boro-glyceride, etc., can have any effect in improving the vision is founded upon insufficient evidence, and the mistake is extremely probable of supposing an improvement from natural causes to be the result of treatment.

In regard to operations for cataract, I do not propose to take up unnecessary time, but I have been learning from year to year and I have come to the conclusion that simple extraction is *a priori* the extraction that ought to be done. The question I think stands in this position, that those who do iridectomy ought to give a reason to justify it, because they mutilate the eye. I am free to admit that the visual result may be as good with as without iridectomy, but I am in a position to assert that the man who does iridectomy must give a satisfactory reason for the iridectomy.

In the second place, I am perfectly convinced that the essential thing in the extraction of cataract is not so much the precise position of the incision, although I believe that the limbus is the proper place, but it must be an ample incision involving close upon one-half of the cornea, I want one-tenth less than one-half. The diameter of the lens then makes no stretching of the corneal tissues. It is on this that the subsequent removal of soft matter depends and rapid healing of the wound may be predicated. I have grown a great deal more bold with the iris than formerly. I am not afraid to push it back with a sterilized spatula with great care, and remove soft matter. I recognize the value of manipulation of the lower lid. A little trick which is of value is to allow the aqueous humor to collect and then open the eye and allow the aqueous humor to remove the debris. I have discarded all attempts at irrigation of the anterior chamber, neither do I introduce a syringe; I occasionally employ external irrigation, injecting fluid against the wound. Cleansing of the anterior chamber is of the highest importance. The removal of the blood and softened lens substance which remains in the lips of the wound is best accomplished by a pledget of cotton moistened with a 1-5000 bi-chloride solution. With this the eye ball is swept off and the cotton can be passed over the edges of the wound and it brings substances out of the anterior chamber both by its direct action and by its capillary attraction. The opening in the capsule, I am not in the habit of making as Dr. Knapp does. I make it through the centre of the pupil and large, but I recognize the value of the cystome which he has demonstrated.

As to the dressing of the eye. I do not confine my patients with the rigor which formerly prevailed. I think that I have learned another thing and that is that the tendency to prolapse is largely produced by the pressure of the bandage. I think that favors prolapse. The attempt to tightly shut up the eye excites irritation and resistance on the part of the patient. As a dressing I apply a bandage more commonly of loose material with a small amount of cotton. This is often moistened with a solution of the bichloride to prevent the secretions from concreting and causing adhesions of the lids. This adhesion of the lids is one of the causes of irritation and causes the patient to make spontaneous efforts for his own relief. The prolapse of the iris is not so difficult of explanation. It depends upon three factors chiefly: First any rudeness in the operation itself giving rise to undue reaction, making the eye sensitive and preventing prompt adhesion of the wound. Second, and chiefly, the prolapse is produced by the efforts of the patient himself in his vigorous but unconscious efforts to keep the eye still. This may be brought about by the traction of the recti or the pressure of the orbicularis muscle. Thirdly, the prolapse may come from the accidental contact of the eye with the finger of the patient as he moves in bed. I think that the causes of prolapse may almost entirely be classed under the head of traumatism either from within or without. The reason that I still adhere to the bandage is because I consider the protection of the eye for the first two nights as an important safe-guard against accident. In the case of women where the bandage is troublesome on account of the hair, I sometimes use strips of india-rubber plaster with cotton beneath, but I am satisfied that undue pressure with the bandage is one of the favoring causes of prolapse. Furthermore, as to eserine or anything dropped into the eye, I have abandoned that. I am more apt to use atropia at the end of twenty-four hours, always at the end of forty-eight hours.

As to the capsule:—If there be any need for secondary capsulotomy, it is deferred until the second or third month, but I am perfectly ready to agree with Dr. Knapp in saying that capsulotomy is not always the simple operation which its ease of performance would indicate. I have seen it set up a most serious plastic irido-cyclitis, and early in my career I was made excessively cautious in doing this because of some sad experiences with irido-cyclitis and subsequent atrophy of the globe. Capsulotomy as described by Knapp is very beautifully conceived and admirably done at his hands, but there is another thing to be mentioned. We have inherited a fear of piercing the eye ball through the ciliary region but I think that in some respects we have grown too cautious about it. Within the last few years in occasional instances, where I had a thick capsule to deal with which one needle thrust through the cornea would not satisfactorily open, or which two needles passed through the cornea would not open, I have overcome the difficulty by passing a long double edged needle through the sclera and reached the pupillary area from behind, and although there is a little hæmorrhage, I have been surprised to find the reaction so insignificant. With the long lever thus afforded you can make a satisfactory opening which it is often impossible to do by any mode of procedure through the cornea. I have even passed one needle through the cornea and another long needle with double cutting edge through the sclera, in some difficult cases and attained success.

Dr. Eugene Smith, of Detroit:—Dr. Knapp has spoken of my forceps. I have brought with me several pairs that they might be seen. It is the forceps of Knapp with the exception of the dropping of the teeth. Finding it necessary to have the teeth project downward and backward to grasp the capsule, I had them made in that way. As that causes a little awkwardness in the introduction of the forceps, I have come to the conclusion that these teeth may be placed in a perfect plane. I have had an experience with thirty or forty cases and have yet to fail in extracting a piece of the capsule or in not so thoroughly rupturing the capsule as to prevent so far, every necessity for subsequent decision; I am fond of removing the anterior capsule.

My dressing is essentially the same as Dr. Knapp's.

It appears to me that those who advocate iridectomy hold that in order to get the lens out, you have to tilt it on its axis into the anterior chamber. Those of us who practice simple incision know that in the majority of cases this is not so, the iris slides up into the incision, the pupillary space corresponds with the incision in the cornea, the lens slides through and the iris drops back into the anterior chamber.

In regard to Schweigger's statistics I would say that they are different in his hospital and private practice. His percentage of successes is larger in private practice. Those who have visited his hospital know what some of his cases are.

I agree with Dr. Noyes in regard to what he has so well said in reference to our fear of the iris. I do not hesitate to return the iris forcibly, within reason, with a spatula and to repeat this two or three times if there is a tendency to prolapse. I do not hesitate to drop a solution of eserine, one grain to the ounce on the prolapsed iris. I have yet to see any untoward result follow these procedures. Of course I prefer not to do it. I have frequently followed the suggestion of Dr. Knapp, although I have not used the probe. I have taken the point of the spatula and rolled the periphery of the iris from beneath the limbus, and at the same time I try to remove any little fragments of cortical substance from the wound.

As far as the results from extraction of the capsule are concerned, I think that they compare favorably with those of other operations. If there is any little remnant present, I do not wash it out. I do not find a slight degree of simple iritis of any importance except occasioning a slightly prolonged retention of the patient. I escape it in a large proportion of the cases. As far as adhesions of the capsule are concerned, I have no doubt that in this operation we get them more frequently than we know anything about but the ordinary degrees of contraction and dilatation of the pupil under the natural influences of light is so small that in a large proportion of cases there is no teazing of the iris. If there be moderate adhesion, I do not think that it is as important as the danger of subsequent decision in many cases. That we may have to incise the posterior capsule, is well known.

Dr. X. C. Scott:—In regard to one of the cases reported as benefited under medicinal treatment, I would say that I saw the case a year ago. One eye was almost obscured by cataract and the other eye was very defective. The patient also informed me that there had been a gradual increase of the defective vision from the time it began to fail.

Dr. J. E. Minney, Topeka, Kan.:—I think that the simple operation requires more manual dexterity than where iridectomy is done. I have had one case in which prolapse occurred on the third or fourth day, and as Dr. Knapp has suggested, I allowed it to remain. The man's vision is excellent, but I am in constant dread of trouble.

I would take exception to one remark of Dr. Noyes in regard to iridectomy. When a man is called to a patient and does not prescribe any drug, he is expected to give a reason for not doing so. I do not think that the burden of proof rests upon those who do iridectomy, but upon those who do not do it.

Dr. B. Alexander Randall, Philadelphia:—If one must give a reason for continuing to do iridectomy, many of us will have to give as one reason, lack of that skill which comes from a large number of operations. Therefore I continue to do iridectomy.

In regard to the medicinal treatment of cataract, I have had some experience with my friend Dr. Risley, and have also myself followed a series of cases, not very large but distinct, where the swelling of the lens and the deterioration of vision was evident, and where I had myself seen the spicules encroach further upon the pupillary space. Yet I have seen such advancing conditions take on a retrograde change, the vitreous clear, the vision improve, and the lens, if not becoming more clear, certainly growing no more opaque nor swollen and productive of a fictitious myopia; and for a term of years this improvement has remained under treatment of a medicinal character.

Dr. Samuel D. Risley:—I think that the criticism of Dr. Erwin's paper grows out of the fact that he has not reported his cases fully. He has left the impression that the cataracts were cured, which I doubt very much if he intended to do. Some time ago I published a long series of carefully studied cases of incipiens, some of which I had followed for ten or twelve years, and last year read a second paper on the same subject before the Section. Dr. Noyes' remarks accord with my own experience. These cases must be placed in two classes. I have watched the opaque masses in the periphery for a long time and there has been no increase. We are all familiar with this large group. The claim which I made in my paper of last year was that the typical cataract was, in a large number of cases, not justly regarded as a senile change, but was the result of impaired nutrition of the eye, and that if the change were due to this cause, by improving the health of the eye by wisely directed treatment, we might retard the onward progress of the opacity of the lens. This experience has demonstrated the possibility of doing in a certain number of cases. Quite a large percentage of the cases reported went on to maturity, but many were retarded and still enjoy useful vision. There is one other point in favor of the treatment of incipient cataract, and that is, even if the onward progress is not arrested by the treatment, the eyeball is healthier and better able to withstand the trials of operation. I therefore feel that there is a field for study in this direction, and one which we should not altogether ignore. I wish to reiterate, however, that while I have again and again seen the anterior chamber grow deeper as the swelling of the lens subsided in incipient cataract, I have never witnessed the slightest diminution in any spicule of opacity in the lens under any method of treatment.

Dr. A. J. Erwin, Mansfield, O.:—You have doubtless observed that I do not suggest medication as a substitute for surgical interference in mature cataract. My distinct proposition is this, that where the existing vision is equal to the average vision that we get after extraction, it is better, all things considered, to save the lens with the vision as long as possible, for the reason that you not only save the patient the anxiety and distress of the operation, but also the risks that necessarily attend operations. Furthermore, there are many cases that could not be safely operated if ripe, and many others advance so slowly that the patient would be kept in comparative blindness for many years before an operation could be made. True, by medication the hundreds are not made by one fell swoop, as it were, like we do in extraction. Such treatment as I suggest takes time and work, but in our profession that should not be an objection. But the great obstacle to medication in cataract is the all-pervading surgery fad, and then it is so brilliant and so courageous to be a surgeon that one likes to forget all other therapeutic measures. I doubt, therefore, whether our more eminent oculists have either the time or inclination to give incipient cataract that long continued, attentive treatment as suggested in my paper, necessary to stop the advance of the disease. In answer to the criticism of an illustrious compeer from New York, whose book we read and whom we delight to follow, it is only necessary to say that he has, in his remarks, adopted the illogical method of thrusting an opinion upon this Society as a climax, after acknowledging that he had no experience in the medication of cataract. It is entirely gratuitous for any man to say that this or that therapeutic measure is worthless, unless he has carefully and persistently tried it. In the science of medicine the time is past when any man's opinion has either weight or value unless based upon observed facts. Hypothesis is nothing, opinion is nothing; facts alone count now.

I am glad my friend from Cleveland had the opportunity of examining Mr. Swineford, one of the cases in my report, five months later than my last examination. He has just informed me that the vision of his right eye was still good, but that he was nearly blind of the left, though not ripe, well, 2-200, as in my report, is probably about what he found. I do not pretend to say that these cases are permanently cured, or rather permanently checked, nor do I know that this treatment will permanently arrest the advance of cataract in any case; but I do believe that nearly all cases of incipient cataract can be arrested for at least a few years, and in many cases to the end of the lifetime of the individual, by these measures.

Dr. H. Knapp, of New York:—In regard to discarding the bandage and restraint, I think that Dr. Chisolm will agree with me that rest is one of the prime factors in obtaining primary union, so that it is merely a matter of compromise between the old roller bandage and other appliances for securing greater rest for the eye. If we could have secured greater rest with the roller bandage I should have kept it, but it was necessity that led me to the abandonment of this cumbersome dressing. In Heidelberg, I had little trouble in keeping the roller bandage on my patients. It seems that nationality has something to do with it. Put a roller bandage on the eyes of a restless patient in a New York summer, the next morning you will find it over the ears. This is worse than no bandage. In summer I use the simple bandage of which I have spoken. This gives me occasion to mention an appliance which has been used in Vienna for many years and advocated also in this country as a protection of the eye from traumatism. It consists in a mask of metal wire placed over the eye. The objection is that the wire moves with the roller and the stiff corner of the mask gets into the corner of the eye, doing more mischief than good.

So it is with the roller bandage—good in principle, unreliable in execution.

Another thing of which I want to speak is why I and many others, have abandoned iridectomy as a rule. Iridectomy is certainly advisable in a number of cases, preventing accidents that are worse than the enlargement of the pupil. I must say that I might have done more iridectomies than I have done—ten per cent. Dr. Chisolm says in advocacy of his isinglass plaster that he has no greater number of cases of prolapse, but in his last report there are thirty-three per cent. of iridectomies. The iris which is cut away, cannot prolapse. The number of intercurrent iridectomies in the simple operation must come into consideration.

Dr. J. J. Chisolm, Baltimore:—The report to which Dr. Knapp refers is a hospital report in which are included cases done by my assistants and they do iridectomies. The hospital report does not refer to my individual cases.

Dr. H. Knapp, of New York:—The danger in the simple operation comes from the prolapse of the iris, as it does in the combined operation and the danger from prolapse in the combined operation (the angular incarcerations) according to my experience is greater than the prolapse in the simple operation. Since I abandoned iridectomy, I have seen much less iritis, irido-cyclitis and other complications than before. Simple extraction is, I think, the safest operation and that is its principal claim. When I examine eyes on which extraction with iridectomy has been done by myself or others, I find incarceration of the iris in the corners not so rarely and incarceration of the capsule in the majority of cases. This leads to many reactive processes including sympathetic ophthalmia.

I never cut a prolapse, whether spontaneous or traumatic, unless I get it fresh. If there is blenorrhœa or another infective process, it is criminal to cut a prolapse, as this opens a door for the entrance of germs into the interior. These are only the immediate results of cutting the iris, but the later ones are just as deleterious. In the series of one thousand combined operations which I have reported, there were two or three cases of late suppuration following incarcerated iris. In some cases the incarceration was so small that it could not be seen. As a result of exposure there was purulent iritis and ophthalmitis in eyes that had been quiet for years. Such cases are well known. The danger from immediate prolapse of the iris is greater when the iris is cut than when it is left untouched. Some years ago while engaged in experiments with infective germs, I injected pyogenic cocci into the anterior chamber of rabbits. On examination of these eyes I found the cornea was full of germs, but the iris almost free from them. The iris protects the deeper parts. This fact may serve as a rule for guidance, that we should make an iridectomy only when the eye is still aseptic. Otherwise it is better to postpone the operation until all inflammatory irritation past.

The occurrence of prolapse is chiefly due to two things. The one is *traumatism.* In fifty per cent. of the cases there is a direct history of hurt or blood in the anterior chamber to indicate that the part had been injured. The second cause is a *peripheric section.* The introduction of excision of the iris was not the result of scientific thinking. Iridectomy was made because its originators could not help it. A large peripheric incision without iridectomy is impossible. This is not so when the section is placed in the limbus. As we cannot always be accurate, let us rather encroach upon the cornea than on the sclerotic. On the whole the subject is certainly one that still requires careful study and prolonged experience.

DOUBLE CONGENITAL DISLOCATION OF THE LENS.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY GEORGE FRIEBIS, M.D.,
OF PHILADELPHIA.

On Jan. 3, of this year, the Rev. Dr. B. of Philadelphia, brought his son Walter, now 7 years of age, to me desiring that something be done to improve his sight; stating that for some time past both he and the teacher had noticed that the boy had great difficulty in clearly defining objects, which were easily distinguished by other pupils of his class, at a reasonable distance from him, nor could he well define small letters at the usual reading distance. The examination revealed the rare condition known as congenital dislocation of the lenses; and in this instance the dislocation was symmetrical. I have the honor to show you an excellent drawing, made by Dr. J. Madison Taylor, of Philadelphia, illustrating the conditions. The lens in each eye was tilted upward, slightly backward and inward. The iris was responsive to light stimulation and only on close scrutiny could a slight tremulousness of the same, in the inferior, outer quadrant be detected. The fundus viewed by both the direct and indirect methods showed the curious phenomenon of aphakia with myopic refraction in both eyes. The lower periphery of the upward dislocated lens appeared as an irregularly marked black line. The fibres of the zone of Zinn, described by some observers upon the subject, as clearly discernible in the aphakial interspace, were absent in this case. Owing to the child's unsteadiness it was impossible to measure with accuracy the degree of refraction either of the lens or aphakial portion of the eye. I confess to have been slightly puzzled by the appearance of the lens, viewed by oblique illumination, deeming it at first glance, because of the strong grayish reflex of the lens, though entirely transparent by other methods of examination, a form of congenital cataract. The vitreous body and fundus were normal; the tension likewise. The test for vision in the R. E. = 15-70, L. E. 15-50 imperfectly; a manifest refraction at this time, which was rather hurriedly performed, gave a negative result. Upon a subsequent occasion, the pupils being dilated by atropine, I thoroughly tested his vision with different combinations, sphericals, cylinders and sphero-cylinders + and — which would be too wearisome to enumerate; I found the following formula gave the best results. R. E. S. —1 = cyl. —1 ax. 180 = 15-70 clearly, but in a moment he would again lose certain letters in the line. L. E. S. —1 = 15-50 perfectly but as in the R. E. he could not hold the line satisfactorily. A few weeks later on, I again tested his refraction without mydriatic or glasses. At this time vision for distance in the R. E. = 15-70, L. E. 15-50 imperfectly, these tests proving conclusively that the child was also amblyopic; a usual concomitant of congenital dislocation. Vision for reading was not improved by glasses in the slightest degree. In fact vision for small letters at about 8 inches was slightly better without glasses and he defined letters Snellen 1 at 8 to 10 inches fairly well, but had to search for them, this showing an amplitude of about 2 inches in each eye and that accommodation was not entirely abolished. Glasses were not prescribed. The field was tested and found to be normal; the color sense was unimpaired. Diplopia usually present and demonstrable in many cases of this character could not on account of the youth of the patient and some mental obtuseness be established.

In passing I would state, that Dr. Chas. S. Turnbull also saw this little patient with me but by no method of examination could we detect any other structural changes than those already mentioned. Both parents are healthy and have a family of nine children, all of whom have excellent vision. As some observers hold that congenital dislocation is largely due to heredity and that consanguinity often plays an important part in its causation, I closely questioned the father, a very intelligent man, as to his family history. I could not obtain a satisfactory answer confirmatory of his theory, but he stated that he had no definite knowledge of any hereditary tendencies in his wife's family. The late Dr. Wm. S. Little of Philadelphia, reported at the 19th meeting of the A. O. Society two cases of congenital dislocations of the lens, one was non-symmetrical and the other symmetrical. The latter case occurring in the practice of Dr. Turnbull, by whose courtesy I am enabled to show you an additional cut representing a double inward dislocation. Although this cut was shown at the meeting of the American Ophthalmological Society in 1883, yet I deemed it of sufficient interest, by way of contrast with my own case, to bring it to the attention of this meeting. Both patients were likewise markedly amblyopic and in each instance refraction of the existing ametropia gave a useful degree of vision. In Dr. Turnbull's case the lenses were so far dislocated as to make the eyes almost aphakial, but by the use of cataract glasses useful vision was obtained. Dr. Turnbull's patient gave no history of malformations in any of the members of his family or near relatives, but had himself a highly vaulted roof of mouth. Dr. Little's patient said that he had a cousin similarly affected and that repeat this two or three times if there is a tendency to prolapse. I do not hesitate to drop a solution of eserine, one grain to the ounce on the prolapsed iris. I have yet to see any untoward result follow these procedures. Of course I prefer not to do it. I have frequently followed the suggestion of Dr. Knapp, although I have not used the probe. I have taken the point of the spatula and rolled the periphery of the iris from beneath the limbus, and at the same time I try to remove any little fragments of cortical substance from the wound.

As far as the results from extraction of the capsule are concerned, I think that they compare favorably with those of other operations. If there is any little remnant present, I do not wash it out. I do not find a slight degree of simple iritis of any importance except occasioning a slightly prolonged retention of the patient. I escape it in a large proportion of the cases. As far as adhesions of the capsule are concerned, I have no doubt that in this operation we get them more frequently than we know anything about but the ordinary degrees of contraction and dilatation of the pupil under the natural influences of light is so small that in a large proportion of cases there is no teazing of the iris. If there be moderate adhesion, I do not think that it is as important as the danger of subsequent decision in many cases. That we may have to incise the posterior capsule, is well known.

Dr. X. C. Scott:—In regard to one of the cases reported as benefited under medicinal treatment, I would say that I saw the case a year ago. One eye was almost obscured by cataract and the other eye was very defective. The patient also informed me that there had been a gradual increase of the defective vision from the time it began to fail.

Dr. J. E. Minney, Topeka, Kan.:—I think that the simple operation requires more manual dexterity than where iridectomy is done. I have had one case in which prolapse occurred on the third or fourth day, and as Dr. Knapp has suggested, I allowed it to remain. The man's vision is excellent, but I am in constant dread of trouble.

I would take exception to one remark of Dr. Noyes in regard to iridectomy. When a man is called to a patient and does not prescribe any drug, he is expected to give a reason for not doing so. I do not think that the burden of proof rests upon those who do iridectomy, but upon those who do not do it.

Dr. B. Alexander Randall, Philadelphia:—If one must give a reason for continuing to do iridectomy, many of us will have to give as one reason, lack of that skill which comes from a large number of operations. Therefore I continue to do iridectomy.

In regard to the medicinal treatment of cataract, I have had some experience with my friend Dr. Risley, and have also myself followed a series of cases, not very large but distinct, where the swelling of the lens and the deterioration of vision was evident, and where I had myself seen the spicules encroach further upon the pupillary space. Yet I have seen such advancing conditions take on a retrograde change, the vitreous clear, the vision improve, and the lens, if not becoming more clear, certainly growing no more opaque nor swollen and productive of a fictitious myopia; and for a term of years this improvement has remained under treatment of a medicinal character.

Dr. Samuel D. Risley:—I think that the criticism of Dr. Erwin's paper grows out of the fact that he has not reported his cases fully. He has left the impression that the cataracts were cured, which I doubt very much if he intended to do. Some time ago I published a long series of carefully studied cases of incipiens, some of which I had followed for ten or twelve years, and last year read a second paper on the same subject before the Section. Dr. Noyes' remarks accord with my own experience. These cases must be placed in two classes. I have watched the opaque masses in the periphery for a long time and there has been no increase. We are all familiar with this large group. The claim which I made in my paper of last year was that the typical cataract was, in a large number of cases, not justly regarded as a senile change, but was the result of impaired nutrition of the eye, and that if the change were due to this cause, by improving the health of the eye by wisely directed treatment, we might retard the onward progress of the opacity of the lens. This experience has demonstrated the possibility of doing in a certain number of cases. Quite a large percentage of the cases reported went on to maturity, but many were retarded and still enjoy useful vision. There is one other point in favor of the treatment of incipient cataract, and that is, even if the onward progress is not arrested by the treatment, the eyeball is healthier and better able to withstand the trials of operation. I therefore feel that there is a field for study in this direction, and one which we should not altogether ignore. I wish to reiterate, however, that while I have again and again seen the anterior chamber grow deeper as the swelling of the lens subsided in incipient cataract, I have never witnessed the slightest diminution in any spicule of opacity in the lens under any method of treatment.

Dr. A. J. Erwin, Mansfield, O.:—You have doubtless observed that I do not suggest medication as a substitute for surgical interference in mature cataract. My distinct proposition is this, that where the existing vision is equal to the average vision that we get after extraction, it is better, all things considered, to save the lens with the vision as long as possible, for the reason that you not only save the patient the anxiety and distress of the operation, but also the risks that necessarily attend operations. Furthermore, there are many cases that could not be safely operated if ripe, and many others advance so slowly that the patient would be kept in comparative blindness for many years before an operation could be made. True, by medication the hundreds are not made by one fell swoop, as it were, like we do in extraction. Such treatment as I suggest takes time and work, but in our profession that should not be an objection. But the great obstacle to medication in cataract is the all-pervading surgery fad, and then it is so brilliant and so courageous to be a surgeon that one likes to forget all other therapeutic measures. I doubt, therefore, whether our more eminent oculists have either the time or inclination to give incipient cataract that long continued, attentive treatment as suggested in my paper, necessary to stop the advance of the disease. In answer to the criticism of an illustrious compeer from New York, whose book we read and whom we delight to follow, it is only necessary to say that he has, in his remarks, adopted the illogical method of thrusting an opinion upon this Society as a climax, after acknowledging that he had no experience in the medication of cataract. It is entirely gratuitous for any man to say that this or that therapeutic measure is worthless, unless he has carefully and persistently tried it. In the science of medicine the time is past when any man's opinion has either weight or value unless based upon observed facts. Hypothesis is nothing, opinion is nothing; facts alone count now.

I am glad my friend from Cleveland had the opportunity of examining Mr. Swineford, one of the cases in my report, five months later than my last examination. He has just informed me that the vision of his right eye was still good, but that he was nearly blind of the left, though not ripe, well, 2-200, as in my report, is probably about what he found. I do not pretend to say that these cases are permanently cured, or rather permanently checked, nor do I know that this treatment will permanently arrest the advance of cataract in any case; but I do believe that nearly all cases of incipient cataract can be arrested for at least a few years, and in many cases to the end of the lifetime of the individual, by these measures.

Dr. H. Knapp, of New York:—In regard to discarding the bandage and restraint, I think that Dr. Chisolm will agree with me that rest is one of the prime factors in obtaining primary union, so that it is merely a matter of compromise between the old roller bandage and other appliances for securing greater rest for the eye. If we could have secured greater rest with the roller bandage I should have kept it, but it was necessity that led me to the abandonment of this cumbersome dressing. In Heidelberg, I had little trouble in keeping the roller bandage on my patients. It seems that nationality has something to do with it. Put a roller bandage on the eyes of a restless patient in a New York summer, the next morning you will find it over the ears. This is worse than no bandage. In summer I use the simple bandage of which I have spoken. This gives me occasion to mention an appliance which has been used in Vienna for many years and advocated also in this country as a protection of the eye from traumatism. It consists in a mask of metal wire placed over the eye. The objection is that the wire moves with the roller and the stiff corner of the mask gets into the corner of the eye, doing more mischief than good.

So it is with the roller bandage—good in principle, unreliable in execution.

Another thing of which I want to speak is why I and many others, have abandoned iridectomy as a rule. Iridectomy is certainly advisable in a number of cases, preventing accidents that are worse than the enlargement of the pupil. I must say that I might have done more iridectomies than I have done—ten per cent. Dr. Chisolm says in advocacy of his isinglass plaster that he has no greater number of cases of prolapse, but in his last report there are thirty-three per cent. of iridectomies. The iris which is cut away, cannot prolapse. The number of intercurrent iridectomies in the simple operation must come into consideration.

Dr. J. J. Chisolm, Baltimore:—The report to which Dr. Knapp refers is a hospital report in which are included cases done by my assistants and they do iridectomies. The hospital report does not refer to my individual cases.

Dr. H. Knapp, of New York:—The danger in the simple operation comes from the prolapse of the iris, as it does in the combined operation and the danger from prolapse in the combined operation (the angular incarcerations) according to my experience is greater than the prolapse in the simple operation. Since I abandoned iridectomy, I have seen much less iritis, irido-cyclitis and other complications than before. Simple extraction is, I think, the safest operation and that is its principal claim. When I examine eyes on which extraction with iridectomy has been done by myself or others, I find incarceration of the iris in the corners not so rarely and incarceration of the capsule in the majority of cases. This leads to many reactive processes including sympathetic ophthalmia.

I never cut a prolapse, whether spontaneous or traumatic, unless I get it fresh. If there is blenorrhœa or another infective process, it is criminal to cut a prolapse, as this opens a door for the entrance of germs into the interior. These are only the immediate results of cutting the iris, but the later ones are just as deleterious. In the series of one thousand combined operations which I have reported, there were two or three cases of late suppuration following incarcerated iris. In some cases the incarceration was so small that it could not be seen. As a result of exposure there was purulent iritis and ophthalmitis in eyes that had been quiet for years. Such cases are well known. The danger from immediate prolapse of the iris is greater when the iris is cut than when it is left untouched. Some years ago while engaged in experiments with infective germs, I injected pyogenic cocci into the anterior chamber of rabbits. On examination of these eyes I found the cornea was full of germs, but the iris almost free from them. The iris protects the deeper parts. This fact may serve as a rule for guidance, that we should make an iridectomy only when the eye is still aseptic. Otherwise it is better to postpone the operation until all inflammatory irritation past.

The occurrence of prolapse is chiefly due to two things. The one is *traumatism.* In fifty per cent. of the cases there is a direct history of hurt or blood in the anterior chamber to indicate that the part had been injured. The second cause is a *peripheric section.* The introduction of excision of the iris was not the result of scientific thinking. Iridectomy was made because its originators could not help it. A large peripheric incision without iridectomy is impossible. This is not so when the section is placed in the limbus. As we cannot always be accurate, let us rather encroach upon the cornea than on the sclerotic. On the whole the subject is certainly one that still requires careful study and prolonged experience.

DOUBLE CONGENITAL DISLOCATION OF THE LENS.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY GEORGE FRIEBIS, M.D.,

OF PHILADELPHIA.

On Jan. 3, of this year, the Rev. Dr. B. of Philadelphia, brought his son Walter, now 7 years of age, to me desiring that something be done to improve his sight; stating that for some time past both he and the teacher had noticed that the boy had great difficulty in clearly defining objects, which were easily distinguished by other pupils of his class, at a reasonable distance from him, nor could he well define small letters at the usual reading distance. The examination revealed the rare condition known as congenital dislocation of the lenses; and in this instance the dislocation was symmetrical. I have the honor to show you an excellent drawing, made by Dr. J. Madison Taylor, of Philadelphia, illustrating the conditions. The lens in each eye was tilted upward, slightly backward and inward. The iris was responsive to light stimulation and only on close scrutiny could a slight tremulousness of the same, in the inferior, outer quadrant be detected. The fundus viewed by both the direct and indirect methods showed the curious phenomenon of aphakia with myopic refraction in both eyes. The lower periphery of the upward dislocated lens appeared as an irregularly marked black line. The fibres of the zone of Zinn, described by some observers upon the subject, as clearly discernible in the aphakial interspace, were absent in this case. Owing to the child's unsteadiness it was impossible to measure with accuracy the degree of refraction either of the lens or aphakial portion of the eye. I confess to have been slightly puzzled by the appearance of the lens, viewed by oblique illumination, deeming it at first glance, because of the strong grayish reflex of the lens, though entirely transparent by other methods of examination, a form of congenital cataract. The vitreous body and fundus were normal; the tension likewise. The test for vision in the R. E. = 15-70, L. E. 15-50 imperfectly; a manifest refraction at this time, which was rather hurriedly performed, gave a negative result. Upon a subsequent occasion, the pupils being dilated by atropine, I thoroughly tested his vision with different combinations, sphericals, cylinders and sphero-cylinders + and — which would be too wearisome to enumerate; I found the following formula gave the best results. R. E. S. — 1 = cyl. — 1 ax. 180 = 15-70 *clearly, but in a moment he* would again lose certain letters in the line. L. E. S. — 1 = 15-50 perfectly but as in the R. E. he could not hold the line satisfactorily. A few weeks later on, I again tested his refraction without mydriatic or glasses. At this time vision for distance in the R. E. = 15-70, L. E. 15-50 imperfectly, these tests proving conclusively that the child was also amblyopic; a usual concomitant of congenital dislocation. Vision for reading was not improved by glasses in the slightest degree. In fact vision for small letters at about 8 inches was slightly better without glasses and he defined letters Snellen 1 at 8 to 10 inches fairly well, but had to search for them, this showing an amplitude of about 2 inches in each eye and that accommodation was not entirely abolished. Glasses were not prescribed. The field was tested and found to be normal; the color sense was unimpaired. Diplopia usually present and demonstrable in many cases of this character could not on account of the youth of the patient and some mental obtuseness be established.

In passing I would state, that Dr. Chas. S. Turnbull also saw this little patient with me but by no method of examination could we detect any other structural changes than those already mentioned. Both parents are healthy and have a family of nine children, all of whom have excellent vision. As some observers hold that congenital dislocation is largely due to heredity and that consanguinity often plays an important part in its causation, I closely questioned the father, a very intelligent man, as to his family history. I could not obtain a satisfactory answer confirmatory of his theory, but he stated that he had no definite knowledge of any hereditary tendencies in his wife's family. The late Dr. Wm. S. Little of Philadelphia, reported at the 19th meeting of the A. O. Society two cases of congenital dislocations of the lens, one was non-symmetrical and the other symmetrical. The latter case occurring in the practice of Dr. Turnbull, by whose courtesy I am enabled to show you an additional cut representing a double inward dislocation. Although this cut was shown at the meeting of the American Ophthalmological Society in 1883, yet I deemed it of sufficient interest, by way of contrast with my own case, to bring it to the attention of this meeting. Both patients were likewise markedly amblyopic and in each instance refraction of the existing ametropia gave a useful degree of vision. In Dr. Turnbull's case the lenses were so far dislocated as to make the eyes almost aphakial, but by the use of cataract glasses useful vision was obtained. Dr. Turnbull's patient gave no history of malformations in any of the members of his family or near relatives, but had himself a highly vaulted roof of mouth. Dr. Little's patient said that he had a cousin similarly affected and that his father was color blind. These are the only two cases that I have been able to find in the more recent literature within the past decade, clearly recorded as congenital dislocations, although foreign literature teems with a goodly number of this congenital aberration. Dr. Doensch in an admirable monograph enters at some length into the history of the subject, in which it appears, that earlier writers made no marked distinction between congenital and spontaneous dislocations, both being looked upon by the majority of observers as indicative of a morbid process. Not until Sippell's excellent essay upon the subject, who was himself afflicted with congenital dislocation, was a distinction made and the diagnosis accepted, that one was a morbid condition in which the lens was liable to further degeneration, such as sinking of the lens and loss of transparency, etc., while congenital dislocation is a permanent condition not likely to undergo such changes, and in which heredity and consanguinity are the most probable etiological factors. In support of the theory of heredity, Sippell quotes a number of cases, three of von Graefe's and three of his own, in which the condition was found to exist in one instance and in the others traceable to father and daughter. Graefe, Sippell, Dixon and other authors give strong support, in my opinion, to the heredity theory; a number of cases are reported of brothers and sisters of the same family, who were so effected. In Jonathan Wild's interesting little book on "Congenital Malformations of the Eye," which was kindly brought to my attention by Dr. Oliver, a member of this Society, I found four cases, which he quotes from Dixon, all occurring in the same family, and though the history of the case presented by me does not sustain the theory of heredity, it is but an isolated case and an exception to the rule, and my conclusions based upon a brief study of the literature of the subject, I would formulate as follows:

First, that congenital ectopia lentis is usually double.

Second, that it is a congenital malformation, the cause of which is not yet positively established.

Third, that amblyopia and ametropia are always concomitant conditions and that the majority of cases, so far reported, sustain the theory of heredity as the primary cause.

Discussion.

Dr. D. C. Bryant, Omaha:—I have under my care a family of seven persons, five of whom had the same trouble, dislocation of the lens. The parents have healthy eyes. In another family the mother and three children suffer with the same trouble. There is no myopia in these cases.

Dr. B. Alexander Randall, Philadelphia:—I remember seeing two cases of this condition it Jeager's clinic on the same day. In one the dislocation was up and in the other up and to the left. The point was made by Jeager that he regarded the symmetrical displacement as congenital, and the other as probably of traumatic origin; and I would ask if those of wide experience can throw light upon this question, which my own observation would leave an open one.

Dr. Edward P. Morrow:—It has been my fortune to see four cases of dislocation of the lens and to receive the history of another in the same family. The drawing shown is a perfect picture of the first case seen, a boy about 12 years of age having a double dislocation upwards and inwards. Shortly following this his sister presented herself, showing precisely the same condition, again inside of the year another sister and the mother similarly affected. From the mother, a history was obtained of her sister, whom she said was affected in a like manner. Each of these cases would accept either a convex or a concave lens with slight improvement of vision. There was no movement of the lenses obtained in any of the cases.

Dr. Eugene Smith, Detroit:—It may be of interest to speak of a case of voluntary dislocation of the lenses that has come under my observation. When the individual tipped his head forward both lenses would come through the pupils, when he threw his head back the lenses would return. I advised iridodesis and in the meantime used eserine. He went to New York where operation was advised against and pilocarpine prescribed.

Dr. George Friebis, Philadelphia:—The remarks which have been made are corroborative and sustain the views I have expressed, that heredity is the most prominent etiological element in the production of this condition.

INFANTILE CATARACT.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association. held at Detroit, Mich., June, 1892.

BY ALBERT R. BAKER, M.D.,
OF CLEVELAND, O.
PROFESSOR OF DISEASES OF THE EYE, EAR AND THROAT, IN THE MEDICAL DEPARTMENT OF WOOSTER UNIVERSITY; OCULIST AND AURIST TO THE CITY, WOMEN AND CHILDREN'S AND UNIVERSITY HOSPITALS.

I selected this subject, not because I had any new facts to communicate or new operations to propose, or new theories to advance; but because my experience, observation and reading has led me to believe that, as a rule, we do not treat infantile cataract as successfully and as intelligently as we do many other eye diseases. If I am correct in this supposition, an interchange of ideas on this important subject at this time cannot fail to be of value.

I know of no subject more perplexing to the medical student than the classification of cataracts; they have been classified as to age as congenital; infantile, juvenile and senile, as to consistency as fluid, soft, mixed and hard. They may be capsular or lenticular. Capsular cataracts may be pyramidal anterior polar, posterior polars, or degenerative. Lenticular cataracts may be nuclear, cortical or zonular. Cataracts have been classified as to cause, as albuminuric, diabetic, traumatic, etc. They may be simple or complicated, primary or secondary, ripe or unripe, mature, immature or hypermature. This list might be continued almost indefinitely, but is sufficient to illustrate the protean forms in which lenticular opacity presents itself to the ophthalmic surgeon, and it is in the child that we find the most remarkable variation, in the cases brought to our notice. It was that prince of British ophthalmologists, Mr. George Critchett, in a lecture published in the *London Lancet* as long ago as 1855, who said that "Congenital cataract deserves very careful notice on account of the numerous aspects it assumes, the frequency with which it is overlooked, the baneful influence it may exert upon the prospects and career of the patients, and the favorable results of suitable treatment. The more we have an opportunity of observing these cases, the more evident does it become that nature revels in variety. Even in her morbid operations, when we fancy we have exhausted every possible form, some new manifestation presents itself."

For our present purpose it is not necessary to enter into an extended discussion of that much debated question, whether cataract is ever congenital, as it makes little practical difference (although the question may have an etiological value), whether it is present at birth or comes a few hours or days afterward. Dr. Alt[1] saw a case of total lenticular cataract in a baby 24 hours old. The writer saw a milky white lenticular cataract of one eye, other eye normal, in a child 24 days old. The mother and an intelligent nurse said the opacity was present at birth. Granting that cataracts may be congenital, it seems to me more desirable to substitute the term "infantile cataract," so as to include all those occurring in infants and young children. Practically many of these cases do not come under the observation of the oculist until later in life, often being overlooked until 5, 10, and even 15 or 20 years of age.

---

[1] American Journal of Ophthalmology, December, 1887.

The most frequent form of infantile cataract is the lamellar or zonular. These cases are not infrequently associated with other congenital defects, the intellectual faculties often being very imperfect. Mr. N. C. Macnamara,[2] in his Presidential address to the Ophthalmological Section of the British Medical Association, remarked, in opening the discussion of this subject, that "it was well known that in fœtal life branches of the hyaloid artery covered the posterior surface of the lens, and advanced forward over its margin, helping to form the membrana capsula pupilars. If, from fault in the development of the eye, this vascular layer persisted after birth, it was apt to give rise to a film of connective tissue, extending to a greater or less extent over the posterior surface of the lens, and so forming a zonular cataract. In some instances a small patch alone was left to mark the spot at which the hyaloid artery had passed on to the lens, in other cases a central opacity existed, with radiating bands stretching toward the periphery of the lens. Microscopical specimens have demonstrated the fact that some of these zonular cataracts consisted of a film of connective tissue, together with remains of the hyaloid artery." This seems to be the most satisfactory explanation yet offered of the pathology of zonular cataracts, and it seems much more rational to attribute the convulsions which have figured so largely in the literature of this subject to the same cause which brought about the defective development of the lens, the defective mental faculties, and the other bodily defects so frequently seen in these cases. An attempt was made to secure statistics bearing upon the relative frequency of cataracts associated with hare-lip, cleft palate, coloboma of the iris, total absence of iris, spina bifida, etc.; but could find nothing satisfactory. I regret exceedingly that I have not kept more accurate records of these cases occurring in my own practice, and yet the experience of any one man, unless he had exceptional advantages for observation, would not include enough of these cases to be of much practical value. Upon referring to my case books I find records of only two cases of congenital total absence of the iris, and in both of which cataracts were present. One of these had interstitial keratitis and typical Hutchinson teeth. The other was confined to a penal institution and a confirmed criminal. One lens was partially dislocated, and by throwing his head backward in a peculiar jerky manner he could throw his lens partially back like a door, out of the visual axis, and thus secure a fair amount of useful vision. He said his father's eye had just the same appearance. Of nine cases of coloboma of the iris two had cataract. I have met with two cases of cataract associated with hare-lip, and one with spina bifida, and a number of cases had Hutchinson teeth.

If time permitted, it would be interesting to consider hereditary influence in the production of zonular cataract. A few years since I was called to operate upon three brothers, aged respectively 11, 21 and 29 years. There was one other son and three daughters in the family whose eyes are normal. The parents were cousins and one grandparent had senile cataract, otherwise the family history is good.

Next frequent to the zonular in infants is the anterior polar or pyramidal cataract. Notwithstanding the great diversity of opinion as to the etiology of these capsular cataracts, I have no doubt but that they are nearly all due to a perforation, or at least inflammation, of the cornea. It is not necessary that any corneal opacity should be present. About two years ago a child was presented at my clinic, 2 months old, with a history of having had a severe attack of ophthalmia neonatorum, with perforation of both corneæ. There was a dense white corneal opacity, including nearly the whole cornea, so that it was impossible to see the pupil of either eye. In the course of a few months the corneal opacities cleared up so that typical anterior polar cataracts could be seen, which were removed by the suction operation. At present there is no corneal opacity, and it would be impossible from any examination to say that there had been a perforation. It is surprising that so accurate an observer as Dr. Alt[3] should not have seen such cases.

Not infrequently the lens undergoes degenerative changes, its fluid constituents become absorbed, leaving behind a tough dense membrane often containing more or less calcareous substance. I have met this condition most frequently in traumatic cases or in cases which have been operated upon repeatedly by the needle operation. I have come to look upon the usual needle operation as a frequent cause of this condition. How often after needling an infantile cataract several times have you found the pupil still occluded with the dense white remains of the capsule and shrunken, possibly calcareous lens, through which you have been able with great difficulty to tear a hole—a poor excuse for a pupil, but you congratulate yourself upon securing even that? This has been my unfortunate experience so frequently that I have almost abandoned the needle operation in cases of zonular as well as in pyramidal cataracts. After trying several operations my preference is for the linear extraction combined with the suction operation with Mr. Teale's instrument, in which the suction is made by the mouth of the operator. I have never been able to get a Bowman syringe that I could use so well.

The anterior capsule should be divided in both the verticle and horizontal meridians the full extent of the dilated pupil, and the lens pretty thoroughly broken up, but avoid perforating the posterior capsule. Keep the pupil well dilated, and in from three to five or six days, possibly seven, make a broad incision at the outer part of the cornea about two or three lines from the sclero-corneal margin, with the keratome. In many cases by partially withdrawing the instrument and pressing it backward, and as the aqueous escapes, the softened lens matter runs out almost of its own accord, the remaining portion if any, can often be coaxed out with a little stroking of the opposite side of the cornea with the spatula. If there is a hard nucleus it can be delivered in the usual manner. If the pupillary area can not be thus readily cleaned the suction curette can be inserted, and by sweeping it around carefully the remaining cortical substance can be removed. Care should be taken not to injure the iris. In one instance in which I made the incision near the sclero-corneal margin, I had a slight anterior synechia, and the pupil is slightly oval in shape, but otherwise there have been no untoward symptoms. Since this accident occurred I have made the incision in the cornea further forward, and the danger of synechia is lessened, and the lens substance removed more easily; mydriatics can be used much more freely so as to keep the pupil well dilated without danger of prolapse. By this method patients are discharged in from two to three weeks, which under the old method would have occupied months, and often valuable time in the child's education sacrificed. In very young children on account of the difficulty in managing the patient, it may be preferable to resort to the needle operation. In these cases there is not the same necessity of securing useful vision at once, and yet in cases showing a disposition to develop nystagmus, I very much doubt the propriety of wasting time to allow the lens to absorb when it can be removed so easily. The lens however, is absorbed much more quickly in those cases than in older children. I have followed the rule applicable to senile cataract, and operated but one eye at a time, and have several times questioned the advisability of making an iridectomy, and of permitting the lens to remain in one eye so as to allow of a certain amount of accommodation for near work.

---

[2] British Medical Journal, September 12, 1891.

[3] American Journal of Ophthalmology, December, 1887.

I have under my care now, a bright little boy six years of age, whose vision in left eye was $\frac{5}{200}$ increased by dilating the pupil to $\frac{15}{200}$, in the right eye $\frac{20}{200}$ with pupil dilated increased to $\frac{20}{70}$. I removed the lens of left eye by the method detailed above, and secured vision $\frac{20}{20}$ with + 10 D. Before the operation there was considerable nystagmus which has all disappeared. When the pupil of right eye is dilated with cocaine he can read Jaeger No. 3, and has considerable amplitude of accommodation, especially for larger type.

I should be pleased to know if any of the members of the Section have had any experience in this direction. Would the amount of accommodation in such an eye be of any practical advantage to the patient, and if so, would it be enough to compensate for the deformity of an iridectomy?

Would there be any objection to postponing farther operative interference until later in life, when the patient could express an intelligent opinion on the subject?[4]

It has been my custom to recommend operation within the first year. I operated upon one case at two months. There are cases which it may be advisable not to operate upon at all.

A doctor friend of mine has a typical anterior polar cataract of both eyes, so prominent are they, that he always wears colored spectacles when in company, to hide them. He completed a regular collegiate course, graduated in medicine, and is now doing a large general practice.

If operative interference is decided upon, the question is to be answered whether the lens is to be removed or an iridectomy is to be performed.

I have followed the rule laid down by my old instructor, Mr. Streatfield, and removed the lens in all cases in which the vision could not be improved, by suitable correction of refractive errors, with the pupil widely dilated to $\frac{20}{50}$. Practically, this rule has left but few cases for iridectomy, and those cases in which I have made this operation have been rather disappointing in results, and in several instances a subsequent removal of the lens became necessary.

In conclusion I will offer the following for your consideration:

1. Infantile cataracts should be operated upon early, within the first year if possible.
2. In pyramidal and zonular cataracts in which vision cannot be improved to $\frac{20}{50}$ after fully dilating the pupil, removal of the lens is to be preferred to iridectomy.
3. Fluid cataracts are best removed at once by linear extraction.
4. Soft cataracts including zonular and capsular, are best treated by first breaking up the lens thoroughly, and removing a few days later by the combined linear extraction and suction operation.
5. Simple decision is sufficient in very young infants, unless nystagmus should be present.
6. Only one eye should be operated upon at a time.
7. There are a few cases in which it may be advisable to extract one lens for distant vision and make an iridectomy on the other eye, so that a certain amount of accommodation may be preserved for near work.

Discussion.

Dr. B. Alexander Randall, Philadelphia:—The point was raised in the paper in regard to zonular cataract as examined with the microscope, *that a portion of the hyaloid artery of the fœtus had been traced into the cataractous zone.* This matter has escaped my observation, and is contrary to anything that I have studied in the matter. I would ask if I heard aright. The hyaloid artery with its capsular and pupillary net-work is wholly external to the lens-capsule, and I cannot conceive of its having any connection with the opaque laminæ of lens-substance within.

Dr. A. R. Baker, Cleveland, Ohio:—I have presented this paper not so much because I had any new ideas to advance as with the hope of gaining some information upon the points presented. In reply to the question of Dr. Randall, I would say that I am indebted to Macnamara for that point in regard to the remains of the hyaloid artery being present in these cases He says that microscopically, remains are to be seen in many of these cases.

INJURY TO THE LENS WITH CASES.

Read before the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, at Detroit, Mich., June 7, 1892.

BY B. L. MILLIKIN, M.D.,
OF CLEVELAND, OHIO.

I desire very briefly to call your attention to a class of cases of great frequency, especially in large manufacturing districts, and which we are all continually being called upon to treat. In few text books do we find any adequate consideration of this important subject, and I scarcely know of any English work on Ophthalmology which is particularly explicit about injuries of the lens, or lays down good rules for the management of such cases. While time will not permit us to enter upon a full discussion of the topic, I have thought the consideration of a few of the more important points might not be without interest to us as specialists or as general practitioners.

Few things are more demoralizing to a patient than to suddenly find he has lost his eyesight, and few accidents can more excite our sympathies.

---

[4] I think Mr. Critchett suggested this procedure many years ago, but I could find no record of cases in which it was practiced.

From a clinical standpoint we may divide the injuries of the lens into two classes, viz: those where the chief injury is to the lens mass itself, and second where there is, in addition, a grave lesion of other structures of the eyeball, the latter class comprising a much larger proportion of all the cases with which we meet. In the first class are comprised such injuries as bits of steel or iron lodging in the lens substance, spicules of iron penetrating the cornea and the lens, but not remaining,etc., and these producing very different lesions,depending upon their size,form and the force with which they enter the eye. When these penetrate the lens and enter the vitreous humor, another class of complications arises, depending upon the ultimate lodgment of the foreign body. The second class of cases comprises a series of injuries of great importance and variety, depending entirely upon the structures involved, the most serious of which are those associated with injuries to the ciliary body, which are always very grave; also, the results of injuries due to puncturing substances will depend materially upon whether the foreign body remains within the eye, or not. The seriousness of the injury of the lens will likewise vary according to the age of the patient, destructive changes being much less likely to occur in young patients than in those older. Almost all injuries of the lens are liable to terminate in traumatic cataract, more or less complete, depending upon the amount of disturbance of the lens substance, and especially the capsule.

In the early history of an injury to the lens, the diagnosis is usually not difficult, and by dilating the pupil with a few drops of cocaine or homatropine, a clear view of the lens with the ophthalmoscope, or with the oblique light will usually serve to locate the position of the foreign body, if present. If, however, there has been in addition, extensive injury to the iris or ciliary body, the location becomes difficult, or impossible, depending upon the amount of hæmorrhage and other disturbances to the structures. A day or two after the injury, even in cases where the foreign body has been very minute, with the ophthalmoscope the course of the foreign body may be made out by a line of opaque matter in the lens, so that one can very readily trace through this substance the course of the offending body.

The progress of the development of traumatic cataract varies greatly in different cases, usually depending, in all probability, on the extent of the lesion of the capsule. Very often the extent of the opaque portion of the lens changes rapidly, and frequently opaqueness of considerable extent will be rapidly absorbed, leaving the lens clear. Sometimes a spicule of iron which penetrates far into the body of the lens will leave no prominent opacity, the track clearing up completely, as in one of the cases which I shall report. In other cases, an opaque line, marking the course of the foreign body may remain for years, and if near the periphery of the lens, will produce no permanent interference with vision. I have selected the following cases as illustrating various injuries of the lens, and which may serve as types of a very large class.

Case 1.—On the 2nd of July, 1888, V. L., æt. about 40 years, a machinist, was struck in the left eye by a long sharp splinter of steel,which was pulled out by a fellow workman. The foreign body entered the eye just below the lower border of the pupil, perforating the iris, and penetrating deep into the lens. Just after the injury, vision was diminished very considerably, but at the time of the examination, he had the following vision: O. D. V. = 6-6 ? O. S. V. = 6-9 ? Under a few drops of a solution of homatropine the pupil dilated, irregularly, and only to a slight degree, although the drops were used several times. On the cornea was a speck or scar marking the entrance of the foreign body, and directly behind it a point in the iris, but with the ophthalmoscope I was unable to detect, at the time, any evidences of penetration of the lens. Atropia was prescribed, to be used three times per day, and a compress and bandage applied. On the following day the pupil was found to be irregularly dilated, being adherent in the lower portion to the capsule of the lens. The ophthalmoscope showed clearly a line of striation, the opacity through the lower portion of the lens being very perceptible. A week later the eye was much better, and showed but little opacity in the lens, only a fine striated line through the lower edge of it where the foreign body had penetrated,and the pupil was dilated ad maximum. Vision was normal.

Case 2.—I have reported this case in full elsewhere,[1] and shall here only refer to the points of interest in this connection. On the 18th of March, 1871, a piece of cap from a musket entered the eye of E. M. O., now æt. 33 years, penetrating the cornea at the outer margin of the right eye, cutting through the iris to the outer border of the lens. At the present time, his vision, after the removal of the foreign body from the posterior chamber, is sufficient for all ordinary uses. The ophthalmoscope shows, in the line of the wound through the lens, a dense white opacity, simply covering an area as large as the original injury to the lens structure must have been, and in all these years there has been no additional development of the traumatic cataract.

Case 3.—The following is an example of a very frequent accident. H. T., about 12 years of age, while shooting a small toy cannon, received an explosion of powder in the face, the eyes being thoroughly peppered, and many pieces were removed from the cornea of both eyes. The corneæ were so opaque that a careful examination of the anterior chambers was difficult or impossible. Three weeks after the injury, when the corneæ had cleared up, it was found that a small grain of powder had entered the anterior chamber of the left eye and evidently wounded the capsule of the lens,having also penetrated the pupillary border of the iris, this being found attached to the capsule, with a considerable area of the lens adjacent to the foreign body opaque. Under the alternate use of atropia and eserine the iris was almost completely separated from the capsule, and the lens matter has gradually cleared up, until at the present time there remains only a slight opacity on the capsule, with the small powder grain still showing, and V. = 6-6 ? although the opacity is located just at the lower border of the pupil.

Case 4.—On the 18th of May, 1891, Miss E. B., æt. about 20, came to me with the following history: On that morning, while passing through a field, and over a barbed wire fence which had fallen to the ground, she felt something strike the right eye, which she thought might be one of the barbs of the wire, but was unable to say definitely. Immediately she noticed that she could not see, and this was followed by severe pain in the eye and head. Upon making an examination, I found in the centre of the cornea a vertical wound, ragged in appearance, perforating the cornea, some of the lens matter having escaped into the anterior chamber. T = — 2.

Atropia was instilled into the eye, and a compress and bandage applied, after carefully cleaning the eyeball and lids. On the following day the pupil was well dilated, regularly, and the ophthalmoscope, and oblique illumination showed clearly the wound in the cornea and in the capsule of the lens just below the centre, with the extruded lens matter, which was very slight in amount. The lens showed a number of striæ, running from the centre regularly to the periphery, like the spokes of a wheel. On the first of June following, the striæ in the lens were clearing up, very evidently being smaller and less opaque, while the spot in front of the lense was smaller, and the lens matter in the anterior chamber had entirely disappeared, leaving simply a large spot in the front of the lens and capsule. She then counted fingers at eight feet. By the 28th of August, nearly all the striæ had disappeared, leaving only a small roundish opaque spot in the lens capsule, together with a corneal scar, and the pupil was fully dilated. I have since heard, but have had no opportunity of making an examination, that the vision of the eye had again failed. Probably there has been a redevelopment of the traumatic cataract.

---

[1] Trans. Am. Oph. Soc., Vol. V, p. 565, et seq.

Case 5.—The following case is of interest on account of a somewhat similar accident occurring to each eye at considerable intervals. On the 3rd of April, 1890, I was called in consultation to see J. D., æt 21, from whom I elicited the following history: Ten days ago he was struck in the left eye with an iron burr, which produced a lineal wound of the cornea, evidently cutting or rupturing the capsule of the lens, as there was much inflammation of the eye; but it is now quiet and he has not had great pain. T = n. Lens is swollen up very largely, filling almost completely the anterior chamber, and attached to the edges of the pupil; pupil fairly well dilated under atropine. Under cocaine, the lens matter in the anterior chamber was removed by an upward incision with the keratome, leaving the pupil fairly clear, but still some cortical matter remaining. Atropia was used to keep the pupil dilated, and a compress and bandage applied for a few days. On the 2nd of May following, there was considerable opacity in the pupillary space, so that the details of the fundus could not be made out. Under cocaine another operation was performed breaking up the soft lens matter and slitting up the capsule, after which patient could see fingers readily and the eye continued to do well. At present, with +14.00 D's glass V = 6-6?

On the 6th of April, 1891, while working in boiler works, he was again struck with a bit of steel, in the right eye, which produced a vertical wound through the corneoscleral junction at the lower outer quadrant, and the anterior chamber was filled with blood. Three days later, an examination with oblique light disclosed striæ in the lens; pupil partially dilated with atropia, but eye doing very well. Evidently the traumatic cataract was developing rapidly, with little or no pain. By the 14th of May, the eye had improved very satisfactorily, the wound being well closed, the irritation having greatly subsided, leaving the pupil somewhat irregular in shape with attachments in the region of the wound. The ophthalmoscope showed the middle portion of the lens clearing, but with a more dense opacity directly behind the seat of the injury. Two weeks later the lens had cleared up almost entirely in the central portion, leaving the opacity confined to the neighborhood of the injury, and the outlines of the fundus could just be made out with the ophthalmoscope, and V = 6-60. By the middle of December following, sight had failed very materially, and he was then able to count fingers only at six feet, and the traumatic cataract was again developing, and now had involved almost the whole lens.

Case 6.—On June 1, 1892, W. H. B., æt. 25 years, came to me with the following history: On the 26th of March last was struck in the left eye with a small piece of steel, which he thought did not enter the eye, but was unable to see after the accident. Immediately after the accident there was no pain, so that he continued his work from the time of the injury, in the morning, until late in the evening, before consulting a physician, nor has there been much pain since. The physician who first saw him sought for the foreign body, but did not succeed in removing one. A short time afterwards an operation was made for the removal of the opaque lens matter, but he has been unable to see, except bare outlines of objects in the outer portion of the field. At present the pupil is fairly clear; there is an irregular ragged scar of the cornea, probably produced by the foreign body. The iris is adherent above, and with the ophthalmoscope we are unable to see the deep structures of the eye at all, on account of the dense opacity of the vitreous. T + 1.

The eyes remain very sensitive to both light and use, in near work, to the present time. The probabilities are that the foreign body remains in the deep portion of the eyeball, and may yet give serious trouble.

As to the prognosis of all injuries of the lens, whatever may be their extent, we must consider it essentially grave, and out of all cases, very few escape without some permanent damage to the lens structure; but we believe that much can be done in the way of treatment and management of such cases immediately after the injury, or for a long time subsequently, in preserving the proper function of the lens and eye. In young persons especially is this true, and by promptly putting the organ, as well as the patient, at rest, in many such cases, great good can be accomplished. After a considerable experience with injuries of the lens, I am convinced that the rest afforded by complete paralysis of accommodation is of the utmost advantage, as protecting the lens tissue from the disturbances which necessarily must arise from the effort of using the eye.

Our treatment must be based upon a somewhat different principle in the cases of the young and the old. Of course in all cases of foreign bodies in the eye, whether the lens is injured or not, the first requisite is the removal of the offending body, if possible. The next most important step in the treatment of such cases must be the institution of absolute cleanliness, and every organ which has been so injured should be thoroughly cleansed by means of aseptic or antiseptic washes. For this purpose, simple boiled water may be used freely to wash out the eye, or solutions of boracic acid and bichloride of mercury, 1 to 5,000, for the same purpose. With the ordinary medicine dropper and any of these solutions, together with pledgets of absorbent cotton, the wound can be thoroughly cleaned, thus preventing very largely the danger of infection. One of the great dangers and sources of annoyance in all these cases where the point of injury is in contact with the iris, is the plastic adhesion of the iris to the lens, thus producing a perpetual focus of irritation, so that to avoid this tendency, I believe it is of the greatest service to use *a solution of atropia sufficiently strong to dilate* freely and thoroughly the pupil, and thus keep the iris out of harm's way, as well as giving complete rest from the disturbances due to accommodation. I believe that in younger persons particularly, there is little or no danger of development of glaucomatous symptoms, which some authors seem to fear so much. These symptoms are largely, if not entirely, produced by the swelling of the lens, thus forcing the iris into the outer angle. If glaucomatous symptoms do arise from the escape of the lens matter into the anterior chamber, or from its swelling due to its contact with the aqueous humor, one can readily resort to the evacuation of the contents of the anterior chamber, and so obviate the increased tension from this source. I believe it, therefore, to be the part of wise and conservative surgery, in all injuries to the eye of any considerable magnitude, to put the patient at rest—in bed if necessary—to put the accommodation completely at rest, and to put the sound eye as well, preferably by bandaging both eyes for a few days. I am convinced that by keeping such an eye completely at rest, for some weeks if necessary, very favorable results will often follow. I have no doubt that the primary clearing up of the cataractous condition of some of these cases which I have reported, has been due to the continuous use of atropia, even after all indications of the external wound have disappeared, except the cicatrices, and that the redevelopment of the cataract some months later was due to the excitation produced by the use of the organ. I could see no great objection to keeping up for an indefinite time the use of a mydriatic, without danger or inconvenience, except as may sometimes arise from its local irritation. Of course it is often difficult or impossible to maintain control of patients for a sufficient time under such circumstances. Compresses and bandages I should continue only until the external wound had healed, except in some cases where there has been much hæmorrhage, in which absorption takes place more rapidly under moderate pressure. In many cases with iritic attachments, much can be done to loosen or break them up entirely by the alternate use of atropia and eserine, thus leaving the eye less liable to recurring inflammatory attacks.

Of the methods and time for removal of traumatic cataract, it is not necessary to speak, as our object has been rather to point out or indicate the treatment of cases prior to the necessity of operative interference.

In old people the use of mydriatics must be watched much more carefully, for in these the development of glaucomatous symptoms is very much more to be feared, while on the other hand, the condition being so much less active in these patients, this source of annoyance becomes proportionately less, depending upon the age of the patient.

Discussion.

Dr. S. C. Ayres, Cincinnati, Ohio:—I have been much interested in the paper, and particularly with that portion which related to partial opacities of the lens. I have seen quite a number of these cases, and they have always excited my surprise and interest. We are taught to believe that injury of the lens capsule is certain to produce opacity of the lens, swelling and the consequent results. I have seen a number of cases in which there were limited opacities of the lens, and in which in all probability, foreign bodies had penetrated to the vitreous, and had left limited opacities in the lens and capsule. It is not easy to explain these cases. It serves to show the healing properties in the capsule, and it shows that very often it will close up when wounded.

Dr. Edward Jackson, Philadelphia:—I was much interested in that portion of the paper which referred to the retention of vision through an injured lens. I recall one case that came to me when 82 years of age. There was a history of an injury in boyhood. There was a scar on the cornea and corresponding portion of the iris and opacity of the corresponding quadrant of the lens in which there had probably been a penetrating wound. He said that vision had not deteriorated since immediately after the injury. I watched the case for eight years longer, and the other lens was becoming more opaque, but the changes in the injured eye were not more rapid.

Another case that I have seen within a year, was one that came with a history of injury and penetrating wound with immediate impairment of vision; then subsequent improvement, followed by deterioration commencing again within two or three weeks. In this case there had been, over a year before, a penetrating wound of the cornea and iris, and I have no doubt of the lens. When the patient first presented, the details of the fundus were so far veiled that only the larger vessels could be seen. Within a month the lens was entirely opaque. This case is quite similar to one mentioned by Dr. Millikin.

The most interesting case of this kind that I have seen is one now under observation. The patient is six years of age, and has double congenital dislocation of the lens. The lower margin of the lens coming back of the pupil, prevents anything like distinct vision. There were slight opacities in the lenses. I undertook to needle one of them. I needled it four times, the last two times very freely; and within two weeks, six weeks after the last needling, there is no general opacity of the lens. Twice I passed the needle entirely through the lens, and after the operation could see its track. That track almost entirely cleared up. Just at the point where the wound was made in the capsule, a little mass of opaque lens-substance projected, and in the lower quadrant of the lens there is a marked notch showing there has been some absorption, but the mass of the lens still remains clear.

Dr. G. A. Aschman, Wheeling, W. Va.:—I was much interested in that part of the paper which showed that often there is little trouble after injury to the lens. I recently had under treatment a man 50 years of age, who had lost one eye several years before. He had a ripe cataract in the other eye with a history of injury. After the injury he noticed a decrease of vision in the eye and was treated by a physician for two weeks only, when he returned home without further trouble than a gradual loss of sight. I examined the cornea carefully and found a very slight scar and as he was at an age when we should expect senile cataract, I decided to operate. I made the extraction and found in the lens a very small particle of iron. The operation was done six months after the injury, and as V. = 20-30 resulted, he was able to perform all work as well as ever.

Dr. Eugene Smith, Detroit:—I can bear out what has been said about punctured wounds of the lens occasionally clearing up without cataract or destruction of the lens. I have in mind two cases. A child ran a needle through the cornea penetrating the lens. Following this there was opacity about the size of the needle extending nearly through the lens. This entirely cleared up as did also the opening in the capsule. The child now has normal vision.

In the second case a piece of wire 1-24 of an inch in diameter was thrown across a room and struck a young lady in the eye. It went through the cornea and penetrated the lens. I expected that there would be a cataract. The opening healed up and in the course of one or two weeks the opacity disappeared. Vision is normal.

Dr. Lippincott, Pittsburg:—I have seen several cases in which injuries to the lens gave rise to very little permanent trouble. One was that of a young lady, who while chipping off the irregularities from the inside of a piece of pottery was struck with a minute piece of steel from the chisel. The foreign body, which was found lying upon the lens in the centre of the pupillary space, was removed with a Gruening's magnet. The ultimate result was normal vision.

In another case a spicule of copper about the thickness of a No. 5 sewing machine needle and three or four mm. long, had entered the anterior chamber and was found sticking in the lens substance near the edge of the pupil. The splinter was removed with a pair of smooth iris forceps through an incision at the corneal margin. A slight and sharply defined opacity of the lens remains, but fortunately it is not central, and the vision is as good as it was before the accident.

Dr. B. L. Millikin, Cleveland, Ohio:—The point in which I have been particularly interested is in regard to the after treatment, and the effect of atropia in paralyzing the accomodation in getting rid of the action of the ciliary muscle and what influence this has upon the after effects of these injuries. That is a point of a good deal of interest and it seems to me that in some of the cases where the amount of clearing up has been great, the atropia has been of great advantage by the complete rest which it has afforded. The point I wish to emphasize is the effect of absence of the accomodation in clearing up the lens matter after these injuries. Some of these cases have had extensive opacities and within a few days one half of the lens has become opaque. Within two or three weeks or less, the opacities have disappeared almost entirely so that the fundus could be made out. The question is whether or not if the mydriatic had been kept up for several weeks or months, it would not have effected a continuance of the clearing up of the lens, and it might not have remained clear.

EYE INJURIES CONSIDERED IN RELATION TO SYMPATHETIC AFFECTIONS.

Read before the Section of [illegible] Forty-third Annual Meeting of the Ameri[illegible] held at Detroit,

BY T. E. MURRELL, M.D.,

OF LITTLE ROCK, ARK.

It is a difficult matter in many cases of recent injury to an eye to foretell the effect it will have on the fellow eye if it be not removed. There are numerous injuries that do not at first appear very serious, and there are good reasons for believing that not only may a good looking globe be preserved, but practical vision as well, which may finally prove very dangerous; while others that seem to doom the eye to sure destruction, as well as endanger the other eye, sometimes take a different course to our surprise.

We have had practical demonstrations of this in cases where our advice to remove the injured eye has met with refusal, and years afterward the person has been found still carrying it without the slightest trouble, much to his boasting and not much to our credit in his conception. Nevertheless, we know the slumbering dangers in these eye injuries that may awake after long years, and our boasting patient may yet come to grief. Injuries that threaten danger to the fellow eye, may be divided into two general classes; those in which a foreign body lodges within the globe, and those in which the globe suffers violence from without.

Every one must at times be struck with the remarkable difference in tolerance of eyes to injuries. and it may be considered a fair rule to estimate the danger to the uninjured eye by the speediness and grade of the reaction in the injured eye. Yet we know that in these violent processes in which the entire uveal tract is speedily involved in suppuration there is less danger of sympathetic trouble than in the less severe and more insidious cases. The eye is peculiarly rebellious to the intrusion of a foreign body, and it is rare that such an occurrence does not only entirely destroy the eye thus entered, but finally leads to sympathetic involvement of the other eye. As is well known some portions of the eye are far more intolerant of the presence of foreign matter than others; this is peculiarly true of the ciliary body and the vitreous.

Just why the vitreous should be so ready to revolt at intrusion is hard to explain since it is not endowed with nerves or blood-vessels, but we know that the tiniest particle of matter lodged in it is almost certain, sooner or later, to be followed by severe reaction. Of course the injury done to other important parts, as iris, lens and ciliary body in its route to the vitreous, is to be considered, since reaction may first set up in them, but in many instances they escape and only the sclera and choroid are penetrated, which readily heal, and the reactionary process afterwards ensues in the vitreous. It is commonly believed at the present day that the reaction is the result of microbic infection introduced with the foreign body, or entering along its track from the conjunctival sac. If this be true, on what principle can we explain the want of reaction and final restoration of normal function with perhaps excellent vision when the foreign body, for instance a bit of steel, has been successfully removed with the electro-magnet? Certainly all the germs are not brought away with the body; and the wound is greatly enlarged to introduce the magnet, thereby increasing the danger of invasion from without. Then again, observation shows that there is some property in the intruding body itself, perhaps of a chemical nature, that determines very largely the tolerance of the eye to its presence. In former years when percussion caps were used many accidents happened to eyes by fragments of the cap being driven into them on explosion. These injuries were singularly fatal, as my earlier experience verified by the necessity of the removal of many such eyes in gunners in the west. Now a piece of cap on the instant of explosion is at a very high temperature, sufficiently so to destroy any germs that might adhere to it, as I have seen severe burns from such a fragment when lodging in the conjunctiva or skin, and it enters the eye therefore aseptic. The same may be said of fragments of steel which oftentimes enter the eye at white heat and are soon followed by the most intense reaction and panophthalmitis. Is the danger to the fellow eye, then due to the transmission through lymph channels of pyogenous germs? This is a matter still in the hands of the pathologist. In the *Archives of Ophthalmology*, January number for this year, Dr. Poplawska reports the examination of twelve panophthalimtic eyes for microbes and found colonies in all, but they were bacilli and not micrococci, the orthodox pus producers. Furthermore they were found, if the foreign body was lodged in the vitreous, developed immediately around it, and were not found in its track through iris, lens, or ciliary body. Nor have they been found in the sympathetically affected eye. But whether or not microbes are the agents by and through which sympathetic ophthalmitis is engendered in some cases, there are many in which they are not and cannot be.

Take the cases of sympathetic inflammation following ten, twenty, and even thirty years after the lodgment of a foreign body in an eye, and how can we explain them on the microbic theory? Certainly these ephemeral germs could not lie so long dormant to be suddenly awakened into activity. The other class of injuries which endanger the fellow eye are those in which some anterior portion of the uveal tract is involved. Any injury by which the iris or ciliary body or both, becomes entangled in a cicatrix and is dragged upon always contains the element of danger to the other eye. How soon or how late, or if ever, this may occur is a matter of conjecture. A cut or rupture in the sclero-corneal junction leaving a cicatrix is a well known menace to the opposite eye, and yet I have seen very ugly and extensive injuries in this region which had not been followed by any sympathetic trouble many years afterward, and yet a small perforating ulcer near the margin of the cornea, into which the iris is dragged, I have known to eventually destroy the opposite eye through sympathetic inflammation. Any entanglement of iris or ciliary body causing traction and more or less constant irritation, is one of the greatest dangers to the integrity of the fellow eye. As has already been said, the most important question to both patient and surgeon in the early stage of a traumatism is as to the possible risk to the fellow eye. How often have we seen a rupture of the globe with prolapse of the vitreous or iris, under careful treatment heal without further trouble? And who will always condemn such an eye in the beginning, especially if no severe reaction is present or imminent?

A case in point will serve to illustrate the responsibilities that devolve upon the surgeon just here.

A colored man came to me just after an accident to his right eye. It had received a blow from a piece of wood causing a transverse rupture in the cornea extending partly into the sclera at the outer side. The iris was entangled in the wound and the pupil was obliterated. Under antisepsis and bandage the wound healed in a few days. At the end of two weeks the eye was clear, there was no tenderness or pain, and he had good light perception in all parts of the field. I decided to make an iridectomy for the purpose of restoring vision, and requested him to call again soon to have it done. Two weeks later he called complaining of pain in the left eye. To my surprise I found a mild plastic iritis. The right eye was now injected, tender to the touch, and had nearly lost light perception. I at once enucleated it, and found a cyclitis starting in the scleral end of the cicatrix. The other eye was carefully treated, and responded at first to atropine, and all looked favorable for a while, but a change for the worse took place after a couple of weeks. and in spite of all treatment it went into an iridocyclitis and the eye was lost. Here was a most rapid and unexpected process. I had in my mind from the first sight of the case the probable danger sometime in the future to the fellow eye, but as there had been no reaction until the wound had thoroughly healed I certainly did not look for so sudden an outbreak of sympathetic ophthalmitis in the other eye. In contrast with this I might mention the case of J. C., a girl aged 11 years, who has a very conspicuous puckered cicatrix extending entirely across the right cornea, and about 6 or

7 millimeters into the sclera on the outer side, the scleral scar being particularly ugly and depressed with entangled ciliary processes in it, and the iris being adherent to the corneal scar in its greater extent. The eye had light perception, and never gave any special annoyance. I found increased tension, however, more marked sometimes than others. Her left eye has had defective vision for several years, since shortly after the accident, viz.: V = 4-200, but she had never complained of pain in it, or photophobia or any other symptom except inability to see well. Ophthalmoscopic examination discovered no abnormality in the eye whatever. As the right eye was useless, and the nature of the injury a dangerous one, I advised its removal. Her father refused, and so I requested that he allow me to make an iridectomy. This he granted, and I accordingly removed a section of the iris. There was no more increased tension after this. I could now examine the anterior of the eye with the ophthalmoscope and found aphakia, cyclitic membranes and floating opacities in the vitreous. The injury was caused by a piece of broken bottle, which, being hurled with considerable force, accidentally struck her on the right eye when she was seven years old. I am of opinion that, unless removed, this eye will eventually cause the loss of the other. What could be the cause of the lowered vision in the uninjured eye?

In another case with an eye affected similarly to this through sympathy, I had the pleasure of seeing vision return after removing the offending eye. There are features in the case sufficiently interesting to warrant reporting it.

S. T., aged 18, who entered the Ark. School for the Blind in Sept. 1890, was subjected to an injury of his left eye when four years old by the penetration of a fragment of steel while standing near an anvil on which two men were hammering a bar of iron. The eye first inflamed and then became quiet, but was blind. He attended school, and had but little trouble until about two years afterwards. At this time the injured eye became quite painful at times, and the other eye grew very weak, so much so that for three years before I saw him he was unable to pursue his studies. When I saw him in September, his condition was as follows: O. D. V. = counts fingers 12 feet, slight photophobia. Ophthalmoscopic examination negative. He stated that his vision had been about the same for three years past. O. S. globe tender to touch, and injected. Diagnosis, chronic panophthalmitis. I at once removed the inflamed eye. Soon after all photophobia disappeared from his right eye, but vision was no better. At the end of a week vision had slightly improved. In a month V. = 16-128, in two months it was 16-32, in four months it was 16-25. The eye had now grown strong and could endure constant work, and he was sent home. I later heard from him saying he had no further trouble in using his eye. In the injured eye was found a small fragment of steel encysted in the vitreous humor near the papilla. The eye was completely disorganized. What was the nature of the sympathetic trouble in this case? The most careful examination failed to reveal any lesion in the fundus of the right, and yet vision was reduced to counting fingers at 12 feet. Another strange feature in the case is the slow but complete return of vision after so long continued reduction of same.

In illustration of the tolerance of the eye to injuries and foreign bodies, I would mention a case I have already reported to this Section where a fragment of glass measuring more than a half inch square lay quiet in the ciliary region of an eye for ten years without any irritation or sympathetic trouble whatever, and the eye was only removed on suspicion of danger to the other eye on account of the extensive cicatricial formations and entanglements of the uveal tract in the sclero-corneal region, without suspecting the presence of the foreign body in the eye. While writing this article, my eye chanced to fall on the title of a paper in the May number of the *Ophthalmic Review*, by E. Treacher Collins, reporting nine eyes removed a very long time after having been entered by a foreign body. The shortest time in which trouble arose after the accident was 14 years, and the longest 28 years, and in three cases, 24, 14, and 28 years, respectively, the eyes were removed on suspicion of the presence of a foreign body without there being any pain or other trouble.

Not one of these cases would have passed through the hands of a modern ophthalmic surgeon shortly after the accident without his urgent advice to remove the eye with the offending body. While this would be sound philosophy, and place the surgeon on the safe side, yet we must recognize the element of uncertainty in every recent eye injury.

Only a few days since, a farmer refused to permit me to remove a very dangerous eye for him on the ground that he had known many one-eyed persons all his life, lost by accident, and had never heard any complaint from them. While I expect my self-wise patient to turn up in sorrow some day, I cannot be positive that he will, and he may for years to come boast of his judgment against mine. With all the uncertainty in one direction there is a certainty in another that outweighs all, and that is: While an injured eye may not affect the other sympathetically, there is in many cases, well established by clinical experience, *very great danger that it will*, and in case the eye is already totally or practically blind, it is a certain safeguard against such an accident to get rid of it, and the surgeon fails of his duty, who would weigh the trifle of looks or sentiment against the all-important question of sight.

THE SURGICAL TREATMENT OF TRACHOMA.

Read in the Section of Ophthalmology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY JOHN E. WEEKS, M.D.,
SURGEON NEW YORK EYE AND EAR INFIRMARY.

In the present stage of our knowledge of the treatment of trachoma, surgical procedures accompanied by proper local medication, afford the most efficient and most expeditious means of effecting a radical cure. Surgical interference is not a thing of recent date. Scarification more or less extensive, has been resorted to, for many years.

In the beginning of the present century, after the return of the French troops under Napoleon, from Egypt, this disease assumed such importance and was so widely spread throughout Europe that the minds of all medical men were active in the attempt to devise means for its cure. At one time scarification was quite widely employed apparently for the purpose of local depletion in cases where the hypertrophy of the conjunctiva was marked. From 1812 to 1813 bleeding was extensively practiced in England and Germany for the cure of this as well as of almost all other diseases. The amount of blood taken, running as high as sixty ounces in some cases. Some surgeons bleed from the veins, others from the arteries, each claiming especial advantages for his method. Local bleeding by the means of leeches was advised, eighty to a hundred leeches being employed in some cases. Moxies and blisters were also employed.

In 1811 Rust (London) advised excision of the affected conjuctiva; this was done by Elbe (Stuttgart) in 1839. In 1854 Pilz (Prag) practiced excision of the individual follicles. In 1859 Barilla, an Italian, devised an instrument consisting of a brush made of fine metal wire, which he used for the purpose of brushing out the trachoma follicles. Samelsohn (*Arch. f. Aug. u. Ohrenheilk*, Vol. III, 1873) employed a fine thermo-cautery for the destruction of individual granules, effecting a cure by repeated sittings. Reaction was controlled by cold compresses.

Fieuzal, Fröhlick and Hirschman have also practiced this method. Reich (*Klin. Mtbl. f. Aug.*, 1888, p. 56) has used the galvano-cautery, employing a fine pointed electrode. The thermo-cautery was used by H. Korn (*Berl. Klin. Woch.*, 1870, p. 201) in 1870 in the following manner: a glowing platinum rod was passed over the conjunctival surface much as the crystal of the sulphate of copper would be employed. The globe itself being protected by a Jaeger's plate. A superficial eschar was the result. A partial or complete cure was obtained after three or four sittings. The scars resulting were sometimes very annoying.

The systematic excision of the retro-tarsal fold was first practiced by Galezowski in 1874 since which time it has been employed with more or less modification, by many operators. Galezowski considers the operation to be applicable in all cases where trachoma granules are present in the retro-tarsal folds. His method is as follows: Ether is used in some but not all cases. The lid is everted and one blade of Galezowski's double pointed tooth-forceps is passed to the bottom of the cul-de-sac. The teeth of this blade are engaged in a fold of conjunctiva which is drawn downward and the forceps are closed over it. This gives the operator control of the fornix folds. With a pair of scissors the piece to be excised is marked out and carefully dissected from the underlying tissue. A piece of conjunctiva three to eight mm. wide and as long as the fornix folds is removed. No sutures are employed. The eye is washed with a mild antiseptic solution. A bandage applied and the patient sent into the ward.

Heisrath, Jacobson, Vossius and others excise a portion of the upper part of the tarsus, if the tarsal conjunctiva is involved, along with the fornix folds. Sattler uses sutures to close the wound in some cases. If the plica semilunaris is the seat of granulations, Sattler does not hesitate to excise it. Dr. Sueller (*Arch. f. Oph.*, V. XXXIV, p. 131) devised a clamp forceps which is a modification of Desmarre's forceps, with both blades fenestrated, which he employed for the purpose of engaging the fold of conjunctiva to be excised; after being caught in the forceps the fold was cut off by means of the scissors. He washes the conjunctival surface with sublimate 1-3000 after the operation and dusts iodoform on the denuded surface. A bandage is then applied. This dressing is renewed every day until the wound has healed; about eight days after the operation of excision of the fold, the operators agree in saying that in the majority of cases the remaining granulations gradually grow smaller and disappear. Relapses are infrequent.

Sattler (*Zeitschrift f. Heilk.*, Berl., 1891, p. 45) practices scooping out the contents of the follicles, employing for that purpose a sharp oval curette 2x4 mm. in size. The apex of the granule is scarified and the contents then removed with the curette. This is done in all parts of the conjunctiva, the loose folds being made taut by the use of some such instrument as the forceps of Heinheiser. This instrument (which is double pointed) is so constructed that the distance between the points can be increased after the conjunctiva has been seized. After the operation the conjunctival surface is washed with a solution of sublimate $\frac{1}{1000}$; this is repeated every day until recovery takes place. Swelling is reduced by the application of cold compresses. A number of sittings are necessary to effect a cure.

Electricity in the form of electrolysis has been advocated by G. Lindsay Johnson, of London (*Arch. of Oph.*, Vol. XIX, p. 264), to be used after the following manner: The patient is anæsthetized. The lid is everted over a horn spatula and held in position by a vulcanized double hook. The conjunctiva is then scarified with a three bladed "silonneur" adjusted to cut to the desired depth. The incisions are made parallel to each other and to the margin of the lid, over tarsal and fornix conjunctiva. After the bleeding has abated the grooves are traversed by a double bladed electrode which is connected with six Stoher's carbon and zinc cells. A yellowish, frothy mass exudes as a result of the electrolytic action. After cleansing, the conjunctival surface is dusted with calomel and is subsequently smeared with an ointment of hydronaphthol in vaseline $\frac{1}{800}$; the results are said to be very good.

Since Barelli (1859) devised his metal brush for removing the granules from the conjunctiva other appliances for the same purpose have been brought forward. Fodda (1870) caused an instrument to be constructed consisting of a metal plate set with numerous very fine teeth, arranged in rows, which he termed a "spinatore." Manelescu, of Bucharest, used a stiff, bristle tooth brush cut to $\frac{1}{4}$ in. in length for this purpose. Keyser, of Philadelphia, also employs it. (*Oph. Rec.*, 1891, p. 51.) This method is employed by Arnant (*Annal d'Oculistique*, Jan. and Feb., 1889) for the purpose of introducing a solution of sublimate, 1 to 120 or 1 to 100, into the trachomatous tissue merely and not for brushing out the the granules.

Expression as a surgical procedure in the treatment of trachoma is now widely practiced. I have been informed by an eye witness that Galezowski employed this procedure, in his clinic in 1874, and that he had a special forceps constructed for the purpose. Wolfe (*Diseases and Injuries of the Eye*, London, 1882, p. 51) advises scarifying with Desmare's scarificator and subsequently squeezing out the contents of the follicles with the thumb and fingers. One or two days later he applies a solution of tannin to be used by rubbing it on the conjunctival surface. At the meeting of the Illinois State Medical Society, 1889, Dr. Prince presented a ring forceps which he had devised in the treatment of trachoma. They were used as an adjuvant to other non-surgical methods. Dr. H. D. Noyes introduced a forceps of his own design shortly after those of Prince appeared and he has been followed by Knapp, Gruening and others. The mode of operating with Noyes' forceps is as follows: The patient is etherized, the lid everted and the loose folds of the conjunctiva caught up with the forceps; two pairs are used. A gentle stripping movement is persisted in, the folds being caught by one pair of forceps as the other pair passes off, until all of the trachoma granules have disappeared. The contents of the granules are pressed out and appear on the forceps as pulpy, reddish manes. Noyes' forceps are so constructed that the conjunctiva at the canthi and the semilunar fold can be rapidly reached, which is not the case with the roller or fenestrated forceps. The granules on the tarsal conjunctiva are reached by placing one blade on the tarsal conjunctiva and one in the retro-tarsal fold. The fenestrated forceps are used much in the same manner. Knapp's roller forceps are used, particularly in the treatment of trachoma follicles situated on the tarsus, by placing one blade on the conjunctival and one on the cutaneous surface. By compression the trachoma granules are crushed into the tissue of the tarsus, their contents not being removed. The after treatment as carried out by Noyes and Knapp is mildly antiseptic and astringent.

A method for the surgical treatment of trachoma has recently been developed by Darier, in Abadie's clinic in Paris (*Rec. d'Ophthal.*, Paris, 1890, p. 708) which consists in a combination of a number of methods previously in use. The affected conjunctiva is scarified and subsequently a strong solution of sublimate 1 to 500 is brushed into the tissue by means of a tooth brush. The method is termed "grattage." It has been used extensively in the clinics of Paris and to some extent in New York, with very good results. The surgical procedures employed for the treatment of trachoma have been briefly mentioned. We may now consider their relative value, but before doing so it would be well to consider the indication for treatment.

The outset of trachoma is usuall accompanied by redness of the conjunctiva, some hypertrophy of the membrane and considerable discharge. In certain cases the condition can with difficulty be differentiated from the ordinary conjunctival catarrh. The conjunctiva may assume a thickened velvety appearance, the granulations first becoming visible on subsidence of the swelling and intense hyperæmia. Usally more than one member of the family is affected with this form of trachoma and usually when it occurs in asylums or residental schools many of the inmates are apt to contract the disease. There is a class of cases occurring usually in children of from 5 to 14 years of age, in which on eversion of the lids a mass of pale spawn like granulations is thrown into view, embedded in the slightly hypertrophied conjunctiva. In these cases the annoyance experienced by the patient is slight. There is little secretion. This form of trachoma appears sporadically. It possesses but little of the contagious nature so pronounced in the form where the secretion is copious. The contagiousness of trachoma is probably in direct proportion to the amount of the secretion.

In this early stage, which might be termed the first stage of trachoma, the follicles are discrete. They consist of aggregations of lymph corpuscles, situated immediately beneath the epithelium, having a more or less marked fibro-vascular capsule and traversed by very fine trabeculæ of connective tissue fibers. As the disease progresses the follicles or granules coalesce. This occurs particularly in the upper third of the tarsal conjunctiva, but is not confined to this region.

The conjunctival surface becomes reduced in area, cicatricial patches and bands appear. From friction on the cornea superficial keratitis, deep ulcers and pannus result. This may be termed the second stage. The third stage is essentially one of atrophy, and shows rather the result of trachoma than trachoma itself. The surgical procedures necessary for the correction of the results of trachoma as found in the third stage, will not be considered in this paper, and consequently need no further mention.

The contagious nature of trachoma considered in connection with the facts elicited by Michel, Sattler and others in their bacteriological researches, furnishes very strong evidence of the microphytic origin of the disease. If we accept the above statement as facts, concerning the structure of trachomatous tissue and admit it to be of germ origin, we may easily formulate the general indications for treatment.

1. The obnoxious tissue should be removed if such a thing be possible, without producing too much deformity of the lid.

2. The destruction of the germs instrumental in the production of the disease, should any remain.

3. The after treatment should be so conducted that a smooth surface should result. Procedures that are purely mechanical may fulfill the first indication, but mechanical must be aided by therapeutical measures to fulfill the second and third general indications. It may be claimed that the plasma of the blood is sufficiently germicidal to destroy what trachoma germs may remain after mechanical means have been employed to remove trachomatous tissue. This may have a grain of truth in it, but the fact remains, that after purely mechanical means have been employed, recurrences of trachoma in the operated eyes is not uncommon. It is a fact recognized by all observant surgeons, and demonstrated by laboratory experimentations that bruised or crushed tissue forms a most favorable nidus for the development of microörganisms, therefore it is not only logical, but actually necessary that a germicide be employed after the surgical procedure to render the conditions for recovery most favorable. Recurrences should not occur, since their prevention is fully within our power.

In the first stage of trachoma the method by expression is by far the best to pursue. Since it does not imply loss of conjunctiva it is far better than excision. It is efficient and speedy, therefore better than the destruction of individual follicles by the cautery, removal with the curette, etc. Theoretically, and I believe it must prove so experimentally, it is better to remove the contents of the follicles than to crush them into the tissue. Because of this, I prefer to use Noye's forceps, regarding it as the best forceps made. In the employment of expression, I have found that the removal of the contents of the follicles is facilitated by a superficial scarification of the apices of the elevations, the incisions running parallel to the margin of the lids; I consequently scarify in these cases. After the expression, I am in the habit of introducing a germicide into the bruised tissue, using an ordinary toothbrush for this purpose loaded with a solution of sublimate 1-500 or 1-1000. After the treatment as above described, the patient may be treated as an out patient, but it is better to keep him in the wards of the hospital for a few days. In the latter case a compress bandage should be applied; after twenty-four hours the conjunctival sacs should be washed with a weak sublimate solution. If there is a tendency to puffiness of the lids, the bandage should be reapplied.

Swelling due to traumatism is much more easily controlled by a pressure bandage, and is more comfortable to the patient than are cold applications or medicinal applications of any sort. The tendency to swelling of the lids will have disappeared in thirty-six to forty-eight hours, when the bandage may be removed; but little reaction follows the operation.

To prevent the formation of adhesions between folds of the conjunctiva, it is well to sweep a probe through the conjunctival sacs at intervals of twenty-four hours for a few days after the operation. Mild antiseptic washes and the occasional application of a 1 per cent. solution of the nitrate of silver as recovery advances, will suffice to effect a complete cure without deformity.

This form of treatment which meets all the indications, has proven in my hands to be most satisfactory in the first stage of trachoma; in the second stage of trachoma it may be considerably improved upon. Sclerosed masses of trachomatous tissue will not be squeezed out, consequently if we would cure these patients we must employ other methods. The sclerosed tissue has been cut away by Sattler, and attempts have been made to brush it away by Manolescu. The form of treatment that in my hands has given greatest satisfaction in this class of cases, is that advised by Danier and Abadie. The method is known as "grattage." I have employed it now in quite a large number of cases, and have yet to see a patient on whom I have operated who has not been benefited. The greater number of cases have been virtually cured.

For the performance of the operation I have devised a scarificator and a forceps. The scarificator consists of a handle into which three movable blades are set. The blades are about one inch in length and are placed parallel to each other and about 1-16 of an inch apart. They may be removed for cleaning, at will. A guard to regulate the depths of the incision is supplied with the instrument. The forceps consist of a scissors handle with a catch. The blades are $\frac{2}{16}$ and $\frac{3}{16}$ of an inch wide, respectively. The opposing surfaces are ground in their long axes. The blades are of equal thickness from point to shank, and are $\frac{7}{8}$ of an inch in length. In use the narrow blade is placed on the conjunctival surface, the broad blade on the integument parallel to and at the margin of the lid. Eversion is performed by rolling the lid over the forceps.

The operation is briefly as follows: The patient is anæsthetized. If the palpebral fissure is shortened by cicatricial contraction a free canthotomy is made, the margin of the lid is now seized by the forceps and the lid is forcibly everted. This exposes and puts on the stretch the whole conjunctival surface. The trachomatous tissue is then scarified to about $\frac{2}{3}$ of its depth, the incisions running parallel to the margin of the lid. The surface is then rubbed over with the back of a scalpel or the conjunctiva is manipulated with the trachoma forceps for the removal of the movable trachomatous tissue; after this the conjunctiva is brushed, quite vigorously, with an ordinary tooth brush which carries a solution of the bi-chloride by means of mercury $\frac{1}{500}$. After thoroughly introducing the bi-chloride by means of the brush the canthotomy is converted into a canthoplasty; if permanent enlargement of the palpebral fissure is desired the surface of the conjunctiva is cleansed and a compress bandage applied. The previous remarks regarding traumatic ordena apply here. Severe as the operations may appear the reaction is usually very slight. The after treatment is very important. It consists in preventing adhesions between folds of conjunctiva by occasionally sweeping a probe through the conjunctival sacs and by the application of antiseptic and astringent solutions as required. It is customary to apply a solution of sublimate $\frac{1}{500}$ to the conjunctival surface every twenty-four hours for from three to eight days after the operation. Bathing with a solution of boric acid 3 per cent. two or three times daily and the application of astringents as required. The treatment may produce the result desired in three weeks—it may require three months, however. A satisfactory result is the reward in almost every case which cannot be hoped for in other cases by other methods of treatment. Nellie Lynes, N. Y., aged 28 years, came to my office on March 19, 1892. She had suffered from trachoma of the conjunctiva of the left eye for three years. The patient has been under the care of Dr. D. B. St. John Roosa for about two years having been an inmate of the Manhattan Eye & Ear Hospital for three weeks. About two months before seeing me she had been operated upon by the roller forceps by Dr. Herman Knapp. When first seen the conjunctiva was rough, there were distinct trachoma follicles in the tarsal conjunctiva and a few in the retro-tarsal folds. There was superficial keratitis and vascular pannus with narrowing of the palpebral fissure, intense photophobia and profuse lachrymation. I advised the treatment described above. The patient was admitted to the New York Eye & Ear Infirmary on my service and the operation was performed on March 22. At the end of two weeks the patient was discharged with the lids much improved; there was still some roughness.

The pannus and superficial keratitis were much improved. She has since been treated as an out patient at my office, coming twice or three times a week. When seen last, June 2d, the lids were smooth, the cornea free from ulceration, no photophobia. Patient experiences no discomfort. She has resumed her position and is virtually cured.

The presence of corneal ulcers or pannus was marked; using the galvano-cautery for the purpose the pannus was favorably affected by this procedure but was not entirely done away with.

I wish to emphasize the necessity of careful and persistent after treatment; without it failures will result and the operation will not meet with the favor that it deserves.

Experience has led me to the following conclusions, viz: *a.* In the first stage of trachoma the most efficient mode of surgical interference is that of expression combined with superficial scarification and the introduction of a germicide by the use of a brush. *b.* In the second stage, where surgical interference is advisable the treatment known as "grattage" combined with expression in some cases. Canthotomy or canthoplasty if necessary, gives the most satisfactory results. *c.* The operations as above advised convert a contagious into a non-contagious condition and the patient may be admitted to wards for ordinary surgical cases, without fear of infection.[1]

Discussion.

Dr. L. H. Taylor, Wilkesbarre:—During the past two years I have had considerable experience with the operation of expression. I happened to be in New York three years ago, and saw a patient operated on by Dr. Noyes. Immediately afterwards I secured a pair of his forceps, and soon afterward I operated on a patient whom I had been treating for more than six months with very little benefit. I recently had occasion to see this patient again. The operation was done two years ago, when the patient was 16 years of age. She has since remained entirely well. Since that time I have operated on quite a number of patients, to a limited extent with cocaine, but this is very painful, and I think that the patient should be etherized. I think, in regard to what has been said, that it is possibly not so much the method as the thoroughness with which it is done, and the kind of a case upon which we operate. Many of the cases of hard, dry trachoma are, in my judgment, not suited for the operation. It is rather cases of the follicular type in which the soft matter can be expressed. I have seen considerable reaction in some cases, but nothing serious. The after-treatment has been kept up for some time. This has consisted in the use of astringent and antiseptic applications.

---

[1] For some of the data relating to the history of the surgical treatment of trachoma, I am indebted to Sattler, Zeitschrift f. Heil., Berl., '91, p. 45. For record of cases and further discussion see Weeks, N. Y. Medical Journal, October 24, 1891.

Dr. H. V. Würdemann, Milwaukee:—In the State of Wisconsin we have a large foreign element, and hence our surgeons seem to see an undue proportion of cases of trachoma. Hardly a week passes in my private practice without an operation for trachoma, usually by expression or by the method of Sattler, and occasionally by the use of the fine galvano-cautery point. After that I use sublimate and other medicinal treatment, massage by boric acid, etc. After this, if necessary, I use blue stone. I do not consider the case fully cured until it has been under observation for six months; that is, in follicular trachoma. In lymphatic trachoma we frequently are obliged to operate several times, and I don't consider it advisable to promise but one operation, or permanent cure without months of subsequent treatment. After surgical treatment we do not see so much scar formation as after cases treated entirely by blue stone.

Dr. F. C. Hotz, Chicago:—It is pleasing for one who has advocated for many years the mechanical treatment of trachoma, to see that the method has gained many friends. Six years ago, I recommended in the *Archives of Ophthalmology* the method of expelling the trachoma follicles by pressure, and at that time, as far as I could learn by researches, this mechanical treatment had been practiced by very few oculists.

The method to be employed is a matter for individual choice. It makes little difference what method is adopted, provided it is done gently and thoroughly. I believe in the principle always to use the simplest means for accomplishing your purpose. I therefore do not employ specially constructed instruments if I can achieve the same thing as well with my fingers, and the evacuation of trachoma bodies in the upper lid can thoroughly and quickly be accomplished by pressure with the fingers properly applied. I turn the lid and hold it everted with the forefinger of one hand, and run the thumb or the forefinger of the other hand up under the lid to the end of the retrotarsal fold. The lid is thus placed between two fingers, and when these now are gently pressing toward each other, and at the same time are gliding down toward the lower edge of the everted lid, any follicles caught between this finger-press are thoroughly squeezed out.

That is the simplest method, and can be done at any time, because you always have your instruments with you. Of course it is difficult in this way to reach follicles near the angles of the lids. To reach these recesses, forceps of one kind or another are very convenient. I am not particular what kind you employ. I have adopted a pair of forceps after the pattern of the old-fashioned long curved iris forceps, and they answer the purpose better than any ring or roller forceps. In the lower lid, where we often have a long fold of infiltration, we can remove the contents readily with the forceps. Thoroughness and gentleness are most important, and it is surprising how little reaction is seen after the procedure. That one application, no matter by which method, will be sufficient, no one will claim; and treatment of the lid for some time is always necessary to insure permanent results. Of all the operative treatment, the squeezing method is, in my opinion, the best and the gentlest. Scrubbing the eye with a tooth brush, I think is too barbarous and brutal a procedure to be admitted. The excision of a portion of the conjunctiva is a very quick way of getting rid of the diseased conjunctiva, but the treatment is worse than the disease. It resembles the attempt to relieve a person permanently of a corn by amputating the toe; for if you remove the conjunctiva there is no soil left for the trachoma to grow in.

The mechanical treatment avoids the shrinkage of the conjunctiva and the destruction of the membrane by atrophy, and it saves to its full extent the retrotarsal fold, which in the movements of the eyeball plays an important *rôle*. When shrinkage takes place, the eye is embarrassed in its movements, and mechanical irritation is set up by the shortness of the fold, which does not allow the eyeball sufficient freedom of motion.

Dr. H. Knapp, New York:—I have treated a good many cases in this way, and have used different instruments. I have used the instrument of Dr. Prince, and also that of Dr. Noyes. I could succeed with either, but not without a good deal of laceration of the conjunctiva. I therefore devised the roller forceps, and since then, the more I have used it the better satisfied I have been with it. Dr. Weeks says that the follicles are crushed and not expressed. All the material which is held between the rollers comes out in globules or as a viscid fluid. That is just what insures success. The granules in the inferior as well as those in the superior retrotarsal fold are readily pressed out. Be the lids never so studded, the follicles can mostly be removed cleanly and the case cured in one sitting. I can prove this by dozens of cases. The operation requires ten minutes or more. All the granules come out, and there is nothing left but completely clean mucous membrane, over which the roller passes without resistance. When this condition in follicular trachoma is reached, we may be sure that nine cases out of ten are cured, and we need use no antiseptic. This method causes less traumatism, and can be done with greater thoroughness, than any other that I have seen. There is no method that is free from relapses. If these relapses come under treatment early, a few touchings with blue stone mostly afford prompt relief. A permanent cure is more likely to be secured when the squeezing is followed by four, five or six weeks of sulphate of copper treatment. A perfectly healthy mucous membrane, with very little cicatrization, is obtained. That all cases are cured without relapse, I do not pretend. Five or six cases out of 250 have come back to me with relapse, and I had to repeat the squeezing. These were very bad cases, but all cured by the second operation.

Concerning antiseptics, I am not sure that our bacteriological researches in regard to trachoma are perfect. They are not sufficient to demonstrate that trachoma in all cases is a bacterial or contagious disease. There are a number of cases where there is not a particle of irritation, and where the patient is not aware of the trouble until we turn the lids and find the retrotarsal folds studded with granules. There has never been any pain, heat, or discharge. The granules are like lymph follicles. It is not considered as demonstrated that any particular or specific microbe is the cause of trachoma.

On the other hand, we are well aware that trachoma is the consequence, or follows in the wake of inflammatory diseases of the conjunctiva. The contagiousness of such cases is unquestioned.

As regards the therapeutic effect of the mechanical treatment, and especially the method of squeezing out the trachomatous material, I can say that it has proved a great blessing in my practice. It shortens the treatment very much, and in a number of cases it effects a cure in one sitting without other treatment. Next to cataract, I think that trachoma is the most important of the diseases of the eye. In regard to diffuse and cicatricial trachoma, my results have not been satisfactory.

Dr. J. E. Weeks, New York:—In regard to the action of the roller forceps, the construction of the roller and its application to the surface of the conjunctiva, certainly implies that the tissues between the rollers must be crushed, and where there is sufficient tissue left between the rollers to permit of the retention of the subconjunctival tissue, a greater amount of trachomatous material must remain than where simple squeezing is employed. I have seen more recurrences after the use of the roller forceps than after the use of the forceps devised by Dr Noyes, and I think that the mechanical principles involved in the construction of the two instruments are certainly in favor of the forceps of Dr. Noyes.

In regard to the use of antiseptics, while I have not maintained that trachoma has been *proven* to be due to germs, I have suggested that the researches that have been made, and the history of the disease, are such that we may consider it more logically to be of microphytic origin than due to any other cause. We have here an affection which, in the majority of cases, has seemed to me to be contagious. We find that where trachoma occurs in one member of a family, it usually affects a number. Where it occurs in residential schools a number of scholars, as a rule, are attacked. If this does not point to contagion I do not know what does.

Dr. Knapp:—How about trachoma confined to one eye?

Dr. Weeks:—We have gonorrhœal conjunctivitis, a disease known to be of microphytic origin and also contagious, confined to one eye—this is also, not infrequently, the case in epidemic catarrhal conjunctivitis. Trachoma confined to one eye is exceptional, and does not afford the slightest evidence against its contagious nature. If the disease is contagious, it is logical to use an antiseptic (I have been informed that Dr. Knapp himself uses an antiseptic in the treatment of trachoma). It seems to me that in this way we may prevent recurrences that otherwise would take place.

I have seen a good deal of the treatment with blue stone, and can remember only a few cases where a cure was effected. Relapses are the rule, and the treatment of the relapse by a few applications of blue stone does not suffice to cure it. It is exceptional to find a radical cure follow the use of blue stone. Experiments with a pure culture of the staphylococcus aureus made by myself in Knapp's laboratory, demonstrated that blue stone is not a germicide. It is therefore a simple irritant, and increases the vascularity of the conjunctiva. Even if it can be shown that "dozens of cases" are cured by expression alone without an antiseptic or after-treatment, that is no proof, and is no argument against the use of a germicide. If only a few relapses occur, a germicide should be employed to endeavor to prevent all recurrences.

CLINICAL HISTORY OF A CASE OF SUCCESSFUL EXTRACTION OF A PIECE OF STEEL FROM AN IRIS AND LENS BY AN IRIDECTOMY, WITH SUBSEQUENT ABSORPTION OF THE LENS AND RECOVERY OF NORMAL VISION.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CHARLES A. OLIVER, M.D.,
ATTENDING SURGEON TO WILLS' EYE HOSPITAL; OPHTHALMIC SURGEON TO THE PRESBYTERIAN HOSPITAL, ETC., PHILADELPHIA.

On the second day of March, 1891, H. M., æt. 29 years, a blacksmith, came to Wills' Eye Hospital, complaining that his right eye had become inflamed from the supposed lodgment of some foreign substance in the cornea one day previously. Attempts at extraction had made the eye very painful, which was relieved by the use of a weak infusion of tea leaves. Two years previously, the same eye had been struck by a piece of steel measuring roughly about 4 millimetres square, the foreign body not penetrating the eye, though leaving the organ irritated for several days' time. Vision was in no way subsequently disturbed, and the organ had never become troublesome up to the time of the second accident.

At the time of the first examination, a small mass of foreign substance was found imbedded in the upper inner quadrant of the cornea, about 3 millimetres above the horizontal meridian, and in an almost identical position in the underlying iris, there was a round black bead about the size of the head of a small pin, from the upper part of which could be seen, by strong oblique illumination, a line of metallic-like lustre. A faint deposit of precipitates on the membrane of Descemet, with slight pericorneal injection, existed, though there was no evidence of any ciliary tenderness. Vision with this eye had fallen to slightly less than one-eighth (5-40?), and the accommodative range was limited to the reading of type 0.75 D. from 13 to 30 centimetres. Through the undilated pupil, the eyeground could be fairly seen, it appearing healthy. No abnormality could be seen in the left eye, its vision being one and one-half (5-7½), and the accommodative range extending from 13 to 36 centimetres for 0.50 D. type.

The foreign substance was removed from the cornea, and upon consultation with Dr. Wm. F. Norris, an immediate iridectomy, including the piece of supposed metal, was advised; the latter procedure, however, the patient refused to accept. Upon this decision, a soothing collyrium of boric acid and a Liebreich bandage were ordered, with a request that he should report in the morning.

Upon the following day the patient returned to the hospital, stating to the resident surgeon, Dr. Zimmerman, that an exacerbation of pain in the eye during the night, had decided his willingness to return for operation. He was immediately put to bed, bowels were purged, eyes bathed freely, and he was kept quiet until the next clinic day (March 4), when upon reëxamination, the anterior chamber was found somewhat shallow, and the lens was slightly swollen and becoming opaque in the position of the situation of the foreign body. At this time, the iris tissue in the vicinity of the traumatism was noted as muddy in appearance, with the formation of a synechia at the upper pupillary edge, the ciliary region being slightly tender to the touch. In spite of these inflammatory conditions, a narrow incision with an angular keratome was made at a position in the cornea just inside of the limbus, corresponding with that of the foreign body, and an iris forceps passed in and the object (a flat piece of steel of about 1 millimetre in diameter), with the surrounding bruised and inflamed iris tissue, grasped, brought out and excised—making a clean iridectomy. The lens area exposed to view showed the point of the original wounding of the capsule, with the situation of the greatest amount of swelling and opacity. Atropine and a light pressure bandage were applied, and the internal administration of small tri-daily doses of calomel, with rest in bed, was enjoined. In two days' time, the wound in the cornea had healed, the inflammatory symptoms had greatly subsided, and the lens matter had begun to rapidly absorb, until on the 18th of the month, there was but one plug of lens material to be seen, this being situated in the lower portion of the anterior chamber. Eleven days later, the remaining lens mass had disappeared, the eye was quiet, and vision could be brought to almost normal by the use of a + S. 11 D. lens.

At the present time, about fifteen months after the accident, there is a perfectly quiet eye, with a narrow coloboma up and in; an eye which, in spite of a few fine linear folds of capsule at the lower inner border of the pupil, which can be barely recognized during moderate pupillary dilatation, and a faint concentric ring of lens and capsular débris, which can only be seen at the periphery of the coloboma, possesses normal acuity of both central and excentric vision, the patient possessing an acuity of 5-5 with + S. 11. D. ⊃ + C. 0.50 D. ax. 100°, and reading many words of type 0.25. D. fluently at 8 inches distance with an additional convex lens of 4 diopters strength.

The case is interesting upon account of the immediate curative effects of an iridectomy which removed an offending substance and its bed of bruised and inflamed iris tissue, thus allowing a free, rapid swelling and disintegration of lens matter to uninterruptedly take place during a watchful and careful after-treatment; this immediate happy result being supplemented by a subsequent restoration of vision to full acuity, with but little necessary correction of astigmatism, in a comfortable and unirritated organ.

The Bicycle in Medicine.—Dr. W. H. Burr, of Wilmington, in *Merck's Bulletin*, observes concerning the treatment of tuberculosis that it is irrational to fill the patient with drugs, if no attempt is made to change the environment in which the disease was contracted. His system should be "flooded with oxygen" as a prime requisite to a reformed metabolism—while at the same time the excretory organs are not overlooked. "The bicycle," says Dr. Brown, "in my opinion is one of the most advantageous means of administering oxygen. The bicycle will digest more fat meat and starchy vegetables than any other means of exercise known." The late Dr. Frank H. Hamilton was fond of saying that "the best thing for the insides of a man is the outside of a horse," but he was of that generation, now nearly passed away, that was unacquainted with the wheel in its newer forms and those that are best adapted to the open air occupation of invalids. Thousands of persons can have bicycles to whom the living steed is out of the question. And the proprietorship of a horse is not an unalloyed privilege, since too much exercise may at times be unavoidable through considerations affecting the servant-animal, but the bicycle can be stopped and made to rest at the will of its owner. Dr. Burr concludes his observations by saying: "The latest theory in the treatment of tuberculosis is rest. I prefer to say: Action with rest—as the unpleasant necessary concomitant—but which should be gradually, steadily and progressively abridged." Mr. Gladstone is an ardent admirer of this most rational means of physical betterment. He is reported to have said recently, in an interview: "I can only emphasize the fact that I consider that physically, morally and socially, the benefits that cycling confers on the men of the present day are almost unbounded."

Colored Morphine.—It has been proposed by a German physician that morphine be always stained a bright red with aniline, in order to diminish as far as possible mistakes in compounding.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES . . . . 10 CENTS.
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 3, 1892.

THE TURKISH BATH.

DAVID URQUHART, an enthusiastic Englishman, was the foremost promoter of the hot air bath, named by him the Turkish bath, which is daily challenging the attention of the medical man. Its increasing popularity among the laity calls for thoughtful action by the profession. If it is to be permanently identified with the life of our people there will necessarily be much in it of great practical interest to the scientific physician. Hot air as a therapeutic measure is older than the time of HIPPOCRATES, who identified himself with its use. During the prosperous times of the Roman Empire it became one of the most popular institutions of the day. The many ruins now standing throughout what were but provinces of Rome, attest its extensive employment at that time.

No new theory is propounded, on the contrary, this is what has been known, though imperfectly practiced, for centuries. Air and water and temperature are the most salutary and unfailing agents for the correction or alleviation of the numerous derangements to which life is exposed.

In the hands of its modern advocates the Turkish bath has met with varying fortunes, according to the skill or merit of its promoters, and it is most desirable that the scientific mind should rescue it from whatever pertains to charlatanry. Its use as a therapeutic measure naturally comes within the province of the medical profession, and if there follows even a fraction of the benefit claimed by its enthusiastic advocates, the community will have occasion to be thankful.

Its action in rheumatism and some of the neuroses, as well as blood poisoning, has been marked by many successes. But the larger field for this bath will probably come in the line of preventive medicine. It does prove of service as a means of rest to those who are suffering from the every day pressure of overwork. There is little doubt that our people will gradually become educated to the legitimate use of this bath, and that it will ultimately be largely adopted by them as a habit. It will supply a much needed want, by increasing our sanitary resources, helping to lift all to a higher plane of health, and the physician to a higher standard of work. A most desirable and convincing method of promptly testing this would be by placing a well equipped Turkish bath, in charge of one conversant with it, in some of our asylums and hospitals. It is a lamentable fact that bathing facilities in these institutions are as a rule of the rudest and most undesirable kind.

It is well to guard against any immature conclusions. At the same time, those who have experienced the feeling of vigor and elasticity arising from the use of this bath will be inclined to pardon the enthusiasm of its votaries. Opportunity, tests, and time will surely reveal all its lasting virtues, and it is always wise to range ourselves on the side of cleanliness and purity. It was DR. ANDREW COMBE who said, "We ought to extend the hand of welcome to every man who is able to correct an established error, or add a new truth to the existing store; and much more so, if the offered contribution should be of that new and important principle capable, if true, of modifying and improving the whole field of medical practice."

There is a moral obligation resting on all who have intelligence and opportunity, to become acquainted with the laws of health, and live in obedience to them, and also to gain a knowledge of the simple and natural agencies by which deviations from the normal standard can be corrected. When once this knowledge becomes general, there will be a vastly smaller field for any form of quackery, and the too general use of patent medicines will be dispensed with. None are better qualified than medical men to lead in such a reform.

NON-NARCOTIC TREATMENT OF DELIRIUM TREMENS.

DR. NORMAN KERR made some remarks at the Nottingham meeting of the British Medical Association, in favor of the use of the liquor ammoniæ acetatis, to the exclusion of all narcotics, in delirium tremens. He stated that he now relied, even in the graver forms of the trouble, on drachm doses of that remedy, given every hour. Milk, beef juice, broth and coffee are frequently administered. In the case of a publican, in his third seizure, rendered especially serious by an intercurrent eplosion of epilepsy, this treatment resulted in sleep at the end of seventy hours. This sleep lasted four hours, after which there was a period of wakefulness for four hours more, and then a long sleep of twenty hours. The subsequent recovery was more rapid than from his second attack, which had been treated with opium and bromides: in that seizure even after a forced narcotic sleep the man was so violent that four men were needed to control him, and in order to save his life he was put in the padded room of the nearest workhouse.

These two attack, says DR. KERR, as quoted in the *Medical Press and Circular* for August 10, were typical examples of the graver form of delirium from alcoholic saturation. The compared results of the two different plans of treatment bespeak a reliance on a safe sudorific like the liquor ammoniæ acetatis and suitable nourishment, as best fulfilling the conditions of cure; the main point being, in his opinion, the avoidance of all alcoholic stimulants and all narcotics. "The best hope of cure lay in natural exhaustion inducing sound refreshing sleep." While this state persists the *vis medicatrix naturæ* is given a fair field to accelerate the elimination of the accumulated alcohol.

"THE BRABAZON WORK."

By this name is understood to be indicated those plans of employing the insane and other non-valid dependents of the State. The *Charities' Record* contains some of the newest facts regarding this means of adding to the welfare of the inmates of poorhouses—not the able-bodied, but the infirm. Some time ago we published in these columns an account of the "Brabazon Employment Scheme" in vogue in some of the English workhouses, and later a letter from a lady in Philadelphia telling of what is being done at the Blockley Asylum for the employment of the insane. A committee of the Central Association has been formed to take up this work in the State and already something has been done. The inmates of the epileptic pavilion on Blackwell's Island, New York City, have been instructed in needle-work of various kinds and under this instruction have made a number of articles from materials furnished them, whereas heretofore their time has been almost entirely spent in idleness. The Richmond County Committee, which is doing so much intelligent and helpful work, sends the following report: "The Brabazon Work has been started and has given occupation and pleasure to several of the inmates; floor-cloths and mats have been made and sold, a small percentage on each article being paid to the inmate who worked it, and she gives it to the matron to spend for her. The rest goes toward a fund for buying material."

The *Record* then quotes the following paragraphs, from a recent article, which might find corroboration in the experience of hundreds of physicians: "The fact of doing work which has a value, however slight, is a fact full of high suggestion to our worker. To have learned to sew the plainest seam well, or to thread a needle; to have learned to drive a saw or swing an axe effectively and with economy of strength, or to pile a range of wood intelligently, is to many a cramped, debased life not less than is the acquisition of the technic of his profession to the sculptor or the musician.

"With the discipline of work rightly directed, comes 'feeling for good work,' the perception of order and form and beauty, the quickening of moral sense, the turning of desire toward that which is above. From the lowest detail of handwork an upward way opens and invites the soul to rise in it."

These results of work, well performed, are true to the point of being a truism—they may be the physiological effects of the tenth sense, "the sense for good work."

CHOLERA.

Since our last issue cholera has spread with even more than usual rapidity. In Europe it is no longer confined to the seaports of Havre, Hamburg and St. Petersburg, but is also in Berlin, Antwerp, Liverpool, London and at other points in England.

In Great Britain but little dependence seems to be placed in quarantine measures for the effectual stoppage of the introduction of the disease. The sanitary officials relying more upon a good sanitary condition of the cities and towns, hoping thereby, to ameliorate the force of the epidemic, which seemed certain to evade all quarantine barriers that might be erected against its invasion.

In our own country the National Government has established strict quarantine stations at all ports of entry, and has done everything possible in that way, except to suspend immigration. This has been urged by the Michigan State Board of Health, and although the measure is extreme, the existing conditions are such as to warrant its adoption. There is no doubt as to the supreme value of quarantine measures, but to be effectual against the introduction of so infectious a disease as cholera, these measures must approach conditions of complete isolation.

State, city and village health boards are all active in bringing about a most desirable condition of public cleanliness.

Native Americans are generally pretty well informed in regard to correct rules of diet and living, but we have an enormous population of recently arrived immigrants, many of whom are of the lowest grade of intelligence. All their lives accustomed to the most unsavory conditions, ignorant of the common laws of health and disease, they naturally congregate in the large cities, and crowd into the vilest of tenements, where they constitute ready receptacles for any infectious disease.

Our country can well afford to suspend immigration for several months. If a cholera epidemic will show to our National Congress that for altogether too long a period this country has been an indiscriminate and dangerous dumping ground for the slums of European and Asiatic countries, it will not be an unmixed evil.

There is a brotherhood of man which says we are our brother's keeper, at the same time in the brotherhood of Nations it may become our duty to instruct Kings, Emperors and Princes that it is their duty to provide for those of their own households and dominion, and to do it in their own country.

Medical Educational Requirements in the United States.—Since the adoption, by a majority of the colleges in the United States, of a minimum standard of requirement embracing three courses of graded instruction, of not less than six months each, and a standard of preliminary educational training of all medical students, the question of recognition of graduates of those schools which do not observe this standard, has been practically settled by the American Medical Association. At Detroit, on Thursday morning, June 9, 1892, a preamble setting forth the requirements of the Association of American Medical Colleges, and a resolution demanding of all the colleges in the United States the adoption and observance of a standard which shall not fall below the minimum requirements of the College Association, were unanimously adopted, and the Secretary directed to forward a certified copy to the Faculties of all the colleges, and to each medical journal.

It is clearly apparent from this action, and from the recent action of many of the State Societies, that graduates, after July 1, 1892, from colleges which disregard this mandatory action of the American Medical Association, cannot be recognized as regular physicians, inasmuch as they have not passed through the required course of educational training. Societies, therefore, otherwise entitled to representation in the American Medical Association cannot, if they admit such persons to membership, be longer entitled to send delegates to the National body. Colleges disobeying the resolutions of the American Medical Association clearly put themselves beyond recognition, and it is likely that the members of their Faculties will be refused the right to register in the National body, either as permanent members or delegates.

Revision of the Code of Ethics.—For sometime it has seemed desirable to reorganize the National Association on a plan similar to that of our general government, so that every State and County Society in the United States with their individual members would become component parts of the great central organization and brought into closer relations with and more earnest support of it than seems to be attained by the plan now in vogue.

If some feasible means be suggested whereby this will be accomplished, there can be but little doubt of the more rapid growth and greater strength of the Association. The suggestion which the Journal puts forth now is that the Association be so reorganized as to bear the same relation to the State Societies and their subordinate county or local Societies that the national government bears to the several States that compose the Union, with the proviso that each State shall be in its medical organization as it is politically, sovereign, and have the right to make its own laws and code of ethics to suit the varied conditions of the medical profession as they exist in each of the States.

In a country so vast and varied as ours, with its dissimilarity of medical population as much as in other respects, it may not be possible to promulgate a general code that shall be applicable in all the States.

The State of New York, with its cosmopolitan population from all the quarters of the globe, its immense hospitals, great schools, private sanitariums, dispensaries and clinics, with medical laws and medical men as varied, may not find it possible to conform to a law that is applicable in Arkansas, where there are no large cities, few specialists, one medical school, no private sanitariums, etc., etc.; without a State Board of Health and having one of the vilest medical laws *that ever disgraced the statute book of a State.*

Or, maybe, Alabama, with the whole medical act administered through the machinery of her State Society, cannot find it consistent to say that her *regular* physicians shall not consult with those who, though technically *irregular*, have nevertheless been by the agents of her State Society licensed to practice medicine. In Alabama it would be embarrassing to a member of a board of examiners to have to refuse to consult with one whose license bore his signature attesting the ability of its holder to practice medicine.

There are no two States in the Union having the same medical laws, and the same conditions of the medical profession do not exist in any two of them. Then why not let each State Medical Society adopt its own organic law and code of ethics, which shall be subject to the approval or rejection of the American Medical Association just as each State is admitted to the Union by an act of Congress enabling it to call a convention and adopt a Constitution which shall conform to the requirements of the Constitution of the United States.—*Jour. Ark. Med. Society.*

ASIATIC CHOLERA IN EUROPE AND AMERICA.

We are indebted to the Tennessee *State Board of Health Bulletin* for the following concise account of the various epidemics of Asiatic cholera and their course:

In view of the extensive and steady spread of cholera in the Russian Empire, and of the great uneasiness manifested both in Europe and America as to its becoming, as in former years, a pan-epidemic, we give in this *Bulletin* memoranda connected with its past history. All sections of Tennessee have been visited by this disease at different dates from 1833 to 1873, inclusive. By observation or by tradition all our people are more or less familiar with it. In a subsequent number we hope to give an outline of its history in Tennessee.

One broad fact appears in lucid brightness. The mystery that once enveloped the plague no longer exists. It need not get into the Union or into Tennessee. If from culpable oversight, carelessness or penuriousness it does get over the lines, it need not spread. Isolation, sanitation, disinfection, humane care are the safeguards. Money will secure all these. The public can well afford to furnish all that is wanted for this purpose, since the return is truly a hundred fold.

1629.—Bontius, a Dutch physician at Batavia, described the disease and first made it known to the medical profession in Europe.

1817.—It raged with great violence at Jessore, from whence it spread, not very swiftly, but with great certainty, in all directions.

1818.—By August it had reached Bombay. Thence it traveled through Arabia, Persia, Mesopotamia, Syria, etc., on its westward course, and, continuing to extend itself eastwardly from its place of origin. invaded the Burmese Empire, Siam, Java, China, and other populous countries of that portion of the earth.

1823.—It appeared at Orenburg and Astrachan, on the eastern frontier of Russia.

1828.—Remained here until this year, when it increased in violence, attacking a tenth of the inhabitants of the province of Orenburg, proving fatal to a fourth of those affected.

1830.—Reappeared at Astrachan. In less than a month 4,000 persons died of it in that city, and over 21,000 in the province.

1831, June 26.—Appeared at St. Petersburg, having ascended the Volga and destroyed thousands in Moscow. From Astrachan it also diverged along the northern coast of the Black Sea, and thence spread into Austria, Poland, Prussia and Northern Germany.

1831.—In August it was conveyed to Cairo by a caravan from Mecca. Over 15,000 died of it.

1831, October 26 —It appeared for the first time in England at Sunderland, from whence it spread slowly through the northern part of England and into Scotland.

1832, February 14 —It broke out in London.

1832, June 8.—The cholera broke out at Quebec, its first appearance in America. Two days afterward it was in Montreal.

1832, June 24.—New York was attacked. From thence it spread to Albany, Philadelphia, Cincinnati, New Orleans, etc. In New York it reached its height on the 21st of July.

1836.—It lingered in the United States for four years, and then entirely ceased. This first epidemic of cholera cost Great Britain and Ireland 40,000 lives out of 116,000 persons attacked. In the cities of Quebec, Montreal, New York and Philadelphia, embracing then about 450,000 inhabitants, there were over 18,000 cases and 8,000 deaths. In India it remained endemic. Other Asiatic countries also suffered severely.

1846.—It appeared at Kurrachee early this year, near the mouth of the Indus, with terrific violence. Thence to Teheran, capital of Persia. Here its severity was such that 300 perished daily for several weeks in a population of not more than 60,000.

1847 and 1848.—Cholera ravaged parts of Russia and Turkey, having entered Eurrpe by almost the identical route as before. It traveled. however, with much greater rapidity.

1848.—In the autumn it appeared in France and Great Britain, revisiting during the next eight months with almost unerring certainty every place in which it had appeared in 1832-33, and seeking out the same filthy lanes and undrained sections of the cities where it had then committed its greatest ravages. It was even more malignant than in its previous visit. In England and Wales it carried off 53,293 persons.

1848, December 4.—The ship New York, from Havre, arrived at Staten Island with cholera among her passengers.

1849.—It occurred in New York. The whole number of cases reported outside the hospitals in fifty-two days were 2,631, of which 915 died. Also in New Orleans, and spread over the greater part of the Eastern and Western States.

1850.—In New Orleans deaths from cholera May to December, inclusive, 824. Cases occurred as late as February 15, 1851.

1850.—At Cincinnati, from June 1 to August 15, 1,400 deaths from cholera. At Columbus, Ohio, from the 24th of July to August 25, 195 deaths from cholera—a great mortality for the population.

1851.—A second visitation at Cincinnati. Some 200 deaths, mainly in July.

1851.—From April to August, inclusive, 766 deaths from cholera in St. Louis. Total for the year, 847.

1852, May, June and July.—Numerous cases in Cincinnati.

1852.—Total deaths in St. Louis for the year 789, of which 508 in June and July.

1854.—Cholera as virulent in St. Louis as it was in 1849. Total deaths 1,534, mainly in May, June, July and August.

1855.—Disappeared from the United States.

1853, 1854.—Prevailed in Great Britain,

1855, 1856.—The allied armies in the Crimea suffered intensely.

1865-1874.—Cholera persisted in Europe about ten years.

1865.—In the beginning of May it broke out with terrible fury among the pilgrims at Mecca. On the 10th or 11th of May the first death occurred at Alexandria. In June it had reached Cairo. On the 3d of July at Constantinople, where it produced a terrible panic. From Alexandria a steamer conveyed it to Marseilles. From thence travelers carried it to Paris.

1865, September.—Several cases at Southampton, England. Did not spread.

1865, November 3.—Steamship Atalanta came into the lower bay of New York with 400 German immigrants, and cholera. Precautions taken; no spread.

1866, July 7.—At Ancona in Italy, from Alexandria.

1865.—Great epidemic at Valencia, in Spain. Thirty-one out of forty-nine provinces in Spain were ravaged from July till the close of the year. It extended also into Portugal.

1866.—Cholera was early reproduced in almost all the localities it had visited in 1865. It extended northward as far as St. Petersburgh. It appeared in several localities in Bavaria, Saxony and Prussia, also in Belgium and Holland. It still existed in Paris and extended to the northwest of France.

1866.—An epidemic in Liverpool from July 22, to the end of November carried off 1 792 victims. In London for the four weeks ending August the 4th, the deaths were 63,481, 1,097, 1,178. More or less diffused over England during the summer.

1866.—It broke out in New York about the beginning of May, and gradually spread over the country, following the lines of travel. Prevailed extensively in the United States army, causing over 1,200 deaths among officers and men. During summer and fall prevailed extensively at New Orleans. Prevailed at St. Louis also.

1867.—A general abatement in Europe. Prevalent in South America. Buenos Ayres suffered greatly.

1867.—At New Orleans, reappeared in June; 571 deaths the following six months. Again at St. Louis during summer and fall.

1868.—Completely died out in Europe.

1869.—By its old route it reached Nijni Novgorod, and broke out in September.

1870.—A vast outburst of cholera. In Russia, 9,386 deaths.

1871.—In Russia, 124,834 deaths.

1872.—In Russia, 113,196 deaths.

1873.—In Russia, 4,395 deaths.

1872.—Very widely diffused over Europe. Imported into England on several occasions. Its spread stopped by the local sanitary authorities.

1873.—Began to subside in Europe.

1872, December, and 1873, January.—There arrived at New Orleans a total of nearly two thousand immigrants from cholera infected districts of Europe.

1873, February 9.—First death at New Orleans. Two hundred and fifty-nine fatal cases occurred during the epidemic.

1873, April 8.—First case, fatal, at Vicksburg.

1873, June 30.—First case, fatal, at Little Rock. Four importations; no spread owing to the energy and efficiency of the medical men in whose care the initial cases occurred.

1873, April 15.—First case, fatal, at Memphis.

1873, May 24.—First case, fatal, at Chicago. Total number of deaths from cholera and cholera morbus, May and September, one hundred and sixteen. Many towns and villages suffered greatly.

1873.—First case at St. Louis, died 11th of May. A mild epidemic followed. Other localities visited.

1873.—First case at Paducah, died May 21. Very widely diffused throughout Kentucky.

1863, June 15.—First death reported at Cincinnati. Two hundred and seven deaths during the summer. Other cities and towns in Ohio visited.

1873.—June 6.—First death at Evansville. Other localities in Indiana visited.

1873.—During June and July sixty-two deaths at Huntsville, Ala., Birmingham, with about three thousand inhabitants, was terribly scourged during June and July.

1873, June 15.—First case, fatal, at Wheeling.

1873.—But two authenticated cases of cholera occurred in the State of Georgia. Both were residents of and refugees from Chattanooga. One died at Atlanta, population 22,000, on July 2. The other, at Dalton, population, 5,000, on July 3. Both instances terminated fatally in communities in which the auxiliaries to the rapid development of a cholera epidemic were present, the specific causes once having been imported; yet in both instances, by the prompt and energetic action of the medical men having the case in charge, the power of the disease was confined to the infected individual, and the health of the residents of the respective houses and of each community were efficiently guarded.

1873.—During this year some two hundred cities and towns in the Mississippi valley were more or less afflicted. See *Public Health*, Vol. I, pp. 224-252.

1882.—Made its appearance in Egypt, where in three or four months it occasioned a mortality of 30,000 to 50,000 of the inhabitants.

1884.—On June 13 or 14, it invaded the French military post, Toulon. Then the cities of Toulon and Marseilles, and spread through the south and southeast of France, and partly in central and western France.

1885.—At Marseilles and in Bretagne.

1884.—About August, in Spain.

1885.—Invaded almost the whole of Spain.

1884.—Brought into Italy.

1885.—Great ravages at Palermo, Sicily.

1885-6.—At Venice.

1886.—From April during the rest of the year it ravaged the peninsula of Italy.

1886.—At Trieste, and also the Austro-Hungarian shores of the Adriatic.

1887.—Again in Sicily and in Italy.

1884-1887.—The epidemic of cholera in Europe cost France 15,000 inhabitants in 1884, 1885 and 1886; Spain, 180,000 inhabitants in 1884 and 1885; Austro-Hungary, 4,000 inhabitants in 1886; Italy, about 50,000 inhabitants in 1884, 1885, 1886 and 1887; Malta, 500 inhabitants in 1887; a sum approximately of 250,000 inhabitants of Europe. In other words, the epidemic has removed from France about one inhabitant for every 3,000, from Italy one inhabitant for 550 or 600, from Spain one inhabitant for every 100, from Austro-Hungary one inhabitant for every 9,000. An approximate calculation of these losses, estimated from the purely material point of view, shows a sum total of about $80,000,000 of value destroyed. A still greater loss resulting from the damages caused by the disease through idleness, interference with commerce and navigation, interruption of business, etc., would increase the sum total of the losses occasioned by the cholera to about $200,000,000 in three or four years. See report of E. O. Shakespeare, M.D., U. S. Commissioner.

1886.—Cholera introduced into Buenos Ayres, Argentine Republic, in November, by the ship Perseo, plying between that city and Genoa. A conspicuous instance of official pride and stupidity. An extensive epidemic developed, and the disease spread through the inland provinces. The city was cut out entirely from the commercial world; Uruguay, Brazil, Paraguay, and most of the European ports quarantined against it.

1887, January 19.—Cholera officially declared at Montevideo, Argentine Republic, after many denials of its existence.

1887, January 2.—Cholera at San Felipe, a town situated near the base of the Andes, 40 miles north of Santiago. The latter city severely scourged. Commerce of Chili interrupted, with heavy losses.

1887, September 23.—The steamship Alesia arrived at New York from Marseilles with cholera on board. At Naples some 600 immigrants, from the cholera districts of Italy and Sicily were taken aboard. Proper precautions used by the quarantine officials and the disease not allowed to spread. Much credit claimed, and justly, considering their limited means.

However, the case of the Italian steamer Independente, which arrived in New York in October with a large number of immigrants, and not showing cholera on board, was allowed to discharge her passengers, after a few hours of detention, necessary for a thorough inspection, shows the insufficiency of this New York safeguard. The next day numerous squads of these immigrants, with their baggage, departed for at least twelve great cities, in widely distant parts of the country.

CHOLERA IN EUROPE 1892.

1892, June 27.—At Baku, the Russian port on the Caspian, 48 new cases and 38 deaths. The town in a deplorably filthy condition, and without the least pretense of sanitary arrangement.

June 30.—Rome—Five cases have occurred in Italy.

July 1.—The administration of the towns in the Asiatic provinces of Russia taking energetic measures to prevent its spread.

July 1.—Many cases reported in the outskirts of Paris.

July 6.—Saratoff on the Volga scourged.

July 8.—Panic in Astrakhan.

July 11.—In Paris 14 deaths.

July 14.—Terrible in Astrakhan.

July 17-21.—Russian official returns announce 4,839 cases and 2,590 deaths for this period.

July 23.—Advance toward the Russian frontier. Absorbs public attention in Berlin.

July 23.—At Nijni Novgorod and Moscow. Expected at St. Petersburg.

August 5, 6.—Cholera returns for all Russia these two days show a total of 6,741 new cases and 3,496 deaths. Prior to August 1, total deaths, official, 23,919.

August 1-12.—In St. Petersburg 154 cases and 31 deaths between these dates officially admitted.

August 11.—In Northern and Central Russia increasing. In Moscow many factories closed.

August 13.—Returns for Russia this day show a large increase in new cases and mortality.

August 15.—Total number of new cases reported in Russia, 7,600; total deaths, 3,900. Two-thirds of the towns attacked can make no reports for lack of telegraphic connections.

BOOK REVIEWS.

TREATISE ON THE DISEASES OF WOMEN. FOR THE USE OF STUDENTS AND PRACTITIONERS, by ALEXANDER J. C. SKEENE, M. D. Second edition, revised, enlarged and finely illustrated. New York: D. Appleton & Co., 1892.

The first edition of this valuable work at once received from all students of gynecology the stamp of commendation, as it was a most excellent exponent of the most advanced professional knowledge of diseases of women. Its immediate adoption as a standard text book in the colleges, indicates its appreciation by both teachers and students.

That the work may be continued in this high position, its author has thoroughly revised the book and added new chapters on ectopic gestation, diseases and injuries of the ureter, vesical hernia and its surgical treatment. While his latest views, particularly find expression in the chapters on laparotomy, ovaritis and injuries of the cervix uteri and pelvic floor. Typographically, the book is a work of art.

HUMAN MONSTROSITIES, by PROF. BARTON COOKE HIRST, M.D., and PROF. GEORGE A. PIERSAL. Part iii, with nine photographic reproductions and thirty-four wood cuts. Philadelphia: Lea Brothers & Co.

This, the third volume of this highly artistic and scientific work, has many features of attractiveness. The plates comprise beautiful illustrations, from photographs, of typical specimens of rhinocephalus, cyclocephalus, acephalus and diprosopus. The plates represent the various monstrosities in several positions, thus giving a most accurate demonstration of the peculiarities of each, and enabling the seeker after information, to classify any particular specimen quite readily.

SEVENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF KANSAS. For the year 1891. E. H Snow, State Printer, Topeka. 1892.

This is the first report issued under the direction of the new secretary, Dr. M. O'Brien, of Topeka. We seem to miss the practiced hand of Dr. J. W. Redden, whose reputation as a sanitarian is as wide as the country. His resignation took effect in July, 1891, and it can hardly be expected that we will see his signature again in an official capacity. We trust that the Commonwealth he well served has not been ungrateful towards him.

This volume presents more popular reading than is commonly found, and we judge that its contents are aimed to do missionary labor in political fields that are disinclined to perform their full sanitary duty. The following epistle appears in the Report to show the opposition met by the State Board in their efforts to establish local boards of health.

"*two the board of helth offiscer of the Stait of Kan.*

"threw request of docter ——— of ———, I wish to write and Stait that the board of county cometioners have concluded mot to hier a county helth oficer as it Seems to bee the publick centiment of the peopel of this county that it is a waist of public funds to pay a pyhfesetion to look of the helth of this county and it seems to bee an imposibilety to get the docters of this county to make a report of the berth and dethe of the county and aS an impartiel report is aquivelent to now report a tall the county cometioners have decided to retain the services of docter ——— as a Kind of a figuer head in case of an epodemic to act as help oficer and mke Such reports as seems best and the board a Grees to pay him according to his work.

respectively yours

———, *Chairman of the board of County cometioners.*"

The writer of the report adds:

"This communication is not introduced to illustate the humor of the situation, although the situation does, at long intervals, take on a humorous aspect; nor is it introduced primarily to disclose the insufficiencies of the "Chairman of the board of County cometioners." To write and read come by nature, and have been called a vanity. We desire only to call attention to the degree of obliquity against which Health Boards must make head, even in enlightened Kansas."

But the County Commissioners are not the only dealers in phonetic discourse. In another part of the report is printed the letter of a practitioner of Greencastle, Missouri, who, being "too grossly ignorant and illiterate to be permitted to engage in practice elsewhere, find ready asylum here,"—in Kansas, sent an inquiry to the Board. It is with reluctance that the Secretary confesses that the writer of the following could settle in Kansas any day or hour he may elect:

> "Dear Sir i Would like to know What the laws is in regarde to the practice of medicin in the state of Kansas is a man aloud to practice their With out a certificat from a medical School i have ben tolde that the board of health gave permishon in that State if so when does board meet and if i can get the endorsement of three practicing physicians Would that do or Would i half to come before the board."

The old plea of "fair play" is worn threadbare in the cases of such pretenders as these, and yet this plea speciously and persistently presented has thus far defeated every effort toward the passage of proper restrictive legislation. On pages 70, 104 and 224 are given some very sharp home-thrusts against the different charlatans who thrive on the sufferings of Kansas citizens. The long-haired itinerant with his band-wagon and female accompaniments, whose pranks and antics serve to beguile a tedious day appears as an especial pest. Having quoted so much from this Report we purpose to take one more selection, giving a sweeter, nobler picture —and one which we are thankful to say finds frequent mention in the literature of the present time—an able man's reminiscences of his family doctor. The writer of the following sketch from life is Chief Justice Horton of the Supreme Court of Kansas.

> "I recall with affectionate remembrance our family physician, upon whom from my earliest childhood I looked with youthful reverence and unquestioning faith. Before me, to-day, I see his kindly face and listen to his pleasant voice. He was a very hero, in my eyes; of commanding figure and magnificent physique. There could be no finer, braver, better man. He was the wise counselor, the skilled restorer, the sympathetic friend. The silver had crept into his hair, and careful thought and much exposure had lined his brow, but there was ever about him a brightness and cheeriness which seemed a part of his presence, only that it lingered after he had gone. I recollect that one of our neighbors went raving crazy, and with a gleaming razor menaced a crowd which gathered around him. But the doctor, alone, rushed dauntlessly forward, overpowered and unhanded him, exhibiting a physical courage and prowess sufficient to win the heart of any boy. Yet it was not this instance of fearlessness in time of danger which in my maturer judgment went furthest to prove his resolution and heroism. It was the tried and constant disregard of self, through the long years of a varied practice. No call was disregarded; no contagion appalled, no storm or tempest ever dismayed him. The humble and poor received his attentions in equal measure with the wealthy and influential. All of his life he went about doing good, ministering to the afflicted. His heart was in his work. His zeal, energy, patience, skill and industry combined in modeling the man fit for the highest ideal of life.
>
> 'A combination and a form indeed,
> Where every god did seem to set his seal
> To give the world assurance of a man.'"

Judge Horton's entire address is an argument to show why legislation is proper that will make men like the foregoing a staple product of the State, and make the long-haired ignoramus a contraband and fugitive. Judge Horton would seem to be a "tower of strength" to legitimate medicine in his State.

MISCELLANY.

Unfit for Colonization.—An agent of Baron Hirsch reported that the Jewish peasants in the Odessa district are so degraded that the Argentine Republic would not allow them to be sent to the Jewish colony there, and that it is therefore expected that they will be sent to the United States.

The death of Dr. Thos. F. Wood, the well-known editor of the *North Carolina Medical Journal*, is briefly announced in that publication.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending August 27, 1892.

P. A. Surgeon C. W. Rush, from special duty in connection with the International Railway Commission, and to the Navy Yard, New York.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Three Months Ending August 20, 1892.

Surgeon P. H. Bailhache, granted leave of absence for fourteen days. May 25, 1992.

Surgeon George Purviance, granted leave of absence for seven days. August 9, 1892.

Surgeon John Vansant, granted leave of absence for thirty days. August 13, 1892.

Surgeon H. W. Austin, granted leave of absence for thirty days. June 21, 1892.

Surgeon G. W. Stoner, to proceed to Port Huron, Sault. Ste. Marie, Saginaw, Marquette, Mich., Duluth, Minn., and Superior, Wis., as inspector. July 11, 1892.

Surgeon F. W. Mead, granted leave of absence for thirty days. August 3, 1892.

Surgeon H. R. Carter, to proceed to Chicago, Ill., as inspector of unserviceable property. August 16, 1892.

P. A. Surgeon Eugene Wasdin, granted leave of absence for twenty-eight days. July 21, 1892.

P. A. Surgeon J. H. White, granted leave of absence for thirty days. August 13, 1892.

P. A. Surgeon P. M. Carrington, granted leave of absence for twenty-seven days. August 13, 1892.

P. A. Surgeon W. B. McIntosh, granted leave of absence for thirty days. July 8, 1892.

P. A. Surgeon G. M. Magruder, granted leave of absence for seven days. August 18, 1892.

P. A. Surgeon R. M. Woodward, granted leave of absence for twenty-five days. August 1, 1892.

P. A. Surgeon J. B. Stoner, granted leave of absence for twenty-six days. August 13, 1892.

Asst. Surgeon A. W. Condict, granted leave of absence for twenty-six days. July 21, 1892.

Asst. Surgeon S. H. Hussey, to proceed to Galveston, Texas, for temporary duty. August 11, 1892.

Asst. Surgeon C. P. Wertenbaker, to proceed to Pittsburgh, Pa., for temporary duty. August 9, 1892.

Asst. Surgeon J. C. Perry, to proceed to Charleston, S. C., for temporary duty. July 19, 1892.

Asst. Surgeon A. C. Smith, granted leave of absence for twenty-eight days. August 13, 1892.

Asst. Surgeon M. J. Rosenau, to proceed to Cairo, Ill., for temporary duty. July 27, 1892.

Asst. Surgeon L. E. Cofer, to proceed to Norfolk, Va., for temporary duty. June 10, 1892. Granted leave of absence for twenty-three days. August 6, 1892.

Asst. Surgeon J. M. Eager, to proceed to Evansville, Ind., for temporary duty. August 11, 1892.

Asst. Surgeon J. A. Nydegger, assigned to temporary duty at Baltimore, Md. July 6, 1892.

Asst. Surgeon W. J. S. Stewart, to proceed to New York, N. Y., for temporary duty. July 6, 1892. To proceed to Wilmington, N, C., for temporary duty. July 19, 1892. To proceed to Savannah, Ga., for temporary duty. August 9, 1892.

PROMOTIONS.

Stoner, J. B., commissioned as P. A. Surgeon. June 30, 1892.

Guiteras, G. M., commissioned as P. A. Surgeon. July 27, 1892.

APPOINTMENTS.

Nydegger, James A., M.D., of Maryland, commissioned as Asst. Surgeon. July 1, 1892.

Stewart, William J. S., M.D., of Pennsylvania, commissioned as Asst. Surgeon. June 30, 1892.

The Journal of the American Medical Association

Vol. XIX. CHICAGO, SEPTEMBER 10, 1892. No. 11.

ORIGINAL ARTICLES.

A FEW EXPERIMENTS WITH THIERSCH'S GRAFTS IN THE OPERATION FOR PTERYGIUM.

Read in the Section of Surgery and Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June 8, 1892.

BY F. C. HOTZ, M.D.,
PROF. OF OPHTHALMOLOGY IN CHICAGO POLICLINIC, CHICAGO.

A pterygium is nothing but a fold of ocular conjunctiva drawn over and fastened to the cornea, and to make our operation for pterygium a permanent success, we must after releasing the conjunctival fold from the cornea, arrange matters so that the conjunctiva cannot be drawn back over the cornea again. In a pterygium of moderate size this aim is usually attained by a very simple operation. The conjunctival fold is carefully dissected from the cornea, and allowed to retract as far as it will. from the corneal margin. This leaves between the retracted conjunctiva and the cornea, a small wound area to close which we draw the conjunctiva from above and below together, and unite the edges by two sutures. If this wound heals by first intention, there is no danger of a recurrence of the pterygium.

But in a number of cases the pterygium is so large, and the gap in the ocular conjunctiva after its dissection and retraction is so wide that it is very difficult, sometimes almost impossible, to close it with conjunctival sutures. At all events, the strain upon these sutures is so great that often they cut through in the first twenty-four hours and allow the wound edges to separate. The resulting gap is then gradually closed by granulation tissue, which is also filling the corneal area from which the pterygium has been removed. And when this new tissue begins to consolidate into a cicatrix, its shrinkage will gradually pull with an irresistible force the ocular conjunctiva over the cornea again. The pterygium has returned; our operation is a failure.

These failures make everyone wish for an operative procedure which promises better results. When, therefore, last year in August, I had occasion again to operate on a pterygium of this unpromising kind, I decided upon trying a new plan. I had by this time convinced myself in a number of cases of symblepharon that the thin skin shavings obtained by Thiersch's method are an excellent material for patching up defects in the conjunctiva. I give them decidedly the preference to graftings of mucous membrane; for the Thiersch grafts are much easier to handle and to fit; they need no sutures; they grow better and shrink much less. And as to appearance, they are as smooth as the surrounding conjunctiva, but look paler, more whitish.

Now it seemed to me worth the trial to fill the gap in the ocular conjunctiva caused by the dissection of a broad pterygium, with one of these Thiersch skin grafts; for if it adhered it would most assuredly keep the conjunctiva away from the cornea, and as it probably would look whitish, its color would blend well with the white of the eyeball.

These considerations induced me to try the skin grafting in the pterygium case last August. The pterygium reached to the center of the cornea, and the sides diverged from the apex backwards so rapidly, that when they crossed the corneal border they included about one-fourth of the corneal circumference. This pterygium was dissected off from the cornea,and the subconjunctival fibres which bind the pterygium to the sclera and cause the foldings of the conjunctiva,were carefully and thoroughly divided all the way back to the caruncle so that the conjunctiva could retract and unfold itself. The retraction left a large area of the sclera (10 mm. wide and 12 mm. high) denuded of conjunctiva. To fill this defect I shaved a Thiersch graft from the inside of the patient's forearm, transported it from the razor directly to the denuded sclera and spread it out smoothly over the entire wound. I had cut the graft a little larger than the wound so that when the graft was smoothened out over the sclera, the edges of the conjunctiva were overlapping the graft. My idea in tucking the edges of the graft under the conjunctiva was that the overlapping conjunctiva would assist in keeping the graft in place, and protect its edges against being rolled up or wrinkled by the frictions of the eyelids on the eyeball during the latter's rotations. But this part of the plan did not work well; for on the next day I found the edges of the graft were not under but even with the conjunctiva, and the graft reached about 2 mm. over the cornea. It had evidently been pushed toward the cornea just so much as it had been tucked under the conjunctiva. On the third day when I was satisfied the graft was firmly attached to the sclera, I lifted the edge which overlapped the cornea and trimmed it back even with the margin of the cornea. At first the graft had a pink color; but after the second week it was white, being covered with epidermoidal cells which could easily be scraped off. Later on the layer of epidermoidal cells become thinner but firmer, and now (I saw the patient on April 23 the last time) the surface of the graft is smooth and shining, and only a very little higher than the ocular conjunctiva. It has shrunken a little, more in the horizontal than in the vertical diameter; but it holds its place well, and forms a firm immovable bar which makes it absolutely impossible that the conjunctiva should ever again be drawn into the cornea.

In February I applied the same plan to two other cases of pterygium; but profiting by the experience of my first trial I cut the grafts smaller than the defects they were to patch up. In the second case the defect measured 12 by 10 mm. and in the third eye 6 by 10 mm.; the skin grafts were cut 10 by 8, and 5 by 8 mm., respectively. Both took well and though after two months their horizontal diameter was reduced from 10 to 6 in the one and from 5 to 3 in the other eye, they still serve the purpose well of holding the conjunctiva back from the cornea.

I do not wish to draw any positive conclusions from these few experiments; but it seems to me they show that Thiersch's skin grafts readily adhere to wounds on the eyeball; that they may be utilized in patching up defects in the ocular conjunctiva; and that the insertion of a Thiersch graft may prove a valuable means to make the operation for pterygium a permanent success, even in the worst kind of cases.

Discussion.

Dr. A. E. Prince, Springfield, Ill.:—The valuable paper of Dr. Hotz commands recognition. I think the work an excellent one. I have had two cases in which there has been a similar experience and the results have been so satisfactory as to lead me to be very much encouraged. In one of the cases the conjunctival complication was a symblepharon. I transplanted a considerable portion of conjunctiva from a white rabbit's eye and greatly ameliorated the condition. In the second case the transplantation was taken from the inner surface of the lip and the purpose was to overcome a blepharophimosis. I took out a rhomboid section of mucous membrane of the lip and transplanted it. The result was very good in the relief of the symptoms.

Dr. G. C. Savage, Nashville, Tenn.:—I am inclined to the opinion that the reason for some of the returns of pterygium is to be found in the condition of the cornea left after removal. I do not think that it is proper to attempt to dissect off by instruments the corneal attachment of a pterygium. In that way we leave an unfavorable condition for the development of epithelium so as to rapidly cover in the denuded surface of the cornea. We leave some of the growth when we attempt to remove it by scissors or knife. I have never operated after the method of Dr. Prince in peeling off the corneal attachment with a strabismus hook, although I think that it would be better than the use of the knife or scissors. My plan is to make a puncture above and below the growth at the corneal margin through which I pass one blade of the scissors and make a V shaped incision with the opening toward the cornea. Then dissecting up carefully to the cornea I seize the loosened growth with fixation forceps, instruct the patient to look towards the nose while I pull in the opposite direction when every vestige of the growth is removed. Of course if there is much of the sclera exposed because of the broad base of the pterygium, then I conceive that the operation of Dr. Hotz is a good one, and I shall make use of it. If the open space is not so great, the edges of the conjunctiva can be brought together by sutures; and, before cicatricial tissue has formed, the corneal abrasion has been covered by epithelium. My experience is that the pterygium is not likely to recur after this method of operating. This operation is not new to me. I got the idea from some one, but I can not now say where.

Dr. H. M. Starkey, Chicago.—I should like to make a suggestion in regard to a method of treatment of pterygium which I have employed with highly satisfactory results in a few cases, not a sufficient number to make a report upon, but simply to suggest that others may try it. It is particularly adapted to those cases where there is a minimum amount of fibrous tissue and a large amount of vascular tissue. The method is that of electrolysis. We know how quickly a mild current of electricity will shrivel up blood vessels. In a case of pterygium which seemed to be composed almost entirely of blood vessels, it occurred to me that electricity would be of service. I therefore employed the negative current in a strength of one or two milliampères with a platinum needle pressed under the growth and in two sittings the blood vessels were obliterated and the condition has not recurred. This is a painless operation under cocaine, is followed by little reaction and no mutilation. I have used it in half a dozen cases and have been well pleased with it.

Dr. A. R. Baker, Cleveland, O.:—It seems to me that the suggestion of Dr. Hotz is of immense value in symblepharon in which there is excessive loss of conjunctival tissue, but I think that it can not take the place of the old operation of transplantation of the pterygium below the cornea. You simply transplant the healthy conjunctiva to the place occupied by the pterygium. I have done this operation a number of times and have never felt the need for any other. Where the pterygium is very broad split it and put one part above and the other below the cornea. In this way we can manage any pterygium no matter how large.

Dr. J. E. Minney:—I use Prince's method in the main and find it very good. If I find that a portion of the pterygium remains I take a knife and scrape it off aiming to get it entirely smooth. I find that if I destroy the blood supply at the margin of the cornea, there is less liability to a return. The method which Dr. Hotz suggests is one that I shall give a trial. I have had cases in which I needed just such a method.

Dr. Henry D. Noyes, New York:—I had not the pleasure of hearing the paper of Dr. Hotz, but I should like to make a statement in regard to pterygium. In former times I regarded incipient pterygium as of no importance and thought it not necessary to interfere, but I have changed my views and in the last five years, experience has shown me that it is important to deal with pterygium even at an early period before it has advanced toward the middle of the cornea as it interferes with the curvature of the cornea. I have found by examination with the ophthalmometer the cornea rendered astigmatic by the pressure of a pterygium and that its removal has altered its curve. For this reason I have made up my mind that it is desirable to operate for pterygium at a period when it does not mechanically cause any interference with sight.

Dr. F. C. Hotz, Chicago:—As to the method of removing the corneal part of the pterygium, I cannot see why the removal should be less complete if we carefully dissect the conjunctival part from the cornea with a scalpel than if we remove it by the brute force of pulling. I am always opposed to any brutal manipulation about the eye and this pulling out of a pterygium looks to me like one of these manipulations. I think that I can more accurately gauge my interference with the tissues with the knife because I can control the effect of my cutting absolutely, but if I tear I cannot control that any more than when I tear a piece of cloth. But whether you remove it by traction or by the knife, there is a denuded surface of the cornea which must heal. If superficial, it may heal over at once with epithelium. In an old pterygium where the superficial layers of the cornea have been involved, it fills up with granulation tissue and forms a scar; and as this scar extends from the cornea back over the sclera, it draws upon the ocular conjunctiva and pulls it towards the cornea again.

The philosophy of transplanting the pterygium I could never understand except on the ground that the pterygium is a foreign growth, and from the remarks of Dr. Baker, I am inclined to think that he takes that view. But a pterygium is no new growth, but the conjunctiva which has become changed by chronic inflammation and drawn into the cornea. Fuchs has recently published a paper in which he says in regard to the histology of pterygium that it is a conjunctival fold in which there has been chronic inflammation with subsequent changes in the connective tissue, one of the characteristic features of which is a predominance of elastic fibres. Whenever you lift up a pterygium, you can see that it is connected loosely with the sclera, except along a transverse line following the extension of the horizontal meridian of the cornea toward the caruncle. Along this line, the conjunctiva is bound to the sclera by firm bands like cicatricial tissue and when these are cut you will see that the conjunctival folds spread out smoothly.

This goes to prove that the peculiar foldings of the conjunctiva in the pterygium are produced by the contraction of the subconjunctival connective tissue.

THE CARTWRIGHT PRIZE FOR 1893.—The usual award of this prize, valued at five hundred dollars, will be made in June, 1893. The alumni of the Medical Department of the New York College of Physicians and Surgeons are the sponsors for this valuable premium for original medical investigation. Any person may compete, and he may write upon any subject connected with the science of medicine. About the only restrictions are the provisos that the prize may not be given to two or more persons working jointly, or to a competitor who has sent his essay elsewhere to compete for another prize. The personality of the author should be, as is the usual rule, concealed, and the papers must be sent to the secretary of the alumni on or before April 1, 1893.

OSTEOMA OF THE ORBIT, REMOVAL WITH PRESERVATION OF VISION.

Read before the Section of Ophthalmology, at the Forty third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY EDWARD JACKSON, M.D.,
PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC, SURGEON TO THE WILLS EYE HOSPITAL.

The following case seems to me to be of sufficient importance to place upon record:

Miss M., æt. 18, had noticed two years before, a swelling of the left upper lid, pretty uniform and unaccompanied by pain or soreness. This swelling has since then increased gradually until the present time. For the last few months, there has been some pain over the upper inner angle of the left orbit.

About one year ago she noticed that the vision in the left eye was not so good as in the right, but the eyes had not previously been separately tested, and there has been no deterioration of vision since. In the right eye the vision is as good as it has ever been. In the right eye the media are clear; there is hyperopic astigmatism; the disk is oval clear, of good color; fundus dark, normal. Left eye, media clear; higher hyperopic astigmatism; disk oval, clear, of good color; arteries bear due proportion to veins in size. Muscle tests, show right hyperphoria of from 0 to 1 centrad; laterally there is muscular balance, power of abduction 5 centrads; adduction 10 to 12 centrads; sursumduction, right or left, 1 centrad. A hard tumor is felt below the upper margin of the left orbit from which it is separated by a distinct though narrow sulcus. It extends from the inner third to the outer angle of the orbit, and about one centimetre in the vertical direction. The left eye is displaced downward one centimetre and forward eight millimetres. No lateral displacement can be recognized.

1891, October 9, I removed the tumor. A free incision was made through the upper lid just below and parallel to the upper margin of the orbit, and the growth freely exposed by the retraction of all the soft parts; it proved to be entirely hard and connected with the roof of the orbit by an apparently broad base and to extend more than half way back to the apex of the orbit. The exposed surface was bitten away with rongeur forceps. But it was soon evident that these would remove but a small part of the growth. The saw was tried but could not be used to advantage. The chisel gave no result, because I feared to apply sufficient force, not knowing at what point it might cause fracture. With a hand drill however, three holes were made in different directions, and the intervening bone split with the chisel, separating the growth from its attachments, and dividing it in two principal fragments which were then extracted. During this process, there being a tendency to extrusion of the globe between the lids, at the suggestion of Dr. Risley, these were stitched together and the stitch removed at the completion of the operation. The attachment to the walls of the orbit proved to be upward and inward three-fourths of an inch back from the orbital margin, and the removal of the tumor opened the ethmoidal sinuses so that blood escaped through the nose. The tumor weighed about 13 grams. The wound was washed out with bichloride solution, a catgut drain brought out at the outer angle, and the wound closed with seven sutures; a gauze dressing was applied with a bandage, so as to make firm pressure on the lower lid. The operation was done under ether and lasted one hour and three quarters.

The temperature did not rise above the normal, the wound closed by first intention. Drainage and sutures were removed on the seventh day. At the first dressing, next morning, there was found considerable swelling, especially of the conjunctiva which protruded between the lids, and could not be entirely returned. Next day, the protruding portion was snipped off, after which the swelling and hyperæmia rapidly diminished. At the end of two weeks the swelling was greatly reduced and the globe had almost, but not entirely returned to its normal position. There was, however, very little power of moving the eyeball, and diplopia was experienced in all parts of the visual field except the centre. There was complete ptosis.

From this time there was rapid improvement in the motility of the globe, and at the end of four weeks she experienced diplopia only in the extreme periphery of the field of binocular vision. The ptosis had decidedly lessened. One month later, her recovery was complete except a moderate ptosis. Her condition continued the same up to the time she was last heard from. With Right + 0.25 sph. ⊃ + 2. cyl. ax. 110°, V.= 4-4 mostly. Left + 0.25 sph. ⊃ + 3. cyl. ax. 65°, = 4-15, about the same as before the operation.

It is interesting to note in this case that although the tumor appeared in the outer two-thirds of the orbit, its origin was from the upper inner angle about three-fourths of an inch back from the orbital margin, and the displacement was directly forward and downward.

Although the eye-ball had been carried forward to the extent of almost a centimetre and the insertions of the muscles to that extent removed, there had been no squint or diplopia, there was very little heterophoria, and no marked weakness of the ocular movements.

All the movements of the eyes except the elevation of the upper lid were completely restored within a few weeks.

In the removal of the exostosis which was throughout almost its whole extent, of ivory like hardness, the common bone drill worked simply by hand, penetrated rather rapidly and proved by far the most efficient as well as the safest means of attack.

A CASE OF RARE FORM OF ORBITAL TUMOR..

Read in the Section of Ophthalmology at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY G. E. FROTHINGHAM, M.D.,.
OF DETROIT, MICH.

Cases in which tumors are developed in both orbits are extremely rare. That the tumors should occupy exactly the same position in each orbit, and correspond in form and size, and develop at nearly the same time, is still more remarkable. For these reasons, as well as some other unusual characters, I have thought the following case worthy to be put on record.

Miss E. D., age sixteen, of Canton, Michigan, consulted me January 11, 1892.

The father gave the following history: In May, 1890, she noticed a tumor of the left orbit. There was no pain in the tumor or protrusion of the eyeball, but the tumor projected somewhat, and was situated above the eye, extending from the inner extremity of the superciliary ridge to the outer canthus, and causing a prominence parallel with, and just below this bony arch. The tumor felt hard and was slightly movable on firm pressure. She visited the clinic at Ann Arbor, and had an operation for its removal, in December of the same year. A large firm tumor was removed. The eyeball protruded after the operation, presenting the appearance shown in the photograph here presented which was taken on the 10th of May last. The recovery from the operation was rapid, the patient leaving the hospital in about a week after it was performed. While recovering from the effect of the operation, she was feeling about her right eye, and noticed a tumor over it in the same position as the one which had been removed from the left orbit. It had also the same feeling and was slightly movable; she also noticed before she left the hospital that there was a small tumor at the outer portion of the left orbit and also one near the center of the lower portion below the eyeball.

At the time I examined her, there was a large tumor of the right orbit, causing a prominence projecting to about the same level with the bony margin, and about an inch and a half in length on its anterior border. It was situated above the levator palpebrarum and close to the orbital plate of the frontal bone. The eyeball was displaced downward and there was double vision, except when looking sharply downward, the image of the right eye being above that of the left. There was a tumor at the outer margin of left orbit, slightly movable and apparently extending deeply inward. There was also a small, very movable tumor below the left eye, which still remains. On the 14th of January, assisted by my son, Dr. G. E. Frothingham, Jr., and by Dr. L. Connor, I operated for the removal of the tumor of the right orbit.

An incision was made along its anterior border down to the tumor, which was carefully dissected from the surrounding tissues, by means of the handle of the scalpel and probe pointed scissors. When this had been done, the tumor was carefully dragged from its bed, bringing with it the firmest strands of connective tissue, which extended inward from its deep border at the bottom of the orbital cavity. The supra-orbital nerve was so intimately blended with the tumor, that it had to be sacrificed. After the hæmorrhage had ceased, a small drainage tube was inserted sufficiently deep to allow escape of any blood that might accumulate from subsequent oozing, and the edges of the cut then brought together by suture, and the wound dressed with cotton saturated in solution of bichloride of mercury, 1-2000. There was but little reaction, and the patient left the hospital in one week from the operation, with the wound healed and the parts almost entirely free from swelling. The double-vision was completely relieved by the removal of the tumor. The tumor measured a little more than an inch and a half along its anterior border, and about the same along its posterior border. It extended also a little more than an inch and a half into the orbit. It was wedge-shaped, the base forming the anterior portion of the tumor. The thickness of the firm portion was, at the base, a little more than three-eighths of an inch at the inner extremity, and slightly over one-fourth of an inch at the outer extremity. It grows gradually thinner, as it approaches the edge. It is very firm to the feeling like fibro-cartilage, and resembles on section the appearance of dense, white fibrous tissue, or condensed connective tissue.

There was some degree of ptosis of the lid, after the operation, but that was soon recovered from. There has been no sign of recurrence of the tumor of the right eye up to the present time. There is no resulting exophthalmus, and vision is unimpaired. The patient being anxious to be relieved from the proptosis of left eye, I operated upon it on the 10th of May, last Making an incision, extending the outer canthus, and then dividing the palpebral ligaments of both lids to a sufficient extent. I thus made an opening sufficiently large, without endangering the nerve supply of the orbicularis. Through this opening I removed a tumor about three-fourths of an inch long, half an inch wide, and one-eighth of an inch thick, extending into the orbit behind the globe. The periosteum seemed thickened at the bottom of the orbit, but no distinct tumor could be felt. The tumor below the eye could not be removed through this opening, and I thought it more judicious to leave it for a subsequent operation, than to make so extensive dissections at one time. The wound was treated as in the operation upon the right eye. The inflammatory reaction was, however, much greater, and seemed quite threatening during the first thirty-six hours. It then began to subside. The conjunction was much swollen, however, and it was two weeks before it could be fully replaced under the lower lid. The vision is unimpaired and the proptosis seems less though not greatly diminished by the operation.

An examination made by Dr. George Duffield, shows the tumor to be a fibro-sarcoma, with the fibrous element very largely predominating—a tumor that is sometimes called a fibroma. It seems to develop from connective tissue, and is not a frequent form of sarcomatous tumors. It is said that a preponderance of cellular elements is the peculiar feature of all sarcomata. At any rate, those I have found, either within the eye or the orbit, were rich in cells and quite friable, instead of being firm and tough like the one here presented. I believe such tumors nearly always become very rich in cells, and have blood-vessels within them before they have grown to the size this one had reached.

The tumor removed from the left orbit by Prof. Carrow, Dec. 4, 1890, was reported by the pathologist as a sarcoma, but the variety was not given.

Discussion.

Dr. H. Knapp, New York:—I beg to make some remarks especially with reference to the paper of Dr. Frothingham. I wish to point out the difficulty in diagnosis in some of these cases, as on three occasions I have fallen into a great mistake. Some of these tumors are benign although they present the features of malignancy. I remember three cases of this kind. The *first*, was an individual, about 20 years of age, with a tumor situated deeply in the orbit producing exophthalmus. It was supposed to be a sarcoma and yet it completely disappeared.

In the *second* case, there was considerable exophthalmus from large growths in different parts of the orbit. The eye was taken out by one of the surgeons of the Manhattan Eye and Ear Hospital and the tumor cleanly removed. On microscopic examination, it was pronounced to be a small-celled sarcoma. The patient came to me two years later with the same condition in the other eye. There was great protrusion of the eye and solid masses were distinctly felt in the orbit. I could not advise the woman to have that eye removed and I was not sure that otherwise the radical removal of these tumors could be accomplished. She was under general treatment and three or four months afterward I heard that she was better and that the tumors gradually diminished in size. After about 15 months she again came to me and was perfectly cured. The growths and the exophthalmus had disappeared without leaving a trace and without any injury to the functions of the eye.

Another case was sent to me last year, by Dr. Morgan, of Springfield, Massachusetts. The tumor had sprung from the inner side of the orbit and seemed to be connected with the periosteum. It looked like a periosteal sarcoma. Dr. Morgan removed the growth and the microscope showed that it was sarcoma. That patient had similar growths in the nasal passage of the same side. It seemed to be a case of sarcomatous growths of the nasal passages protruding into the orbital cavity. After the removal by Dr. Morgan, there was a rapid relapse. In several months the growth was as large as before. The tumor seemed to go into the wall of the orbit so deeply that I did not think any operation could be done with benefit. The orbital small celled sarcomata are as malignant as any tumors can be. This patient after leaving me went to an electrician and also took some indifferent remedies. She perfectly recovered. She said that the improvement began after being under the electric treatment for four or six weeks and had steadily continued. Not long ago she presented herself to me and there was no trace of the trouble left. The orbit was normal and the nasal passages were free. She came to express her gratitude that I had advised her not to be operated upon.

What are these growths that come under the mask of sarcoma and evidently are not malignant? They are not fibromata for they do not disappear. The only thing that I can imagine is that they are lymphomata. In the first case the diagnosis of lymphoma was not so difficult because there were swellings in other parts. It was a symptom of Hodgkin's disease. In the other two cases, there was nothing to lead me to such a diagnosis. The disease was purely local. The histology of the tumor was in all the same, a small celled tumor with more or less fibrous tissue. When

I see such a tumor, if I am sure that it is not in connection with the orbital walls, I hesitate to advise its immediate removal. If it progresses there is nothing else to be done. If the tumors are multiple and malignant, we cannot do any good. If there is such doubt and I think the doubt cannot be entirely excluded, I would rather wait before committing myself to the removal of the eye or tumor.

The different elements which constitute these tumors may perhaps lead to the diagnosis of lymphoma. We must also bear in mind the possibility of diffuse or disseminate sarcoma which is the worst kind of all. We think to have removed them cleanly and it is not two months before you see tumors in the neighborhood. Some of these cases have been sent to me for operation after some of the tumors have been removed. I have removed the orbit's contents cleanly to the periosteum and on examining them I have found all through the orbital tissue, patches and nodules of sarcomatous tissue. In one case the diffuse sarcoma was melanotic and had invaded the optic nerve. These points are to be taken into consideration in the diagnosis of these tumors of which some are certainly benign.

Dr. Reeves, Toronto:—Seventeen years ago I enucleated an eye for sarcoma in which there was found a melanotic tumor. The tumor was not examined microscopically. It was a firm tumor occupying a large portion of the vitreous chamber. About sixteen years later, two years ago, the patient again presented himself. For fifteen years there had been no sign of disease of the orbit. On examination I found indications of sarcoma of the orbit and two years ago last October, I operated. The patient had marked cephalalgia. I cleaned out the orbit completely and applied chloride of zinc. Microscopical examination showed the tumor to be a melanotic sarcoma of the optic nerve. The patient is in good health with no sign of return of the growth. The cephalalgia disappeared in a few weeks after operation.

I do not consider this a case of true recurrence of sarcoma, I do not believe that sarcoma can remain latent for fifteen years. It is a case rather that may be explained on the principles of the abnormal development of embryonic tissue which existed there from the beginning.

Dr. Julian J. Chisolm, Baltimore:—About a month ago, I had occasion to take out an eye in a case that presented the question, at what period during the existence of an intra-ocular tumor is systemic infection established? The patient had bad detachment of the retina with absolute loss of vision, for one year but unaccompanied by pain. A week before I saw him the first pain was experienced. The eye was much injected, there was the usual tension, and the pupil was slightly dilated. These were all evidences of an intra-ocular growth and a correct diagnosis was made although the detachment of the retina excluded the use of the ophthalmoscope. When the eye was removed and opened, I found a growth not larger than a pea which proved itself a melanotic sarcoma. It had infiltrated the sclerotic although the inflammatory symptoms with tension had existed only one week and the tumor did not occupy one-sixth of the vitreous space.

Dr. S. C. Ayers, Cincinnati:—I have recently had a case of tumor of the orbit, which was to me, one of extreme interest. I first saw the patient a year ago last March. There was a little exophthalmos and vision was considerably reduced. There was infiltration of the optic nerve and under the lower lid one could feel a suspicion of a growth. I again saw the patient a week or ten days later. Vision had fallen to one-half and I thought that I could feel that the tumor had developed in these few days. I gave my opinion that it was a sarcoma originating in the apex and pressing forward rapidly and that vision would be more and more reduced and advised removal of the tumor and removal of the globe if necessary. I thought that it was not possible to save the globe. I saw the patient no more until fall. He went elsewhere and an attempt was made to remove the tumor and save the globe, but the attempt was not successful in either direction. Panophthalmitis followed the operation and the man suffered intensely for a long time and the tumor again began to grow. When I saw him in the fall, there were four or five large firm nodules around the rim of the orbit. I said then that it was useless to do anything. I saw the patient from time to time, but the tumor was evidently not growing forward, but was clearly advancing toward the brain. He was soon bed fast and his nutrition seriously impaired. He lost flesh and in February had paralysis of the right arm. The tumor involved the right eye. He died about six weeks ago. During the latter part of his illness there was observed a ridge or elevation in the periosteum extending upwards and following the suture of the parietal bone. The bone was tender. He also complained a good deal of pain in the region of the cerebellum.

When the post-mortem was made we found that the parietal bone and the upper portion of the frontal and of the occipital bones were softened. The parietal was so softened that it could almost be penetrated with a knife. The internal surface of the parietal was covered with a growth looking like granulations. The internal and external surface of the dura was covered with a similar deposit. The granulations on the internal surface were larger and more exuberant than those in other places. The sphenoid bone could be cut with a knife. The tumor had not involved the brain, but had simply grown over the anterior surface and pressed it down. The operation originally would have had no more influence than to prolong life for a little while. The extension of the growth backwards and the involvement of the bone and dura mater was something new in my experience.

Dr. Johnson, Paterson, N. J.:—I agree with Dr. Knapp as to the necessity of considering carefully the desirability of making these operations, on account of the possibility that the tumors may be benign in their nature. At the same time I had occasion to see a month or two ago a case in which, after operation was advised, delay had been made as a result of the desire of the patient's family. When the tumor became sufficiently increased in size to alarm them, they permitted operation, which was followed in a short time by rapid recurrence of the tumor and death of the patient. I think that it is desirable, if operations on orbital tumors are to be made, that they should be made early. I have operated on a number of orbital tumors, some of which were sarcomatous in their nature; one in particular, on which I operated eight or nine years ago, was reported in the *Archives of Ophthalmology.* The growth was examined microscopically by Dr. Prudden, and pronounced to be a myxosarcoma of the optic nerve. Up to this time there has been no recurrence. Whether or not this was one of those tumors with a malignant appearance and a benign effect, I cannot say. In these tumors presenting a malignant appearance it is desirable that they should be removed as soon as we can make up our minds whether they are malignant or benign while it is still possible to remove the entire growth.

Dr. J. A. White, Richmond, Va.:—I have seen cases of sarcoma which did not recur. Fibroma is not in its nature malignant, but I consider it more malignant than ordinary sarcomatous growths, because it almost invariably recurs. I have seen only three cases of fibroma of the orbit, and in every case there was recurrence. I think that it is difficult to state how much the fibrous change has taken place in certain tissues, because of the little difference microscopically from the normal appearance.

In regard to whether or not the last growth will recur, I do not know, because I have never seen a case of miliary tuberculosis of the orbit before.

Dr. George E. Frothingham, Detroit:—I should like to add one word in connection with these tumors. It has been questioned here whether a melanotic sarcoma can remain stationary as long as fifteen years. I remember a case where a melanotic sarcoma of the choroid had ruptured through the external tunics. It was thoroughly removed, but after six or eight years, it recurred. All the contents of the orbit were then removed, and after four or five years, it again returned.

As to the question of the malignancy of these growths, I think that we have very imperfect knowledge. One fact has been well established, that is that some of these cases will never recur, while in others operation seems to stimulate their growth. In 1876, I had a peculiar case which bears upon this matter. A patient came with a painful, blind eye, the lens opaque and the iris attached to the lens, and the tension increased. He had such severe pain that enucleation was decided upon. Fearing malignancy, the nerve was cut as far back as possible. After removing the tumor, I examined the eye, and found about the optic nerve some connective tissue which felt a little harder than normal. Internal examination showed no tumor within the eye. It was simply a case of chronic inflammatory disease. A few months afterward the patient came with a large mass protruding from the orbit. I think that within five months after the eye had been removed, that immense mass developed. It was so evidently malignant that I at once decided to operate. The whole contents of the orbit were removed. The growth was so closely connected with the bony wall of the orbit that I decided to apply chloride of zinc paste. This produced necrosis of the bony wall, so that the brain protruded into the orbit, and then the wound granulated.

His physician reported a few months later that he had died with all the evidences of malignant disease of the kidney. Examination showed the growth to be a giant-celled, rapidly growing sarcoma.

Another case occurred in a child 2 years of age. A firm tumor was found at the outer part of the orbit. It had the feel of a sarcoma, and connective tissue was found extending into the bone. It was cut loose, but rapidly recurred, and the child died.

THE ETIOLOGICAL RELATION OF NASAL DISEASES TO AFFECTIONS OF THE EYES.

Read in the Section of Ophthalmology at the Forty third Annual Meeting of the American Medical Association, held at Detroit. Mich., June 1892.

BY DR. H. GRADLE,
CHICAGO.

Within the past eight years various publications have appeared intended to show a connection between certain ocular and nasal disturbances.

The proof that lesions of the orbit, eye and its appendages or symptoms referable to these parts are induced by preëxisting nasal diseases, can be furnished in various ways, viz.:

1. We may trace anatomically the extension of disease of the nasal cavity into the orbit or into the appendages of the eye.

2. We may observe clinically the involvement of these parts or of the eye itself in disease consecutive to and in direct connection with nasal disease.

3. We may influence in a characteristic manner by means of nasal treatment eye effections the prognosis of which is definitely known.

4. More decisive than these methods is the experimental production of eye lesions in animals in consequence of nasal disturbances. As yet, nothing has been done in this line. But practically equivalent to experiments on animals are various observations of disturbances in the eyes or lids following experimental irritation or irritant treatment of the nose in patients.

Of these different modes of proving the connection between ocular and nasal diseases the first method is the most definite one, no matter whether we trace the extension of the disease during life or at an autopsy. The second way, the clinical observation of the evolution of the ocular disorder demands reliance upon the patient's statements, since the physician can but rarely see such cases at their incipiency. The sequence of the two disorders is after all only suggestive of the dependence of one upon the other; it is not an absolute proof. It is only the repeated observation of cases with similar histories in this respect that can establish the etiological relationship with some certainty. But it must not be demanded that because a certain eye disease is of nasal origin in some instances it should always depend upon the same etiological conditions.

Most of the writers on this subject have employed the third mode of reasoning—that is to say, the therapeutic test.

When they observed an improvement in certain eye symptoms after nasal treatment they reasoned that the nasal condition has been the cause producing them.

This mode of reasoning however, is beset with errors, against which we must guard ourselves. The prognosis is not always so certain in the class of diseases principally referred to, especially asthenopic complaints, so that an improvement following any given treatment can be attributed to that treatment only if it sets in very promptly. We must be sure that neither other measures employed, nor the mere lapse of time are responsible for the patient's improvement.

Moreover, in estimating the beneficial results of any new treatment, particularly of a surgical character, upon nervous symptoms we must not ignore the possibility of mental suggestion. For these reasons as well as on account of the short period of their observation some of the cases and conclusions recorded in literature are not as convincing of the relation of the nose to the eye, as their authors claim.

When the question arises whether actual ocular lesions and not mere functional derangements are to be considered as secondary results of nasal disease the therapeutic test cannot be regarded as an absolute criterion. For lesions once started do not necessarily cease on removal of the conditions that induced them. In such instances the etiology can only be established on the basis of careful histories.

American authors have mostly dealt with functional derangements only, but cases published by Gordon, de Schweinitz and various European observers, as well as my personal experience, point out that also different lesions of the eye and its appendages may be of nasal origin.

On the basis of personal experience, and aided by the published observations of others, I shall attempt to classify the various ocular derangements dependent upon nasal disturbances, and will aim to distinguish critically between actual proof of such connection and mere probability of nasal origin.

I. In diseases of the *lachrymal passages* nasal affections are found present in the majority of instances [20 22 40 and personal experience] †. In speaking of nasal diseases or anomalies, I refer to demonstrable lesions or marked deviations from the normal shape, no matter whether they give the patient annoyance or not. If we were to diagnosticate nasal disorders only on the strength of the patient's statement as to the discomfort in the nose, we we would overlook many instances of chronic disorders in the less observing class of people. On the other hand, whenever I speak of acute nasal catarrh, I do not rely on the patient's reference to a "cold," but demand a definite history of the symptoms of coryza.

The mere coincidence of nasal disorders, so common in our climate, with lachrymal disease, is far from being a proof of their correlation. Stronger, however, is the evidence that in one-sided lachrymal disease the affected passage corresponds almost invariably to the more abnormal side of the nose. A direct proof that the nose is the starting point of the disease of the tear-canal can only be obtained when an intelligent patient observes the insufficiency of the tear duct or the inflammation of the sac beginning during an acute attack of nasal disease. Of such instances I have a number in my records. I do not wish to overlook, however, that occasionally lachrymal disease, especially narrowing of the canaliculi, is the result of conjunctival disease.

The therapeutic test is not decisive in lachrymal affections. Neither in stricture of the duct nor in suppuration of the sac, can removal of the nasal lesions restore the integrity of the lachrymal passage without surgical treatment of the diseased part. But that nasal treatment can aid the local procedures in maintaining the patency of the lachrymal passage is proven by the cases published by de Schweinitz,[40] as well as by some similar observations of mine.

---

† The figures in brackets refer to the authors quoted at the end.

It may be in place to point out a source of error in estimating the influence of nasal treatment upon diseases of the tear-passages. *Lachrymation* is not necessarily indicative of obstruction of the tear canal. An abnormal flow of tears may result from disease of the conjunctiva or eye as well as—in many persons at least—from nasal irritation, even when the tear canal is normal. On the other hand, an obstructed duct leads to an overflow of tears only when they are secreted in excess. Some patients with stricture, or even after obliteration of the sac, have epiphora only when the eye is irritated by wind. Nearly all authors who have written on the relation of the nose to the eye speak of lachrymation as a symptom produced by nasal irritation and cured by nasal treatment. The beneficial influence of nasal treatment, when undertaken in connection with local measures directed against the disease of the lachrymal passage, is therefore not a definite proof that the lesion in the duct or sac was cured thereby. It signifies only that the excessive reflex secretion of tears has been stopped.

II. The *eyelids* are the seat of occasional vascular disturbances in persons with irritative forms of nasal disease. The attacks may amount to a transient *circumscribed œdema*, perhaps analogous to urticaria, or may resemble *erythema*, or even a *pseudo-erysipelatous* condition. The attack may be one-sided or bilateral. Hack[1] claims to have proven their nasal origin by several observations in which they followed the use of the galvano-cautery in the nose, while in some other instances their habitual recurrence ceased after nasal treatment. I[15] have seen about half a dozen of such attacks, but have never had the opportunity to follow the results of nasal treatment for a sufficient length of time to prove the nasal origin by the therapeutic test. In every instance, however, there was the history of habitual nasal irritation with an acute exacerbation preceding the skin trouble.

Blepharitis has seemed to me to be dependent in some instances upon nasal disturbances. I have repeatedly observed the squamous form of this disease relapse during treatment when the patient got a fresh coryza. A few times, I have seen the inflammation of the lids cease spontaneously, after a cure of the coexisting nasal condition, for which the patient had applied to me. On the other hand, I have three times seen an ulcerative blepharitis, in which I could easily stop the ulceration by local measures, but could not remove the parenchymatous inflammation of the edge of the lid until I began to treat an atrophic rhinitis evidently maintaining the blepharitis. In these instances the condition of the lid improved in proportion to the amelioration of the nasal process.

III. Of diseases of the *conjunctiva*, I have seen not very rarely a *subacute conjunctivitis* occurring during the course of a fresh coryza. Its dependence on the nasal trouble seemed probable, because its course ran parallel to that of the coryza. While its intensity could be reduced by use of nitrate of silver or sulphate of zinc, it could not be checked with the same promptness as ordinary conjunctival catarrh. A similar conjunctivitis likewise rebellious to all treatment, is often seen in hay fever. I have formerly described a form of periodic hypertrophic conjunctivitis allied to hay fever (*American Journal of the Medical Sciences*, April, 1886), but cannot say whether this condition depends on nasal trouble

Chronic *congestion* of the conjunctiva is often observed in connection with chronic nasal irritation or stenosis, and will not be found to yield to any treatment except removal of the nasal anomaly. The congestion is not necessarily limited to the lining of the lids. Indeed, the history that an eye without active inflammation, is at times bloodshot, I have found to be quite characteristic of irritation of nasal origin. Such eyes are apt to be irritable. I have seen several cases of injection of the conjunctival and scleral vessels with considerable smarting or burning of the eyes maintained by protracted follicular inflammation of the pharyngeal tonsil, sometimes without marked discomfort in the throat. The dependence of the eye disturbance upon the pharyngeal infection, was shown by the prompt influence of applications of nitrate of silver to the inflamed adenoid tissue.

The conjunctival congestion may pass into *catarrhal* inflammation. I take this to be a secondary infection, because it is easily arrested by conjunctival treatment, but is apt to relapse unless the underlying nasal disorder is removed. But cases have also been reported, first by Gordon, and since by other American authors in which a severe chronic conjunctivitis with thickening of the mucous membrane did not yield to any local measures, but were promptly cured by the cure of a rhinitis.

Attention has been called by Ziem and by Despagnet[32] to the frequent coexistence of trachoma and nasal catarrh. There is no proof, however, that they are related to each other, although some observations like those of Taylor[26] make it not improbable that nasal trouble can account for the obstinacy of some cases of trachoma.

IV. A dependence of some *corneal* diseases upon nasal disorders is probable, but not yet definitely established. Trousseau[23] speaks of 11 instances of corneal ulcers which did not heal promptly until an ozœna present was treated. Yet the case given in illustration is by no means conclusive of any connection.

Phlyctenular keratitis and the *punctiform corneal infiltrations* of scrofulous children, are as a rule accompanied by a sero-purulent rhinitis.[33] In some instances, I have seen every relapse of this form of corneal disease preceded by nasal obstruction and discharge. Nasal disease does not, however, exist in all cases. The therapeutic test is rarely conclusive, though often suggestive of a nasal factor in the causation of phlyctenular keratitis. As a rule, the corneal trouble yields readily to local treatment. Still I have seen a fair number of children in which the corneal disease lingered while the nasal condition had received no attention, either on the part of other competent oculists or a few times in my own practice. In some of these instances the treatment of the rhinitis was followed by prompt improvement of the corneal lesion, in others, however, not.

Three times I have seen a very characteristic type of corneal disease in the form of flat papules on the limbus and pinhead-sized specks of infiltration in the cornea supplied with bundles of blood vessels comparable to the so-called fascicular keratitis. The individual lesions were of long duration, and left cloudy spots on the cornea, while relapses protracted the course for months. In every instance there was a marked diffuse hypertrophy of the nasal mucous membrane (not merely of the cavernous tissue) and with it thickening of the external nose. The pharyngeal tonsil was moderately enlarged in two of the cases. The disease was not influenced by any treatment. But the negative result does not exclude a nasal origin, for while the surgical treatment improved the patency of the nose it did not lead to full integrity of the nasal lining during the time of observation. Two of the cases got well spontaneously; the other one was lost sight of. (See also Ziem [8].)

V. *Iritis* occurs occasionally though not frequently during an acute coryza. The possible connection between the two affections is emphasized by the statement of some intelligent patients with relapses of iritis, that every attack was preceded by acute nasal inflammation. Ziem [17] has also noticed the occurrence of iritis in connection with suppuration of the nose and accessory cavities and thinks that nasal treatment exerted a distinct influence in one instance.

VI. *A not well defined intraocular affection suggestive of chronic glaucoma* has been observed—once by Berger [13] following a galvano-caustic operation in the nose which resulted in necrosis of the nasal wall—while Ziem [14] has reported three such instances caused by intra-nasal cauterization. The eye involved corresponded to the injured side of the nose. The patients had either slightly reduced central vision or what was more characteristic with it a restricted field of vision and diminished accommodation.

In Ziem's cases there was venous congestion and pulsation of the papilla. The sight improved spontaneously, but the histories do not proceed until complete recovery. Ziem [23 24 27 29] subsequently reported several more observations in which similar symptoms, notably the restricted field of vision, occurred in patients with empyema of the maxillary sinus, but ceased after cure of the suppuration. Several times there was suspicious hardness of the eyeball. In two of the patients with disease of the antrum on both sides the sight of one eye had previously been destroyed by some intraocular process, apparently cyclitis. Lennox Browne [16] also refers to a case of chronic glaucoma not benefited by iridectomy, but apparently arrested and the sight improved by the removal of nasal polypi.

Ziem attributes these attacks of reduction of sight, field and accommodation to intraocular congestion especially of the ciliary body. There is, however, no proof of their glaucomatous nature; they do not even correspond to the prodromal stage and excavation of the papilla was never present. The case mentioned by Browne is not described sufficiently to be intelligently criticized. I could find no other observation of this kind on record and have never seen the condition in any of my patients with empyema of the antrum.

VII. The *optic nerves* are separated from the cavity of the sphenoid sinus by a bony wall, frequently quite fragile and not rarely imperfect. Disease of the sphenoid sinus, suppuration, caries or tumors may hence lead to compression and neuritis of the chiasm and intracranial portion of the optic nerves. Berger and Tyrman [10] collected 23 cases of this nature from the literature up to 1880, and in his latest monograph Berger [43] refers to 5 additional instances. Some of them, however, were due to growths of the sphenoid bone, and hence cannot range amongst eye affections of nasal origin. Various authors seek the cause of retrobulbar neuritis in infection through the sphenoid sinus. However plausible this view may be, it is in no way proven, and the cases quoted by Berger [43] p. 37, are not convincing of such an origin.

VIII. *Neuritis* of the *nerves supplying* the *muscles* of the eye seems to depend occasionally upon nasal inflammation according to my own observations. During the past 18 months I have seen but three instances of paralysis of ocular muscles, the course of which characterized them as of peripheral, not syphilitic origin. In all these cases the paralysis was preceded by a severe nasal catarrh in the course of which persistent headache set in, which was then followed by the sudden paresis. Twice the nerve involved was the abducens, once the extraocular fibres of the third nerve. All three ended in recovery. The inference that the neuritis resulted from extension of the nasal infection was strengthened in one case by the existence of a polypus high up on the same side of the nose.

IX. *Orbital disease* may be simulated by morbid processes in either the frontal or the ethmoid sinus. As the consideration of such instances is almost foreign to our subject, I will refer simply to the reviews by Berger and Tyrman [10] and by C. Stedman Bull.[39] But suppurative inflammation of these cavities may indeed penetrate into the orbit, leading to circumscribed *orbital abscess* as in the cases recorded by Peltesohn.[19] To what extent the numerous instances of orbital phlegmon and of tenonitis observed after influenza, resulted from the extension of inflammation in the nasal and accessory cavities is a subject worthy of further study. Various instances of *orbital tumors* also took their origin from the ethmoid and frontal sinuses.[10-43]

In rare instances, neoplasms of the nasal cavity may also invade the orbit. Nieden [9] reports two cases of malignant growth in the nose entering the orbit, one directly by perforation, the other by way of the cranial cavity. Personally, I have seen a cavernous growth of the nasal cavity extend into the orbit. The vascular tumor originating in the nose and filling one side of it completely, was radically removed by the use of the galvano-cautery in the course of some ten weeks. During the course of treatment, the orbit became invaded by a vascular new-formation, presumably of the same nature as the nasal tumor. This however, receded again spontaneously, and after the lapse of some three months, there remained no evidence of any orbital tumefaction.

The orbital congestion and tumefaction, together with the other disturbances which constitute *exophthalmic goitre* have in a few rare instances been entirely removed by the treatment of intra-nasal anomalies. The fact that there are but seven observations of this kind on record, shows that a nasal origin of this disease is a very rare occurrence. But the prompt disappearance of the symptoms—usually so persistent—of Basedow's diseases after nasal treatment in six [6] of the instances, is as decisive a proof of their dependence upon the nasal anomaly as any therapeutic test can furnish.[1]*

---

*Hopman, Deutscher Natuaforscher Congress 1885, reprinted in Berliner klinische Wochenschrift 1888, No. 42. Hack, Deutsche med, In another striking case reported by Semon (*Internat. Centralblatt f. Laryngologie*, VI, p. 238) one-sided exophthalmus and palpitation of the heart were provoked by a galvano-caustic operation in the nose, but subsided after the lapse of a few days.

X. The most common ocular affections of nasal origin are the *sensory* and *functional derangements.* In my experience, I find that in every 100 patients applying on account of refractive anomalies or asthenopic complaints, there are about two to three instances with subjective symptoms curable by nasal treatment. The nasal origin of these symptoms can be proven only by the therapeutic test, for which there is a proper field whenever no cause for the complaints can be found in the eyes or their muscles. There is nothing characteristic in the history of these cases. The annoyance from the nasal trouble may or may not be slight. The development of the eye symptoms is generally gradual, but sometimes they occur in a more acute form during the acute aggravation of a preëxisting nasal disease. The anomaly causing them is most commonly some obstructive lesion in the nose often, though not invariably, associated with nasal irritability. A few times I have also seen marked ocular discomfort produced by subacute follicular inflammation in the tonsils or at the vault of the pharynx.

a. The eye symptoms described by authors [5 6 7 11 12 15 18 21 25 26 30 31 33 36 41] as of nasal origin, are itching, burning and smarting of the lids, shooting pains through the eyes, sometimes a heavy, full feeling, but not often an actual ache. Characteristic of the nasal origin is their presence immediately on awaking. Usually there are remissions in the severity of the annoyance during the day. Sometimes there is associated with this discomfort, more or less injection of the conjunctiva, even of the eyeball and lachrymation. The sensitiveness to light may be exaggerated to an extent causing tonic blepharospasm, but often, too, there is no photophobia or irritability.

The eye-discomfort due to nasal disease is in some persons not increased by use of the eyes. In others, however, all eye work intensifies the symptoms so as to render steady use of the eyes impossible. I have formerly[15] come to the conclusion that this asthenopia is of mixed origin. Most of the sufferers of this type show on examination some refractive or muscular anomaly. If this is corrected they can use their eyes with greater ease, but yet are not free from discomfort. If on the other hand, the nasal condition can be cured the patients enjoy comfort while they rest their eyes, but require their glasses for work. The cases published by De Schweinitz[41] seem to conform to this view. I do not think, however, that this combination of refractive (or muscular) asthenopia with nasal influence is accidental. It has seemed to me that the nasal influence renders the nervous system sensitive to a degree of eye strain, which normal persons with the same optic conditions can usually bear without discomfort. Some of my patients have indeed been able to drop their glasses without suffering some time after the cure of the nasal disorder.

There are, besides, other instances in which nasal lesions alone, cause typical asthenopia for work even in emmetropic persons. In my experience this type has not been common. A striking case has been reported by Kibbe.[42]

Hoffman[4] has called attention to asthenopia due to failure of the accommodation in persons with cheesy accumulations in the tonsils, and claims to have cured such patients by treatment of the tonsils. I have likewise been able to benefit a number of young persons by excision of the tonsils or destruction of the distended crypts. In my cases, however, I could not demonstrate an absolute diminution of accommodative power, as measured by the distance of the near point, but the strain or blurring on use of the eyes seemed to depend on an inability to maintain continuously the required accommodative effort.

b. Another functional trouble which in some instances seems of nasal origin is fugitive scotoma or blind headache. Hack[1] p. 36, describes two instances of this kind in which the spells of migraine with scotoma scintillans ceased after galvano-caustic destruction of excessive cavernous tissue in the nose. I have seen a number of instances in which a connection between such attacks, and the nasal condition was suggested by correspondingly one-sided obstructive lesions with irritative symptoms during the attack. But I have only had opportunity twice to satisfy myself of the persistent cessation of the blind spells after successful nasal treatment.

c. Blepharospasm can sometimes be traced to nasal influence. Persistent closure of the lids may result from the photophobia engendered by nasal disease, as reported in an extreme instance by Bettman,[12] or by suppuration of the maxillary sinus as seen by Nieden.[9] But cases also occur in which clonic spasms of the lids, or even chorea of the orbicularis and facial muscles, are stopped by the removal of nasal anomalies. Ziem[8] has seen such cases subsequent to the removal of enlarged pharyngeal or faucial tonsils. Jacobi (*N. Y. Med. Record*, January 30, 1886) has also called attention to the influence of naso-pharyngeal disease in the production of facial chorea. Personally I have seen not very rarely chorea of the lids and of the face in children suffering from subacute rhinitis, in whom the gradual cessation of the muscular twitching in proportion as the nasal disease was improved can be considered positive evidence of the nasal influence. In some instances I have been able to demonstrate the nasal origin by means of the calming effect of a cocaine spray. In others, however, the experiment with cocaine, as well as the result of treatment, have led me to attribute the chorea to irritation proceeding conjointly from both morbid nasal and diseased conjunctival surfaces.

Two observations reported, the one by B. Fraenkel (*Berliner Klin. Wochenschrift*, No. 22, 1884), the other by Peltesohn (*Berl. Klin. Wochenschrift*, No. 32, 1891), show that even typical one-sided tic spasmodic, involving the orbicularis as well as the other facial muscles, may be a reflex of nasal origin.

d. The possibility of reflex contractures of ocular muscles in consequence of nasal lesions is illustrated by a singular observation published by Quinlan,[37] in which convergent squint occurred after a fracture of the nasal septum, lasted ten years, and disappeared spontaneously after operative correction of the deflected bone.

Wochenschrift 1888 No. 25. Fraenkel, B., Berliner klin. Wochenschrift 1888, No. 6. (Goitre and cardiac symptoms without exophthalmus.) Stoker, Internat. Centralblatt f. Laryngologie, V, p. 579. (Two cases.) Musehold. Deutsche med. Wochenschrift, 1892, No. 5. (Goitre and cardiac symptoms, no exophthalmus, but one-sided ocular pain, cured by removal of a small hypertrophy from the rear end of the inferior turbinated body.)

In trying to answer the question how nasal disorders can lead to these eye symptoms and lesions, we must take into account four possible modes of causation:

1. Processes of growth cause the extension of tumors through the sinuses into the orbit or into the cranial cavity. Hypertrophies also may involve mechanically the nasal end of the nasal duct.

2. By extension of infection through lymph vessels, through foramina or deficiencies in the bony walls, or along continuity of surface, inflammatory processes may pass from the nose into the orbit, may reach the intracranial portion of the optic nerve, or may creep into the lachrymal sac. Clinical observation shows that this spread of infection is favored by narrowness of the nasal passage, or by obstructions interfering with the drainage of pus.

3. Circulatory disturbances may occur in the form of venous congestion whenever mechanical conditions exist in the nose which impede the circulation. This is particularly the case in nasal obstructive lesions. We can often see the resulting stasis in the form of dark venous rings around the lids, and in the congestion of the edges of the lids. The anatomical conditions which determine the involvement of the orbital and palpebral veins in nasal disturbances are the anastomoses between these vessels and the veins of the nose, which connections vary in different subjects. Besides the passive venous engorgement, there may occur active congestion of the conjunctival, and perhaps also of the intraocular vessels, in connection with acute or irritating nasal inflammations, comparable to the congested zone surrounding any inflammatory focus. Both the active and the passive vascular disturbances are probably accompanied by interference with the lymphatic circulation. That this disturbance of nutrition should reduce the resisting power of the ocular tissues to accidentally present germs, is a presumption supported by many pathological observations.

4. Lastly, the nasal influence may consist in nervous disturbances—the so-called reflexes. This is evidently the mode of production in blepharospasm of nasal origin, and in abnormal lachrymation. Vascular disturbances may also be of reflex origin, as can be demonstrated by irritating the nasal mucous membrane in sensitive persons, or by extracting a hair at the entrance of the nose. Some of the sensory derangements of the eye are likewise due to the irritation of the sensory nerve of the nose, a proof of which can sometimes be given by the calming effect of nasal spray of cocaine. To call them reflexes, however, is a misuse of a physiological term. A better name would be sensory neuroses of peripheral (*i. e.*, nasal) origin.

HETEROPHORIA AS A CAUSE OF ACUTE RHINITIS, LOSS OF SMELL AND TINNITUS AURIUM.

Read in the Section of Ophthalmology at the Forty-third annual meeting of the American Medical Association, held in Detroit, Mich., June. 1892.

BY LEARTUS CONNOR, M.D.,
OF DETROIT, MICH.

That diseases of the nares affect the functions of the eyes unfavorably in many directions, is a well accepted fact the confirmations of which are numerous and constantly increasing. In some ways it has been recognized that disorders of the eyes disturb the functions of the nares. Thus all those eye diseases that increase or diminish or render ichorus the secretion of the conjunctiva and lachrymal glands, definitely modify unfavorably the functions of the nares, often exciting severe inflammations which can only be relieved by the abatement of the disordered secretion, or the rendering of it normal in quantity and quality. Farther, it is a matter of record that defects of refraction by inducing disorders of the conjunctival secretions modify the functions of the nares in many important particulars.

Thus a disorder of the eyes may originate in a disorder of the nares, and a disorder of the nares may originate in a disorder of the eyes. My purpose is not a discussion of these intercurrent relationships in general, but to present a single observation upon a single point among these relationships. By this I hope to show that in one instance a condition of exophoria uncomplicated with any other discernable abnormality did induce an acute rhinitis, a loss of the sense of smell, a tinnitus aurium, and a general nervous prostration. The instance I give briefly.

On July 24, 1891, Miss G. H. applied to me for relief from severe and frequent attacks of acute rhinitis, tinnitus aurium and loss of smell. She was a strong healthy appearing woman, single, a type writer by occupation, and twenty-eight years old. She said that aside from these troubles she had never been sick, and had been able to follow her calling during the past twelve years without scarcely a vacation. Her troubles began very gradually, but she was able to show that they had existed for at least a year and a half previous to July 24, 1891. First she suffered only from the attacks of rhinitis. After about six months she noticed a loss of sense of smell, and about seven months later the tinnitus aurium. The constitutional disturbance attending the attacks was slight at first, but had gradually increased in intensity until it had become so severe as to almost incapacitate her for work. The attacks of rhinitis occurred at somewhat irregular intervals, averaging about one a week and lasting from two to four days. During the attacks there was a constant flow of watery fluid from the nose, compelling her to keep a handkerchief to her nose nearly all the time, and thus seriously interfering with her work. To provide a receptacle for this fluid from half a dozen to a dozen handkerchiefs were needed daily. With the fluid was more or less mucous and some little pus. The character of the fluid or the mechanical results from wiping the nose produced a great amount of excoriation about the vestibule of the nose. During these attacks the mucous membrane of the nose became red, rough, sensitive and the turbinated bodies so swollen as to quite occlude the nasal passages on one or both sides. Sometimes one nostril would be most affected, and sometimes the other, and again both.

Accompanying these attacks was great and indescribable general distress which continued for a time after the attacks disappeared. No external condition seemed to have any effect upon this onset or departure. They were as frequent during fall and winter as during spring and summer. Foul air, dust, emanations from flowers or vegetable matter did not seem to interfere with them in any particular.

They were, however, increased in frequency and force by over work and over heating.

An examination at first visit showed a condition of the nares identical with that already described. The sense of smell was entirely absent. The hearing for R. E. was $\frac{17}{48}$, for L. E. was $\frac{6}{48}$ as tested by watch. The tuning fork and Politzer's acumeter gave similar results. The membrana tympani of either side exhibited the characteristic appearances of chronic non-suppurative otitis media plus an acute attack of inflammation of the middle ears, as shown by a red line along the handle of the malleus, lack of lustre, and diminished mobility. Her eyes were not examined, for the reason that she gave no symptoms referable thereto. She had for a year and a half previous to my seeing her, been under the care of an expert in diseases of the nose and throat, but without appreciable relief, in fact she had steadily grown worse in all respects.

Regarding the case as one of recurring attacks of acute rhinitis extending to the mucous membrane of the upper pharynx, Eustachian tubes and middle ears, I managed it accordingly. The greatest relief was obtained by the application to the engorged mucous membrane of trichloro-acetic acid. This clearly shortened the attacks and lessened their severity, but they still recurred, and the attending disability of hearing, loss of smell, and tinnitus remained. No modification of her time or place of work, or other changes in her mode of life suggested by the circumstances produced any marked improvement.

Finally it occurred to me that in spite of the fact that she did not complain of her eyes or head, and did her work with ease when not suffering from the attacks of rhinitis, that a waste of nerve energy would be prevented by the correction of her exophoria. She would not consent to an operation upon the stronger tendons, so that recourse was had to prisms. On Feb. 12, 1892, I gave her to wear before each eye, a prism of three degrees. This was but a partial correction of her exophoria, but it added to her comfort so markedly, that in a few days they were increased to four degrees, and a few days later to six degrees. This corrected her exophoria to within a half a degree. There was no hyperphoria, nor any defect of refraction, her vision being normal in all respects.

The effects of wearing these prisms may be briefly stated. Without any local treatment of her nose she had no return of her trouble for a couple of weeks. This was so peculiar that she was requested to lay aside the prisms. The result was a prompt attack of rhinitis of the old type. She was then permitted to resume the wearing of the prisms, and will not part with them because convinced of the relief they afford her. To date of writing, some three months, she has been entirely free from these attacks. Gradually the tinnitus diminished, until for the past two months she does not recognize it. Even attacks of ordinary cold do not affect her differently from other persons. Her hearing has increased in her R. E. to $\frac{18}{48}$, and in her L. E. to $\frac{10}{48}$. The membranes of the ears have assumed a more healthful appearance. Her sense of smell returns more slowly, but it is surely increasing. Her habits and mode of life have remained as they were during the local treatment to the nares and ears. The most careful scrutiny of this case fails to reveal any other cause for the attacks described, than the exophoria.

In conclusion it is to be noted:

1. An exophoria of twelve degrees uncomplicated with any other deformity or disability of the eyes did produce and continue for more than two years a most distressing affection of the nares.
2. Indirectly this exophoria caused loss of smell, tinnitus aurium and deafness, with great nervous prostration.
3. In one such case the correction of the exophoria by prisms aggregating twelve degrees produced immediate relief which has continued during two months and more.[1] It also indirectly cured the tinnitus, increased the hearing, and the sense of smell.
4. There is no reason to deny that in another case the disturbance induced in the nerve centres by an exophoria, may not attack other organs or apparatuses, and induce in them effects similar to those we have seen induced in the nares and adjacent structures.

AN OPERATION FOR THE RADICAL CURE OF STRICTURE OF THE LACHRYMAL DUCT, WITH DESCRIPTION OF A STRICTUROTOME.

Read in the Section of *Ophthalmology* at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CHARLES HERMON THOMAS, M.D.,
OF PHILADELPHIA.

All those who have busied themselves with the surgery of the lachrymal passages must be aware that surgeons have not agreed upon a satisfactory method for the treatment of stricture of the lachrymal duct. With respect to the possibility of radical cure, the attitude of many is one of discouragement, perhaps even of disgust. Of all procedures in use, none is so generally employed as dilation by probes. But the length of time which this method of treatment requires, the amount of trouble it involves, together with the uncertainty of permanent good results, all of which its adherents admit, make it very desirable that some more effective procedure be adopted.

---

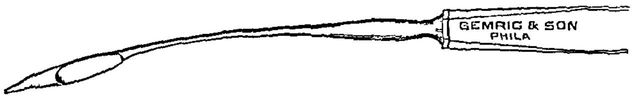
[1] Sept. 1, 1892.—As this article was being corrected, an examination of the case showed a continuance of the improvement described; this covering a period of nearly six months.

Influenced by the results obtained by French surgeons in internal urethrotomy, Dr. Stilling, then of Hesse-Cassel, published a brochure in 1868,[1] detailing a new method of treating stricture of the lachrymal passages by internal incision, an operation devised by him and which he was the first to make effective. My attention was at once attracted to this paper. The operation strongly appealed to me as a promising one, and correct in principle.

But I believed that the instrument which he proposed was not altogether well adapted to the purpose for which it was intended. In the first place, the knife being short, straight and rigid, is not readily applicable to the bony canal, entrance to which, moreover, is more or less impeded by the overhanging brow, an obstacle which all who have attempted to pass a straight Bowman's probe have doubtless encountered. Then the rounded cutting point and tapering blade, broadest where it joins the shank, make an instrument which one might naturally shrink from introducing into such a passage.

To meet these apparent objections, I devised an instrument which was made for me by J. H. Gemrig & Son in August, 1869, and which has been subjected to the test of use in my own hands, and some others, during the more than twenty-two years which have followed. The results have been so wholly satisfactory as to lead me to welcome the invitation of the Chairman to present the subject here; especially as I have delayed publishing any account of the matter till now.

The instrument consists, besides the handle, of shank, blade, and tip. Its length, exclusive of the handle, is 5½ centimeters. The shank is of untempered steel, to give it flexibility, and is 4 centimeters in length. The flexibility of the shank is such as to permit the instrument to be bent into any curve found convenient for introduction into the canal and its length such that in operating the handle does not descend below the level of the brow. The cutting blade is 7 millimeters in length and 3 millimeters in width, the whole terminating in a conical tip, blunt at the point, and equal to the blade in length, thus forming a probe, dilator and knife combined. The conical tip serves at once as a guide and a dilator for the cutting blade which follows, and also as a protector of the soft parts during the introduction and withdrawal of the instrument. A considerable experience in urethral surgery, and especially in internal urethrotomy on my own part, had prepared me to regard Stilling's insistence on the analogy between stricture of the urethra and of the lachrymal passages as in the main justifiable; and, I may add, as a false passage in the surgery of the urethra is, under all circumstances, to be sedulously avoided, so in the treatment of lachrymal stricture, like considerations are applicable, and like care is to be exercised. And as in operation for stricture of the urethra by internal urethrotomy incision is properly preceded by dilatation, not as a method of cure, but as a necessary preliminary to the entrance of the cutting instrument into the lumen of the canal, so in incision of coarctations of the lachrymal passages, like precautions should be taken, allowance being made for the difference of structure in the two cases.



From this point of view Stilling's knife appears to be defective; there is no certainty that its rounded cutting-end will enter the narrowed lumen of the duct, and that the downward thrust may not carry it through the tissues alongside of the true passage, and thus force a false one. And a false passage once made, the subsequent incisions taking their start therefrom, may result in the formation of a canal whose wall being devoid of mucous membrane, shall consist of cicatricial tissue throughout. This danger is obviated by the conical tip of the stricturotome here described, serving, as it does, to guide the blade safely into the lumen of the duct, and to dilate the strictured part, so as to allow of the blade's easy passage through and beyond it.

From the foregoing it is clear that, while the initial incision with the Stilling knife is necessarily made as a thrust with a cutting pointed instrument without a guide and is, therefore, to a considerable extent a chance thrust in the dark, the incision with the stricturotome here proposed is a draw-cut from beyond the stricture upward and through it. The incision in the latter case is made at a definite point of selection, the seat of the stricture, and the instrument is at all times under perfect control and ready to be used either as an exploring, dilating or cutting instrument, as the exigencies of the operation may require.

In operating, the first step consists in slitting the canaliculus, the lower if a style is to be used, otherwise the upper. This is accomplished more conveniently with a small grooved director and Beer's knife than with Weber's knife. In making this incision, two points are to be observed: the cut is to be made along the inner edge of the lid, the edge of the knife being directed somewhat backward and toward the eye, so that the groove formed may be in a favorable position to receive the tears; and the opening into the sac must be made sufficiently large to permit the free entrance of the necessary instruments. This latter may be best accomplished with the point of the knife, before the director is withdrawn. An obstructing ledge of tissue is usually found at the inner end of the groove, formed from the lower canaliculus, which offers an impediment to the passage of instruments, and even of tears. This obstruction may be divided later by the stricturotome, during its withdrawal at the close of the operation.

A Bowman's probe, or better still, the flexible probe of Dr. Williams, of Boston, is now to be inserted to explore the canal, and to note the location and calibre of the first stricture encountered. The probe being withdrawn, the stricturotome, well oiled, is introduced, special care being taken to place the point of the instrument within the grasp of the stricture. Strictures impermeable to ordinary probes, and which allow only the passage of an Anel's probe, will be found permeable to the conical tip of this instrument. The tip being engaged in the stricture, gentle continuous pressure is to be made, and the cone carried through and beyond the coarctation. It cannot be too strongly insisted upon that exploration of strictures in this locality is to be conducted with extreme deliberation and patience; all instruments should be introduced by coaxing, and not by force. More than one sitting may be necessary to complete the exploration. The blade having been passed into the free space beyond the stricture, incision is made by a drawing movement upward, completely dividing the tissues at the strictured point, even to the bone, and in at least two different directions. The instrument should then be moved laterally in all directions, to make sure that no narrowing remains; and before withdrawal it should be carried within the nasal fossa as an exploring instrument, to learn if any other stricture be present, and which if found, should also be incised. By far the most common seat of stricture of these passages is at the junction of the sac and duct; only occasionally will a stricture be found at the nasal extremity of the duct. A little bleeding at the nose and at the inner canthus are the only external indications that an operation has been performed. The whole operation is singularly free from pain, and with cocaine the pain becomes quite insignificant.

---

[1] Ueber die Heilung der Verengerungen der Thranenwege mittelst der Innern Incision. Cassel, 1868.

Stilling, and those who have used his instrument, describe more or less considerable hæmorrhage from the nose and ecchymosis of the lower lid as the ordinary results of operation, due, no doubt, to the somewhat extensive and unnecessary cutting of healthy structures, which unavoidably attends the use of such a knife as his, but which conditions do not exist in the operation as here described, the incision here being limited to the parts affected.

As regards after treatment, I have usually introduced a large leaden style, measuring 8 to 10 millimeters in circumference with the upper extremity bent at a right angle, and so reduced in size as to drop into the open groove formed of the divided lower canaliculus, where it lies concealed. This is removed at first every day or two while the passage is washed; after the first ten days it need not be disturbed for a week or more at a time. At the end of a few weeks the style may be removed altogether.

Stilling insists that all after treatment, looking to the mechanical separation of the parts with a view to preserving the space gained by the incision, is not only needless but even harmful, in consequence of the subsequent inflammation said to be thus produced; and he therefore discountenances the use of either probes or styles under such circumstances. With this conclusion, however, my experience does not agree, provided that not a vestige of the stricture remains uncut, and that the passage be so large that the style goes loosely into place. Under these circumstances I have found that the style at least does no harm, while in some instances, where the parts are swollen and the cut surfaces are thus kept in apposition within the bony canal, it is likely to prove effective in keeping the several parts asunder. With patients who cannot be under frequent observation, this may prove an important safeguard.

When the style has been removed after several week's wear, and when on replacing it after an interval of a week or two, it is found to pass without impediment, we are safe in declaring that a cure has been effected. Experience in after treatment both with and without the style, leads me to believe that while success is likely to attend both methods, the use of the style, under the conditions noted, is, on the whole, to be preferred.

Although Stilling's operation has been noticed by writers of good reputation in Ophthalmology, from the time it was first introduced to the present day, it appears to have failed so far as England and America, at least, are concerned, to receive the general acceptance which its early promise and its great merits deserve.* Thus, while Soelberg Wells and R. Brudenell Carter both called attention to it — though without definite commendation—in the year following its introduction, Swanzy, in a recent edition of his "Hand Book", after describing the operation, says: "This method has never gained much popularity"; and Berry, in his "Diseases of the Eye", ignores it altogether. To these may be added in this country de Schweinitz, in whose recent work it is accorded scarcely more than a passing mention.

The chief reason of this indifference is probably to be found in the unmechanical and even formidable character of the knife which Stilling figured. Beside this, it was difficult for surgeons to adopt what appeared to be extreme views as to the necessity of abstaining from all after treatment, and upon which he strongly insisted.

The instrument here presented, in connection with the plan of after treatment recommended, is designed to meet these objections. If I shall succeed in getting thorough trial for the operation with the modifications here outlined, from the members of this Section, I am confident that it will, with you at least, supplant the use of probes, and take its place as the most useful and satisfactory method known for the treatment of an affection at times dangerous to the integrity of the eye and often annoying to both patient and surgeon.

As regards those cases in which operation within the duct is determined upon, there is practically but one method now in general use with which a comparison with stricturotomy can be made, and that is the treatment by slow dilation through probing. As between stricturotomy and probing, the superiority of stricturotomy will, I believe, be manifest to anyone who will make trial of the two methods. Stricturotomy promises immediate relief and radical cure, while probing is tedious, painful, usually dilatory, and often finally, ineffectual.

Weber's canaliculus knife, somewhat modified, has also been used for the incision of coarctations situated within the duct. At least two American surgeons have so employed it with the addition of a long shank. While this shank is unquestionably an improvement, if the knife is to be used within the duct at all, in my judgment, this knife, even so modified, is hardly less objectionable than the original Stilling knife. The probe point, in these instruments, as I have seen them, appears to be inadequate to serve either as an efficient guide or dilator and if in use it should fail to engage properly within the lumen of the duct, and a false passage is produced, the result will be a lacerated instead of an incised wound, which latter at least would be made by Stilling's knife under similar circumstances.

---

*The same appears to be the case in France. Since my article was written, a paper in the "Recueil d'Ophthalmologie" for May, 1892, by Dr. Chouvel, surgeon-in-chief of the French army, gives the result in fifty cases of lachrymal obstruction by probing. He concludes as follows: "It has seemed to us that it is not without utility to make known the little success which slow and progressive dilatation has yielded in our hands, seeing that this method of treatment is the one which thus far has the most adherents."

Stricturotomy is, of course, not recommended for every case of epiphora, nor yet for all cases of dacryocystitis. In this connection should be mentioned the simple and ingenious suggestion of Dr. George M. Gould, of Philadelphia, who reports[2] having obtained good results through a method by which the patient himself is enabled to wash out the tract with an antiseptic or astringent lotion, with the intervention of a syringe. I have adopted this method in one case with strikingly good results, and believe that in certain cases it may properly supplement, and in others, supplant, operative or other treatment.

As long ago as 1867.Stellwag[3] called attention to the causal relation between disease of the nasal fossæ and antrum and of affections of the lachrymal passage, and advises general and local treatment of any morbid condition found, such as ozena, polypi, or other new growth within the nose or antrum, chronic *inflammation of the Schneiderian membrane, etc.*, and quite recently, good results have been reported by de Schweinitz[4] in epiphora by a systematic examination and treatment of the naso-pharynx. When all has been done however, that can be effected by the rhinologist, a considerable proportion of cases will doubtless remain, which will continue to demand the services of the ophthalmologist.

I quote the following from R. Brudenell Carter written in 1869,[5] calling attention to Stilling's method, and depicting the state of the art at that period: "It is well known that lachrymal obstructions depending upon strictures of the nasal duct, below the sac, are often of a very obstinate character. In some cases, when the canaliculus has been slit up, and Bowman's largest probe passed through the stricture, the difficulty is soon overcome. In others, and I think they form a majority, the stricture soon closes again, and the malady becomes as troublesome as ever. All manner of devices have been tried in vain; and such patients become a source of unmixed weariness at the hospital, and of weariness, mitigated by guineas, in the consulting room. Catgut probes, laminaria probes, injections of all sorts and in all quantities, styles to be worn temporarily, styles to be worn permanently, form only a few of the resources that have been tried, sometimes successfully, but yet with frequent failure, even in skilful and practiced hands. And, if these probings and manipulations were ever performed unskilfully, it could scarcely be expected that benefit would be derived from them."

This somewhat picturesque statement has additional interest, serving to bring home to us as it does, how little progress has been made since that time. Besides, Berry,[6] in his work, thus expresses himself:

"When a stricture exists at the orifice between the sac and the duct, the patient may, after it has been dilated, be taught to pass the probe himself, or, as recently been suggested, and practiced by Benson, he may introduce pewter styles every night, removing them again in the morning. By prolonged treatment of this nature, more or less improvement is generally eventually obtained, but there are always some cases in which this is not the case; in such it is necessary to have recourse to destruction of the sac altogether. . . . . An attempt may always be made to dilate the stricture by the introduction of the probes at intervals of a few days, or by causing the patient to wear styles, but the results are often unsatisfactory; fortunately such cases are comparatively rare."

The following case, from a series reported by Warlemont,[7] may be taken as typical, and well illustrates the striking contrast between treatment by probing and that by stricturotomy.

Mathilde D., æt. 20, has suffered for several years from epiphere of the left eye, for which she was treated by catheterization by Bowman's probes for more than three years (sic). A stricture was found at the upper extremity of the nasal duct, and another at its lower end; probe No. 4 was passed into the nose, but not without difficulty. For the last three years, this young and pretty girl, with a constancy worthy of a better lot, has come once or twice a week to have *the sound passed; the tearing persists, and mucous* shreds are seen to escape from the upper punctum, long since incised, on making somewhat forcible pressure over the sac. In short, the cure threatens to be long delayed.

June 4. Stilling's operation. Incision of strictures made with the greatest care. Nasal hæmorrhage.

June 10. The patient declares that she is better than she has been for three years; no more tearing nor accumulation of mucous in the sac. The slight conjunctivitis which has existed for a considerable length of time has disappeared.

Oct. The cure is complete, and has remained so for the five months she was under observation.

Within the past few days, it has been my good fortune to have an opportunity of examining the first patient upon whom I operated by this plan, now somewhat more than 22 years ago. This lady, who suffered from stricture of the duct, causing dacryocystitis and epiphora, has been perfectly well from the time of the operation to the present day. Pressure over the sac shows no trace of regurgitation, and a large Bowman's probe is readily passed without encountering the least indication of stricture.

Another case illustrating the serious consequences which occasionally follow from lachrymal disease, and the excellent results obtained by stricturotomy, is that of a gentleman from Virginia, sent to me by Dr. Conger, of Oswego Co., New York. He had been under treatment by specialists in three of the principal cities of the country, and for periods varying from 3 to 6 months at a time. He had severe chronic conjunctivitis, dense pannus, with hardly more than light perception, the iris being totally concealed from view. The condition in both eyes was the same, so that he was quite blind and had to be led. He was a business man, and had been compelled to give up his business. After several months of varied but almost futile treatment, I still advised him to remain under further observation, with the hope that a clue might be found that would lead to his relief. During this time he was seen in consultation a number of times by my friend, the late Dr. R. J. Levis. The patient reported that he occasionally found yellowish "worm-like threads" in his eyes, especially on awaking in the morning. My attention having been attracted by this, I was one day led to make a more than ordinarily careful examination of the entire conjunctiva, when, on casually making pressure over the lachrymal sac, I observed a spurt of yellowish muco-pus issuing from both upper and lower puncta of both eyes, which led me to believe that I had found the source of the irritant upon which the disease depended. I slit up the lower canaliculi at once, and incised strictures found at the junction of the sac and duct. The good effect was manifest almost immediately. Within six weeks from the time of the operation, I received letters from him, written at his home, in his own handwriting, informing me that he had resumed business, and was able to read coarse print. It is worthy of note that there had been neither epiphora nor swelling in the region of the sac, nothing in fact to call attention to the lachrymal difficulty. I continued to hear from the patient up to the time of his death, which occurred some years later. The good results persisted; his visual acuity improved still further, and in short, he regarded himself as a well man.

In forming an estimate of the relative value of the two methods under consideration, it is to be observed that by both, a permanent enlargement of the calibre of the duct is the object sought to be attained. In both, increased calibre can be secured only by structural changes in the walls of the duct. But in each, totally different principles as well as procedures underlie the results aimed at. By the process of probing—gradual dilation—the change is sought to be effected through absorption of the tissues forming the stricture, by means of the pressure of the impinging probe, with a redisposition of new tissue elements to compensate for the increased size of the duct. Such a process is slow and tedious at the best, and finally uncertain in its results, and for these reasons practically unavailable. Stricturotomy, on the contrary, at once effects an enlargement of the canal, giving the reasonable expectation of its permanent patency. It may be added that while the canal, as produced by stricturotomy, may be larger than is necessary for the performance of the normal functions of the part, it is certain that the space provided by probing is usually altogether deficient in size. The larger size, in the one instance, however, does no harm, while the small size produced in the other results in the failure of the operation.

In the light of all the facts, I feel warranted in stating my belief that probing as a method of treatment should be discarded. And, also, that stricturotomy, as here described, based as it is upon sound surgical principles and supported by experience, should be substituted for it, and all other instrumental procedures now in use for the treatment of stricture of the lachrymal duct.

Lachrymal stricture treated by this method has, in my hands, during many years, yielded results as satisfactory as those following operation in other parts of the body.

CLOSURE OF THE LACHRYMAL PUNCTA IN DACRYOCYSTITIS AS A BARRIER AGAINST INFECTION OF THE WOUNDED EYEBALL.

Read in the Section of Ophthalmology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY G. A. ASCHMAN, B.Sc., M.D.,
WHEELING, W. VA.

That an unsound condition of the lachrymal sac and duct is a constant menace to the eyeball and, in fact, the most mischievous source of infection, is admitted by everyone familiar with the subject. The pernicious quality of the secretion in dacryocystitis is caused by the copious existence of microörganisms of many varieties, and with the exception of the gonococcus, none are known to be more hurtful to the tissues of the eye. The rule is therefore strictly observed, not to operate for cataract, etc., before any existing lachrymal trouble has been eliminated. Even the slightest corneal wound affords a favorable point of entrance for the virus, and hypopyum keratitis with all its dangers results. The striking fact has been proven that from 20 per cent. to 32 per cent. of the cases of hypopyum keratitis are complicated with dacryocystitis.[1]

As a rule, a person afflicted with some disease of the lachrymal apparatus passes many years of his life without any further annoyance than a constant overflow of tears, which necessitates the frequent use of his handkerchief, and a discharge of muco-purulent secretion, which causes a sticking-together of the lids in the morning. Then, by accident, some foreign body produces an abrasion of the corneal epithelium, and the opportunity for infection is given. At first the eye becomes injected and inflamed and a small yellow spot with ulceration forms at the site of injury. Frequently it is not made much of until pain supervenes, the violence of which induces the patient at last to seek medical aid after several days have elapsed. The physician, frequently overlooking the lachrymal trouble, prescribes cocaine and hot fomentations with some antiseptic wash—but the eye grows worse from day to day. While the ulcer increases in size a yellow precipitate forms at the bottom of the anterior chamber; and it is often only at this stage, after the hypopyum has developed, that the oculist is consulted. It has been my experience to see the great majority of cases for the first time from ten days to three weeks after the injury had been inflicted. Speedy action is now demanded. Sometimes it is still sufficient to thoroughly scrape the floor of the ulcer, dust it with iodoform and to frequently flush the eye with a 1 to 2,000 sublimate solution, to which the use of hot fomentations is added when there is much pain. Cauterization of the ulcer, however, usually proves more beneficial, and it is now generally admitted to be the best means of destroying the germs and bringing about absorption of the hypopyum. But even this will frequently not obviate the necessity of a paracentesis or a Sæmisch operation. Only after the pus has been evacuated and the necrotic tissue eliminated does healing often begin, and after several weeks the eye recovers with a more or less large leucoma. But there is still a number of cases (according to different statistics from 9.5 per cent. to 19.2 per cent.[2]) especially in old and debilitated persons, where, in spite of the above treatment, the ulcer increases, staphyloma forms or the whole cornea is ravaged, and suppuration extends to the interior of the globe. It has appeared to me that, while all these active measures are being directed against the pus in the eyeball, sufficient attention is not paid to the source of infection, viz., the lachrymal apparatus. All our efforts may be entirely neutralized as long as there is a chance of renewed entrance of infectious material. To be sure, it is generally advised to add treatment of the sac and tear duct, to slit the canaliculus according to Bowman's teachings, to pass the probe and syringe the duct with antiseptic lotions. But we all know how long it often takes to cure dacryocystitis, if it can be cured at all, and before this is accomplished and the last pus germ eliminated, the eye may be destroyed. Even though we freely open the tear sac, evacuate its contents and treat its surface with strong antiseptic solutions, the source of trouble may be further down in the duct, or even in the nose. The importance of attention to intra-nasal lesions in obstructive disease of the lachrymal apparatus has recently been emphasized by Dr. de Schweinitz[3] in a paper read before the Philadelphia County Medical Society. A number of cases are cited where intra-nasal treatment was necessary to cure the lachrymal trouble. But this also requires considerable time, whereas the infected corneal ulcer calls for speedy action. With regard to obliteration or excision of the lachrymal sac, it must be admitted that it would be the most efficient means of eliminating the virus. But it is quite a violent and painful operation, not to mention the time required for healing, so that the patient, now weak and debilitated by constant suffering, would hardly agree to submit to it. The question has, therefore, presented itself to me, if it were not feasible, after disinfecting all implicated parts in the best possible manner to quickly and effectually close the lachrymal puncta. Could this not be accomplished, at least temporarily, until the danger is over? Allow me to make my answer by shortly citing a few cases:

---

[1] Noyes, Diseases of the eye, page 366.
[2] Noyes, loc. cit.

Case 1.—Mr. W. V., 63 years old, farmer, ten or eleven days ago while cutting corn something, probably a particle of a blade of corn,got into his right eye. It pained him at once and he tried to rub it out. The same eyeball had been inflamed twice before but recovered in a few days. As then, he made cold wet applications during the night and felt better in the morning. But the following day the soreness returned and gradually grew worse. In spite of several home remedies the increased pain began to extend to the forehead, temple and right side of head. Noticing, after a week, that the eye had almost completely lost its vision, he came to Wheeling and consulted Dr. I. P. Birney. The doctor at once applied cocaine and antiseptics, telling him the eye was probably lost, and on the following day, October 6, 1891, sent him to me. I found an extensive infiltration of the central portion of the cornea, in the centre of which was a small wound covered with pus. About one-third of the anterior chamber was filled with hypopyum, and on pressure over the inner angle of the eye a large drop of thick muco-pus gushed from both puncta. The man was very feeble and debilitated, as he had suffered intensely and not slept for three nights and days. I first thoroughly flushed the conjunctival sac and eyeball with a corrosive sublimate solution 1 to 3,000 and tried to empty the lachrymal sac as much as possible by pressure. After the instillation of cocaine and atropine I introduced a fine Bowman probe through the lower canaliculus, without slitting the latter, and a stricture was detected about half-way down the duct. After thoroughly washing out the sac and duct, as far down as possible, with a pyoctanin solution 1 to 1,000 by means of Anel's syringe, I scraped the floor of the ulcer and dusted the whole with iodoform. The existing chronic nasal catarrh was properly attended to and the usual directions given for home treatment. The following day less pain was reported. but the ulcer and hypopyum had increased somewhat, so I cauterized the former extensively, after which, for the next two days, it seemed to get smaller and pain less severe. While the treatment of the sac was constantly continued the discharge became gradually of a less purulent and more mucous nature looking exactly like the white of an egg. The hypopyum did not diminish, however, and the patient still had some severe spells of neuralgia. So I decided to make a Sæmisch operation. After the aqueous had slowly flowed off I managed to remove the hypopyum with an iris forceps. But in spite of all antiseptic precautions the corneal wound did not close, and after two or three days I found a yellow infiltration of its edges and pus beginning again to accumulate in the anterior chamber. While I was preparing to cauterize the edges of the wound, it occurred to me to go further back towards the source of the trouble and see if I could ward off the lachrymal discharge by closing the puncta with the electro-cautery. After injecting cocaine, I pushed a fine wire about ⅛ of an inch through the puncta and closing the current, brought the point to a red heat, which after a few seconds was slowly withdrawn. My expectations were realized, as the resulting burn of the mucous lining brought about a firm adhesion of the walls of the canaliculus. That the connection between the lachrymal and the conjunctival sac was now entirely interrupted was proven the following morning, when I found a slight swelling over the site of the lachrymal sac, light pressure upon which did not drive any discharge through the puncta. The corneal wound had a better aspect and under antiseptic applications the beginning hypopyum disappeared in another day. Repair began and the eye rapidly mended, while, at the same time, the swelling of the lachrymal sac increased very slightly. A week afterwards, thinking the corneal wound sufficiently closed, I reopened the lower punctum with a pointed probe and evacuated the accumulated mucous. The patient left for home the following day in good spirits, not caring about any further treatment of the lachrymal duct and nose, which I had advised. I have since learned that in spite of a large leucoma, the eye has regained a small amount of vision.

Case 2.—A. H., 42 years old, of Kingwood, W. Va. February 6, 1892, he was working on his farm with a hoe, when his right eye began to pain him; but he does not remember having been wounded. The same evening inflammatory symptoms became worse, and pain and headache continued to increase from day to day. He was treated at home for two weeks, and then came to Wheeling, when he was at once referred to me by Dr. Ackerman. Diagnosis: Advanced hypopyum keratitis. Small corneal ulcer at the inner quadrant, and the anterior chamber at least half full of pus. Profuse purulent discharge from both puncta, which the patient said had existed for many years without giving him much trouble, as he had always been able to empty the sac by squeezing its contents into the nose. The same treatment was at once instituted as above, only that I was able to syringe the whole duct, the antiseptic fluid escaping from the nose. The following day both puncta were closed with the red-hot wire, and a Sæmisch operation performed, which entirely evacuated the pus. The eye began to recover at once without any accumulation of muco-pus in the sac, as the patient was directed to keep it empty by frequently squeezing the contents into the nose. During that time it was peculiar to notice an increase of discharge from the puncta of the other eye. After ten days I reopened the lower punctum, and the patient, anxious to return to work, left for home after a sojourn of a little over two weeks. The resulting corneal scar was comparatively small, and he promised to return soon for further treatment of the lachrymal trouble. His physician has recently written me that his eye is doing well, epiphora being noticed only at times.

Case 3.—M. M., 48 years old. While breaking limestone, he noticed that his right eye became painful, and the following day vision had considerably diminished. He was compelled to quit work, and, as the pain increased, he came to see me May 1, 1892, five days after the first symptoms. I found an ulcer in the centre of the cornea, with surrounding gray infiltration. Slight degree of dacryocystitis, but no hypopyum. I cauterized the ulcer with the hot wire, closed the lachrymal puncta, prescribed hot antiseptic compresses and atropine, and the eye was well in less than a week.

With regard to the means of interrupting the connection between the diseased lachrymal passages and the conjunctival sac, I remember having read the description of a clamp which would tightly compress the canaliculi. But I have not had sufficient faith to try it, considering that the pus cell will manage to creep through the smallest aperture. Prof. Eversbusch[4], of Erlangen, recently reported a method by which, in cases ready for cataract operation, where there was suspicion of a diseased condition of the lachrymal passages, he had closed both canaliculi with catgut ligatures. He declared thereby to have prevented all possibility of infection, which was proven by the good results obtained. The electrocaustic closure of the puncta, however, appears to be much simpler and surer.

[4] "Ueber die Anwendung der Antiseptica in der Augenheilkunde," Centralblatt fur Augenheilkunde, December, 1890, p. 354.

Shortly after discharging Case 1, I found in the *Centralblatt für Augenheilkunde* the review of an article by Prof. Haab,[5] of Zurich, in which he describes a procedure of closing the lachrymal puncta with the galvano-cautery, to prevent infection, before operating for cataract. His examination of cataract patients is completed in all cases by syringing the lachrymal passages, and whenever the slightest narrowing or discharge is detected, he closes the puncta with the electro-cautery the day before the operation. This, together with other proper antiseptic precautions, has enabled him during the past few years to remove a number of cataracts in spite of the presence of dacryo-stenosis, with excellent results. In fact, he declares that this complication, which is generally regarded as a *noli me tangere*, has now lost for him all its dangers. As I have a case of almost mature cataract, where the other eye was lost by suppuration after operation performed by another surgeon, no doubt resulting from still existing dacryocystitis, I intend trying this method, with the consent of the patient. Safety will be enhanced by postponing the extraction a day or two, until complete obstruction of the puncta is surely demonstrated. It would certainly be a benefaction not to be obliged to refuse such persons an operation, thereby condemning them to permanent blindness.

TREATMENT OF KERATOCONUS BY MEANS OF THE GALVANO-CAUTERY AND IRIDECTOMY.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY ROBERT D. GIBSON, M.D.,
OF YOUNGSTOWN, O.

My object in presenting this subject is to get more light.

I have been unable to find any literature upon the subject which gives anything encouraging in the way of treatment.

In October, 1890, while a student under Dr. Knapp in the New York Ophthalmic and Aural Institute, it was my fortune to witness him treat a single case, with small central opacity, by paracentesis with the galvano-cautery needle. I did not see or learn of the results in Dr. Knapp's case, but accepted it as *theoretically* the most likely to give good results, and have tried it in two cases, the results of which I beg to submit for the basis of discussion.

As no definite results are reported, I have nothing with which to compare my results, but trust that they are at least worthy of consideration.

The literature on keratoconus is meager and widely scattered, so that it would be wellnigh impossible to present an acceptable review of the subject, upon which to base our remarks.

As to the cause of the disease we know but little or nothing, except that for a period ranging from a few months to a few years previous to the time vision began to fail, there is a considerable lowering of the vital energies from some cause or other.

As to the exact bearing this would have on the cornea, it cannot be definitely shown, but doubtless the condition present would be analogous to that which in some other person would terminate in ulceration of the cornea (either superficial or interstitial).

The tension is not increased in the least, but on the contrary, it is diminished. In case the tension were increased the curvature of the cornea would be lessened, that is, the eyeball would become a more perfect sphere, and the cornea would no longer maintain the curve of a sphere having a shorter diameter than that of the eyeball. If increasing the tension will produce less curvature of the cornea, surely a subnormal tension must be present to *admit of* increased curvature. And upon examination the tension is found to be subnormal.

The course of the disease is usually slow; the first manifestation being failing distant vision. As the disease progresses there is greater impairment of vision, and in case there is interstitial degeneration the cornea will become hazy, and vision will be reduced to perception of light. The first manifestation of interstitial degeneration may be seen by means of strong oblique illumination (using a large lens). Fine lines may be seen at the apex of the cone, which resemble the lines on crazed glass; these lines increase in number and coalesce till they present the appearance of extensive interstitial ulceration.

This ulceration seems to be confined to the "*substantia propria*" and possibly the anterior "basal membrane," or what is known as the "scleral division" of the cornea, but cases have been reported where the cornea became so thin that they ruptured spontaneously.

The diagnosis in the early stage may be made by means of the ophthalmoscope or Placido's disc. With the ophthalmoscope the optic disc seems kite-shaped, as are also the rings of Placido's disc as seen reflected from the cornea. The parallactic movements may be seen by moving either the head or objective lens. In the advanced stages, the deformity of the cornea is quite noticeable. The full front view of the eye presents a clear, watery appearance, due to the deep anterior chamber and the reflection of light from the surface. The profile view is similar to a cone, therefore the name keratoconus.

During the past six months it has been my privilege to have two cases (three eyes) of keratoconus under my observation.

The first is still clear, though the deformity is quite noticeable and vision is reduced to $\frac{2}{200}$.

The history is: Mrs. U., æt. 22 years, at 15 years of age was thrown out of a carriage on to the road by a runaway team, struck the right side of the face on the ground, both arms were broken, and was otherwise injured so that she was confined to bed for three months. After getting out she noticed the vision of the right eye was failing, and it has resulted in keratoconus.

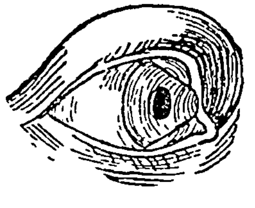

FIG. 1.

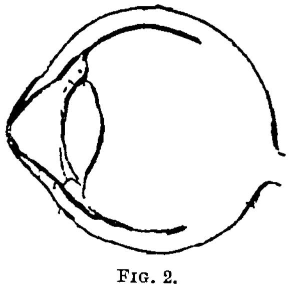

FIG. 2.

The second patient had double keratoconus. The right eye presented a very unfavorable appearance; the cornea protruded to the full extent possible (Figs. 1 and 2), the opacity extended on all sides of the apex so as to completely cover the pupil, the central portion of the cornea was extremely thin (Fig. 2), and vision was reduced to perception of light only.

---

[5] Bemerkungen zur Staar Operation, November and December, 1891.

The left eye presented the deformity to the same degree, but was still clear. By strong oblique illumination interstitial degeneration could be determined by the prèsence of two or three fine lines, at the apex. Vision was 4-200. Her history is as follows:

Miss Sarah S., æt. 22, farmer's daughter, came to my office December 21, 1891. General health not very good; has been ailing since 16 years of age; menstruation irregular, varying from six weeks to sixteen months. Eyes began to fail at about 17 years of age; both failed alike, till a few weeks ago the right "seemed to go all at once."

On account of the failing condition of the left eye, and the fact that the right eye was already useless, it was thought best to operate on the right eye at once (December 21, 1891). Paracentesis of the cornea was performed at the central point with the galvano-cautery needle. The central portion of the cornea was so thin that it wrinkled up or collapsed as the anterior chamber was evacuated. The eye was opened but once each day for inspection. At the end of eight days (December 29) the opening had closed. The cornea had receded about halfway back to the normal curve. The eye was again cocainized and a slightly larger opening made at the same point with the galvano-cautery needle. Kept the eye closely bandaged and patient in bed for eighteen days, inspected the eye once each day, and at the end of eighteen days the opening had entirely closed and the cornea had receded to the normal curve (Fig. 3). The extensive opacity was largely absorbed, but a central opacity nearly the size of the pupil still remained after two months. There was very good vision excepting in a bright light, when the pupil would contract. She could see to read the headlines of the newspapers, and tell the time on my watch to the exact minute. V. equals 20-100. March 18, 1892, an iridectomy was made, inward and slightly downward (Fig. 4), resulting in vision 20-50 +, with + 5 .50 D. cyl. axis 15°. The fact that a *plus* 5 .50 D. glass is accepted would indicate that the cornea must have receded to, if not beyond, its normal position.

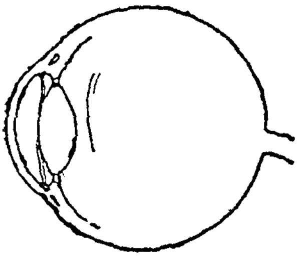

FIG. 3.

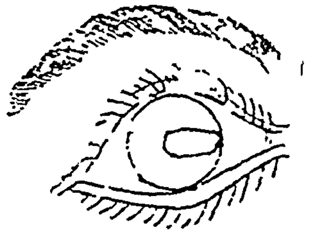

FIG. 4.

The vision of the left eye, in the meantime, was failing on account of the central opacity increasing. It was thought best not to wait till the opacity would become so extensive as in the right eye, therefore the eye was treated after the same manner, and with nearly as good results, as the right eye. V. equals 20-50 —, with — 8.00 D. sph. ⊃ — 3.00 D. cyl. axis 120°. The cornea of the left eye had not become perceptibly thinner than the normal, therefore presented greater resistance to the compress and contraction, and resulted in less correction of the deformity than in the right eye. The result is so good, however, that I hesitate to continue further treatment, but am quite confident that by repeating the puncture once, or possibly twice more, we would be able to get rid of the concave spherical lens.

By making the opening at the central point of the cornea there is no danger of prolapse of the iris.

The advantages of making paracentesis with the galvano-cautery needle are:

1. Perfect antisepsis or asepsis.
2. Prolonged drainage of the anterior chamber.
3. The resulting opacity is reduced to a minimum.
4. There is doubtless some shrinkage of the cicatrix, which would tend to reduce the curvature of the cornea somewhat.

The advisability of performing iridectomy must be governed by the extent of the opacity. I am quite well satisfied that the operation for iridectomy in these two eyes had very little, if any, effect on the curvature of the cornea, and might have been dispensed with, except from the fact that the opacities present before performing paracentesis with the galvano-cautery needle, were large enough to materially interfere with useful vision.

Discussion.

Dr. Henry D. Noyes, New York:—I have been interested in conical cornea for many years and have examined many cases. In the first place the projection of the cornea is often not central. It more frequently is below the horizontal meridian. This is chiefly due to the pressure of the eyelids.

The essential pathology of this condition is that it is not due to intra-ocular tension, but is a process of atrophy of the cornea, and protrusion takes under the normal prèssure. This is aggravated by the action of the lids.

Furthermore, these cases, while in a general sense myopic, are susceptible of amelioration in the early stages by glasses of a peculiar character. The glasses best suited are generally convex cylinders. A mixed cylinder with axis at a right angle will often answer well. Examination for astigmatism by the ordinary methods is exceedingly unsatisfactory. There is no use of giving atropia, because in this way you expose a larger surface. The best way is by the stenopaic slit and the method of Thompson who uses two lights and a disk with a little perforation. Then the ophthalmometer comes into play to show the curve of the cornea.

There is still another fact. I labored for a long time over a patient and finally found a glass that gave satisfactory vision. She wore it for a day or two and then rejected it. She finally selected at an opticians a concave cylinder which differed from all examinations and wore that glass with comfort. Hence we must sometimes work by rule of thumb for such patients.

Bowman pointed out the irregular curve of the cornea and many of its phenomena. When the suggestion of using hyperboloid lenses was made by Rachlman, I tried them in a number of instances. Although hypothetically these cases should assume a curve which is some form of a hyperbola, they quickly depart from the hyperbola. The hyperbolic lenses did not answer in my experience, but others have been more fortunate.

In regard to the possibility of the rupture of conical cornea, this is one of the rarest of accidents. Many years ago I saw a conical cornea, three-fourths of an inch long, in a woman from St. Louis.

The surgical treatment is a matter of history from an early period. Graefe was the first to try to cure these surgically. He employed nitrate of silver and paracentesis. The galvano-cautery is classical in the books. It is a well-recognized method of dealing with this affection.

Excision of a piece of the cornea has been resorted to. I did it once. I found that I could excise a flap and put in sutures as in a plastic operation on the skin. The patient recovered with good vision. I do not know that I shall ever do it again. I had a set of Dr. Williams' needles. I left the sutures in three days. I should have removed them in two days, and the fistula that occurred and continued a few days would probably not have formed.

There is an optical phenomena in conical cornea to which I may refer. If you take a cornea with a considerable amount of conicity and illuminate the eye by a convex lens normal to the axis of the eye and station yourself on the temporal side at right angles, you will get a reflex from the back of the cornea coming into your own eye. This is the result of total reflection from its posterior surface.

Dr. H. Knapp, New York:—Dr. Gibson mentioned that he did not see the result of the operation. That case turned out very well. The patient made a long recovery and for six weeks there was constant breaking of the cauterized portion. I was in dread that suppuration would occur. The opening closed permanently leaving a scar somewhat below the centre of the cornea. In the second month after closure the sight was poor, but in the course of six or eight months the cornea flattened so that there was exceedingly satisfactory vision. I operated subsequently on his second eye and to avoid the long healing, thought that I would make the paracentesis of the cornea smaller. I cauterized a small portion and then pierced the center with the ordinary cautery. Only a drop of aqueous escaped. That wound closed soon enough and did not reopen. The operation, which was rather prolonged, was followed by iritis of a peculiar kind and about three weeks later, I saw in the lower part where the heat had acted most intensely, a yellowish substance which was inexplicable to me. It was not pus. The iritis continued for six weeks or two months, and I feared the occurrence of sympathetic ophthalmia. The mother of the patient, said to me one day "the best of bad things is that what we fear, commonly does not occur." I thought that this was a word of comfort which I might take for my further guidance. This yellow spot developed into a cataract, which I removed later, and the sight, with glasses, was perfect. The curvature of the cornea had become normal. That was three years ago, and the boy is able to use his eyes without trouble. He is a student at Yale College.

The next case I operated on with a galvano-cautery electrode which I had made for the purpose to avoid its prolonged application, for I was afraid that the cataract in the other case might have been caused by the heat. There had been nothing else to cause the cataract. The new electrode, which had an oval end plate, I applied a little below the centre of the cornea, simply turned on the current and cauterized to the depth that I wished. I pierced the place with a pointed tip. The opening closed in five or six weeks. Recovery was good and the result satisfactory.

In the third case I pursued the same method. This was followed by prolapse and iritis. The perforation and the ulceration resulting from it were opposite the lower part of the pupil, and the iris became attached to the cornea. I think that in this case, iridectomy will be advisable.

In two other cases, I operated with the same electrode without piercing the cornea. They have been completely satisfactory, and gave me no anxiety from slow healing or suppuration. The cornea flattened at once, but bulged again when the ulcers had healed. I cauterized again at the same place. Recovery good; corneal curvature normal. Sight excellent, viz.: 20-30 in one, the other not yet finally tested.

All these patients had their far point at one inch. They can read now from nine or twelve inches without glasses.

From my experience I am inclined to consider this as the best method with which I am acquainted—that is, the galvano-cautery without perforation, and if the flattening of the cornea is not sufficient, a repetition of the operation.

Dr. Edward Jackson, Philadelphia:—I think that Dr. Gibson's reasoning in regard to the mechanism of conical cornea is a little defective. If the membranes were uniform in their power of resistance throughout, the influence of tension increased or decreased would be to cause flattening of the cornea. I think, as said by Dr. Noyes, that the central fact in conical cornea is thinning and atrophy of a portion of the cornea, not always in the exact centre, but usually removed a considerable distance from the vascular supply, from the corneal margin. Still, I agree with the author that the tension is usually low, but I do not think the diminished tension is essential to the increase of the curvature.

In reference to the optical correction of conical cornea, the central fact is that the refraction varies from point to point in the cornea. Only in small areas is it uniform. Only a small area will be corrected by any one glass. Of course the glass given must be the one that corrects the portion of the cornea opposite the pupil when it is considerably contracted in near work, or in a bright light. We must select the glass for a small pupil. Dr. Wallace, of Philadelphia, has suggested the use of eserine or pilocarpine; and they can be used with advantage, to find the glass adapted to conical cornea, because they reduce the pupil to the condition in which it will be in near work. I have found more satisfaction from placing the patient in a bright light and making the test at the ordinary distance. In getting at somewhere near the proper glass, retinoscopy is valuable. By it you can make a general survey of the pupil, and select that part which is exposed when the pupil is contracted and has the most uniform refraction, and then choose the glasses to correct that portion, to be confirmed by the subjective test.

Dr. Julian J. Chisolm, Baltimore:—As far back as 1881, I reported my first case of cautery operation for keratoconus. I have performed the operation frequently. In my experience, the larger the needle and the larger the opening made in the cornea, the longer it takes to close, but the more flattening is secured and the better final results obtained.

As to irregularity in the acceptance of glasses for keratoconus, this is a well recognized fact. Sometimes cylinders selected at random give the best results. As strong as 10. + D. + cylinders at an accidentally discovered angle have been selected by a patient as giving the best vision. I have also observed that often the best result was secured through the stenopaic perforation. For some years I have used daily the eserine drop, because the shrunken pupil gave much better vision than the most carefully selected glasses. Half a grain of eserine to the ounce of water, instilled daily into the eyes by the patients themselves, often gives more comfort than glasses.

Dr. G. C. Savage, Nashville:—As to the early diagnosis, I learned eight years ago, while in the Royal Ophthalmic Hospital of London, that with the retinoscope we could detect a beginning keratoconus. I have not seen this referred to in any book. Seated as we usually are in using the retinoscope, and moving the mirror from right to left and up and down, and deflecting the light with or against the movement of the mirror, you will find that if there is slight conicity, the light makes a circular movement. In this way I have often determined its presence and been able to adopt measures for the prevention of further development.

Dr. Robert D. Gibson, Youngstown, O.:—I am glad to have had the opportunity of listening to this liberal discussion. In our literature on this subject no *definite* results are given, and there is nothing with which to compare results. The results are stated as "satisfactory." I should like to know the *exact vision* obtained. To say that we have had "good results," without giving the exact vision, is rather indefinite.

Whether the atrophy of the membranes is a cause or an effect of the deformity, I am unable to state. If it is the *cause*, what are the evidences to support the theory? I merely mentioned it as one of the conditions present.

RESECTION OF THE OPTICO-CILIARY NERVES.

Read in the Section on Ophthalmology at the Forty-third Annual meeting of the American Medical Association, held at Detroit, June, 1892.

BY JULIAN J. CHISOLM, M.D.,
OF BALTIMORE, MARYLAND.

This operation, which is so valuable in many cases, seems to have been abandoned by some ophthalmic surgeons, without sufficient cause. That accidents follow any operation, even the most simple, is an every day occurrence; and in the nature of things must be occasionally looked for. Under careful manipulation, which every surgeon is expected to exercise, failures should become more rare, and therefore should be very seldom met with. Simple nerve section, as a surgical procedure is not always a radical method of relieving pain. Even when a considerable portion of a nerve has been excised, sensation has been in time regained, with a return of the suffering for which the operation had been undertaken. To this experience the ciliary nerves are not exempt; and yet they possess so many peculiar advantages for a successful section. Their location, so easy of access; their isolated surroundings; the small extent of incision required; the small amount of blood lost; the loose connective tissue in which the nerves are imbedded, permitting a considerable separation of the divided nerve ends by the accumulating blood pushing forward the eye-ball and forcing backward the socket tissues; then the displacing of the delicate ciliary nerve threads when pressure is made on the protruding eye-ball by a firmly tied bandage, are all most valuable considerations for securing a favorable result.

In nerve section, as usually undertaken, the nerve is either imbedded in a dense fibrous tissue, so that the separation of the cut ends must be very limited unless they are dissected away from each other; or the affected nerve traverses a bone, and therefore is difficult of access; or it accompanies a large vessel and is necessarily dangerous to divide unless isolated by a careful and often tedious dissection. The nerve attachments of the eye seem especially arranged for easy section. They are clustered together in a very isolated manner. For a long distance they traverse the central axis of an ample cone which is only filled by an unimportant cellular tissue. In the midst of this they can be easily, speedily and surely reached, without detriment to any important structures, if ordinary care is taken by the operator. The contiguous vessels are all small, consequently no serious hæmorrhage is to be feared. The very looseness of the fatty tissues upon which the eye rests facilitates the wide separation of the nerve ends, when the escape of blood from the divided vessels accumulates in the socket. This blood pressure so disarranges the free ends of these conducting threads that their readjustment is very improbable; and yet we know that this reunion does sometimes take place. This is the only accident that should follow this simple, safe, and useful operation.

I do not propose in this paper to give a detailed history of optico-ciliary neurotomy; nor the various methods adopted by surgeons to divide or resect these nerves. With such you are all familiar. My object is to give my own personal experience with this operation from the year 1879 when I first performed it. From that time I have used it annually, as proper cases offered, until my experience now covers eighty-one operations; a sufficiently large number to draw safe conclusions from. In my early practice I tried the various methods of muscle section to facilitate the exposure of the nerve. I soon found that they complicated needlessly the operative manual, and made a very tedious and serious operation of what should be a very speedy and simple one. When the muscles were tenotomized, and afterward sutured, the tension put upon the threads by the blood clot accumulating behind the eye-ball would often tear out the sutures, or so stretch them as to produce an ugly strabismus; an after result that is not satisfactory.

As I was performing this nerve section only for the relief of pain, I did not see the need of taking away a piece of the optic nerve; nor could I see what special advantage would ensue should I bring this nerve under observation while I was dividing it. Therefore at a very early date I abandoned all needless manipulation, and adopted the simplest way of finding the nerve, with the least disturbance of the eye attachments.

I found that the nerve could be easily reached through a conjunctival incision made at the inner or outer canthus, below or above, and parallel with the inner or outer rectus muscle. This method I have exclusively adopted for many years. It makes the the operation so easy to both surgeon and patient that it might be utilized in every case of a comparatively goodlooking, lost and painful eye, which would otherwise be condemned to enucleation. It was never intended by a neurotomy to replace. in all cases, the removal of injured eyes. The majority of lost and painful eyes are so disfigured by the accident, or by subsequent inflammation, that they are not worth preserving. There are still left in the list of lost eyes quite a number, so little deformed, that no one would willingly give them up, were they not the cause of constant suffering. It is for this class of eyes that the operation of neurotomy is so especially applicable.

My method of procedure is as follows: A general anæsthetic is always administered. I have used cocaine for socket operations, but it has never given, to either myself or the patient, the satisfaction expected. For neurotomies, which are quick operations, I use the bromide of ethyl, because of its prompt and evanescent action. After a very few full inspirations of the ethylized ether, during a period that does not exceed one minute of time, the patient is completely anæsthetized. The eye is then thoroughly washed by a chloride lotion. A speculum keeps the lids apart. A fold of conjunctiva is caught up by the forceps, and is cut across in such a way as to make a horizontal incision, which extends from the lower and inner border of the cornea to near the caruncula. It lies parallel with the lower border of the inner rectus muscle, and is but little more extended than the conjunctival incision for squint operations. The application of the points of the scissors in this orifice opens the capsule below the rectus muscle. An instrument terminating in two small hooks is passed into the depth of the wound, and planted well back in the sclerotic. By drawing upon this instrument the eyeball is rotated forcibly outward, which brings the optic nerve with its important ciliary nerve surroundings, within easy reach. The curved enucleation scissors is now introduced through the wound into the socket directly behind the eyeball. With its closed blades, playing the part of a probe, the resistant optic nerve cord is sought. When it is found, by drawing the scissors forward until the nerve escapes, then opening the blades widely, the optic nerve with its entire surroundings can be caught in the jaws of the instrument. The resistance made during the section is proof the nerve has been seized; and if the scissors have been properly manipulated it ensures the complete division of the entire bunch of nerve cords. As an evidence that this has been accomplished the closed scissors, used as a probe, can now move freely in all directions behind the eyeball without meeting any impediment. To secure this complete severance of the nerve bundle needs some familiarity with the resistance which the optic nerve makes to the section. The scissors must not be allowed to slide backward during the section, but the jaws of the instrument must be held firmly against the resisting body. The operation is now completed and the scissors are withdrawn.

In the minute necessary to perform the entire manipulation, blood has been pouring out of the divided ciliary vessels. It has been pushing the eyeball forward, and it has also been escaping from the wound. If this hæmorrhage be not at once stopped the eye would become exceedingly prominent, in forced exophthalmos, with quite enough tension to cloud the cornea and threaten its future safety. Without loss of time the speculum is withdrawn, and a large compress is firmly secured over the eye by a bandage. In one or two minutes consciousness returns, and the patient goes to his bed. As the after pains of the pressure bandage are annoying, a hypodermic of morphia is administered before the patient leaves the operating table. Pressure over the eye is kept up for several hours, or until all hæmorrhage from the divided vessels has ceased. This heavy compress is exchanged the next day for a simple dry dressing. Blood always infiltrates the conjunctiva and the lids, so that the surroundings of the eye are very much blackened from extravasation. It requires at least two or three weeks before this discoloration is altogether removed. The pains in the eye disappear promptly with the nerve section; and in my experience, permanent relief is usually secured.

The patient has had preserved to him a good-looking eye, that is worth all the risks of having the pain return to it at some future time, when the more radical operation of enucleation, if demanded, can be performed. Should this second operation not be required, he has been saved the constantly present thought of the mutilation which he has been subjected to, and which embitters his entire future life. He also escapes the daily annoyance of using an artificial eye, which gives a lot of trouble, as every wearer of one only too well knows.

Too many dangerously painful, but still good-looking, eyes have been ruthlessly enucleated, when this much to be preferred operation might have been substituted. I am fully aware of the many accidents which have occurred in the practice of ophthalmic surgeons—how hæmorrhage has been excessive; how dangerous and even fatal cellulitis has followed the exposure of the orbital tissues; how the cornea has sloughed; how the eyeball has in time become atrophic; and how endless troubles are engendered as the sequel of this operation. I will only say that in my experience no such accident has ever happened. I may have avoided many of them by using sterilized instruments; also by discarding at an early period the more serious exposure of the socket tissues by not doing myotomies, nor being desirous of bringing the optic nerve into view, so as to make the section, as it were, under the eye. I always felt that this bold, I am rather disposed to call it rash, dissection invited the serious accidents which afterward followed.

Unfortunately, I am not able to trace all of my cases. Several of them I have seen years after the nerve section. They had enjoyed life undisturbed by any return of pain. Others had promised to report promptly any returning discomfort. From these I have not heard, and therefore I presume that they have had no recurrence. In only four cases, coming to my knowledge, has it been necessary to resort at a later day to enucleation. There may be other cases in which this secondary operation may have been required. Had it been in many, I would certainly have heard of some of them.

In suitable cases of good-looking, lost, and painful eyes, I feel assured that neurotomy is far preferable to the mutilation of enucleation. I think that this statement will be accepted by all without a dissenting voice, if the dangers which some have encountered can be avoided. This can be in a measure secured by adopting the simpler operation, which in my experience is equally effective, when it is properly performed, as the more complicated ones, and with much less risk. It is also an operation which even the most timid patient will accept, when they would refuse to have an eyeball removed.

Notwithstanding the dangers ascribed to neurotomy, many of which are avoidable, I think that it would be well if surgeons who have discarded this good operation would again replace it on their list of available methods. Knowing its defects, and also being familiar with its advantages, were I required to make a choice between these two operations, enucleation or neurotomy, for a member of my own household, I would not hesitate an instant in the selection. I would accept the neurotomy.

114 West Franklin St., Baltimore, Md.

Discussion.

Dr. Eugene Smith, Detroit:—I regret that my experience does not correspond with that of Dr. Chisolm. I began the use of this operation in 1887-8, but soon stopped it. I had a pair of curved scissors made to fit around the posterior portion of the eye ball. I first began after the method of cutting the external muscle, and found the operation complicated. I then simplified the operation by making the incision beneath the external rectus muscle, and carrying the scissors behind the eye ball. The scissors hug the posterior surface of the eyeball very closely, and cause little mutilation. In no instance have I had an unfortunate result except the subsequent atrophy of the eye. There is a lady in this city on whom I operated at that time who wears an artificial eye. In almost every instance the eyeball has softened and generally atrophied to such an extent as to cause the patient to prefer an artificial eye, but it does make an elegant stump for an artificial eye. Since then I have abandoned the operation.

Dr. Samuel Risley, *Philadelphia*:—In what proportion of this large group of cases was the operation done for sympathetic ophthalmia? Were all the operations done for the relief of pain? This seems to me to be a very large number of eyes to be still painful, and yet present other conditions justifying optico-ciliary neurotomy. One of the most interesting and important causes for which it could be performed would be to save the eyeball in sympathetic irritation.

Dr. F. C. Hotz, Chicago:—I have never performed optico-ciliary neurotomy, and was therefore anxious to hear the paper in order to perhaps learn enough to induce me to perform it. I must confess that I am rather disappointed in my expectation, for if I understand the reader, his main indication for performing optico-ciliary neurotomy in place of enucleation is the painful condition of a good looking eye, where the eye is in such a condition as to make it worth preserving on cosmetic grounds. In the painful eyes that I have seen there has always been so much internal trouble that though the eye may have presented a pretty good appearance at the time, there was reason to expect that there would be a change in the appearance for the worse and therefore I have considered it better to enucleate at once.

Dr. S. C. Ayres, Cincinnati:—I would ask Dr. Chisolm whether the eyes on which he operates are blind from injury or inflammation? Does he enucleate the eyes that may become blind from any cause?

Dr. Julian J. Chisolm, Baltimore:—These neurotomies were designed for the protection of the patient, both from immediate suffering and the dangers of sympathetic trouble. The cases belong to both classes, those in which the sight has been lost from disease or by accident. We know that there are many wounds of the ciliary region afterwards accompanied by inflammatory trouble in which there is great danger. We find the patient suffering with pain, and we are not sure that sympathetic trouble may not follow. These eyes are often good looking. We know that if the patients could preserve their lost eyes without suffering, they would not seek any surgical interferrence. These eyes are often painful. I do know that in many of these instances where I have divided the nerve, a still good-looking, painless, anæsthetised eye is retained where otherwise it would be condemned to enucleation.

The operation is applicable to large numbers of eyes. Take that large class of absolute glaucoma. No one would be willing to give up a glaucomatous eye if they could painlessly keep it. These eyes are often very painful, the pupil enlarged and the lens cloudy. Should the pressure of the eye cause suffering, these should be cases for neurotomy in preference to enucleation.

Take another large class where the eye has been destroyed by choroido-iritis. We find still a comparatively good-looking eye which if it can be kept, is infinitely better than an artificial eye. If we can save to the individual such an eye by neurotomy, I contend that this is infinitely better than enucleation.

So far as atrophy is concerned, it has been my good fortune not to meet one such case, and I have seen many of these patients years after the operation. I have not been able to trace all of my neurotomies, so that I can not say that this result has not occurred. I am sure that those whom I have seen months or years after operation, with cornea still anæsthetic, a good looking eye with all its motions and discomfort, will not hesitate to say that neurotomy is a vast improvement on enucleation.

Acid Nitrate of Bismuth in Glycerine is a specific in microbic skin diseases.—*Curtman.*

MONOCULAR DIPLOPIA.

Read in the Section of Ophthalmology, at the Forty third Annual Meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

BY ROBERT TILLEY, M.D.,
OF CHICAGO, ILL.

In January 1888, I published a case of monocular diplopia. In order to avoid misapprehension, it may be well to state that the phase monocular diplopia is used to express the phenomenon, when there exists no visible anatomical peculiarity of the eyeball by which double images could be produced on the retina. Before narrating my own observation, I referred to similar cases published in the transactions of the Ophthalmological Society of the United Kingdom, giving particular attention to such cases as had been followed by an autopsy. At the last meeting of this society, Dr. J. H. Thompson, of Kansas City, brought the question before this Section, reported an interesting case and discovered the probable causes of the phenomenon. He referred to several other cases. Among others, one by Foutan reported to the Ophthalmological Congress, 1885, and accompanied by a very ingenious possible explanation of the phenomenon; and the case of Charlie Green, of St. Louis, reported separately by Dr. A. B. Shaw and Dr. Bremer, of St. Louis. This last case was especially interesting, inasmuch as it was followed by an autopsy but, very unfortunately, as far as I can understand was not well investigated from an ophthalmological standpoint:

When I reported my case in 1888, I supposed I should never see it again, but fortunately such was not the case. I will as briefly as possible recapitulate the history as then published and supplement its completion. A few years ago it was necessary to particularize accurately the details so as to show that there was no confusion between the phenomenon in question and an anatomically developed diplopia. Such minuteness is now scarcely necessary.

Mary R., 9 years, orphan, no family history obtainable; face expresses great distress, suppliant expression; step cautious as though afraid of jarring the head; eye (left) partially closed; movements of eye painful, no paralysis. severe pains in the head; slight conjunctivitis; cornea, aqueous; iris, lens, vitreous and fundus all normal; V. 6-18 with both eyes and each eye separately. N. V., S. O. 6; pupils contract normally both under the influence of light and accommodation. Persistently claims double vision in the left eye and denies it in the right. However the experiment was varied she never failed to sustain her claims and never contradicted herself. Under atropine the same answers were given to similar questions. Only now she claimed that for near vision one of the images was a good deal nearer to her than the other. For distant images this peculiarity did not appear or at any rate it was not demonstrated. She had no conception of any difference in color, between greens and greys; but a specimen of her work which I exhibit to you will give a better conception of her confusion of colors than any number of words (worsted work exhibited). This color blindness was in all probability of recent origin. These observations were made between November 12, 1887, and December 4, 1887.

December 4. She suffered from convulsions which came on in church and lasted for four hours. On the 8th, Dr. W. Brown, Professor of Nervous and Mental Diseases of Women's Medical College, was called in consultation. She had suffered from frequent delirium, excessive vomiting, buried her head in the pillow apparently from pain. She was, however, quiet enough at this time to demonstrate the diplopic phenomenon.

December 15. She improved rapidly without any manifest explanation, vomiting ceased, slept well, ate well. There was no mydriasis, no lack of accommodation, no paralysis. She still sees double with the left eye alone, the extra image is always in the nasal and upper half of field.

December 19. She left the institution in charge of the sisters and they reported that she seemed as well as ever but less active and less capable mentally.

January 19. As she did not return to the institution I visited her at her aunt's house. I found she was afflicted with abscesses in different parts of the body. The double images were still manifest to her left eye. My first report ended here. I did not expect to see her again but she returned to the sisters' charge and I had an opportunity of proving to myself that the diplopia had entirely disappeared and so had the color blindness. She sorted out the worsted skeins with a facility which left nothing to be desired. She remained with the sisters about twelve months and during that time although I was in constant attendance I never had occasions to see her except for my own gratification. About six months after her departure from the school the sisters reported to me that she was dead. There was no autopsy and I could get no reliable account of her last illness. The case presents these features of interest: Monocular diplopia confined to one eye, associated with severe cerebral disturbance and color blindness and recovery from both symptoms prior to death.

Since the observation of this case I have seen four others. All of them as clear and well defined relative to the diplopia as the one narrated:

Case 1.—Ilya H., 9 years, Swedish girl. There was a well defined monocular diplopia in both eyes, diminished visual acuity—6-18, deficiency of color sense. There was no manifest difficulty in the media or iridis and the fundus had a normal appearance. A month later she said her eyes annoyed her less and her vision was 6-9 nearly. Her mother did not bring her again. When I saw her later she reported that the child was quite well, did not complain of her eyes, but although she promised to let me see her she failed to do so.

Case 2.—F. M., 8 years, robust, strong, healthy looking girl was brought to my office by her father, a well to do and intelligent man. The child herself, without any solicition, complained that she saw double with each eye. The eyes presented a normal appearance in every respect and her vision was 6-6. I could find no evidence whatever, of cerebral trouble and I could give no satisfactory explanation of the phenomenon. Several of her teeth however, were badly decayed and I recommended their removal as a possible solution of the difficulty. I took no note of the color sense. A few days after the second visit, the last time I saw her, I received the following letter from the father: "March 3, 1890. Robert Tilley, M.D. Dear Sir: I am happy to say to you that my daughter's eyes seem to be now thoroughly well. The next day after I saw you, Mrs. M. took the child to the dentist and had the four bad teeth extracted. Since then she has had no trouble with her eyes. She used the prescription for a few days and seems to have entirely recovered." I did not quite believe this but supposed it was a polite way of saying that he had decided to change his oculist. As a preparation for this paper I went to the father's former office and learnt from his nephew that the child was the picture of health, and did not complain in any way about her eyes. That the father, after having for a year and a half, suffered from paralysis of the right side associated with, at the commencement, some difficulty in speech, died about the end of February of this year. I mention this fact as of some possible value in explanation of the cause of the phenomenon. He was about forty years old and paralysis of the right side with disturbance of speech in a man of that age has a probable significance.

(NOTE.—I have learned whilst here at Detroit, that the father contracted syphilis some fifteen years before I saw the child.)

Case 3.—Carrie H., a bright little girl of 8 years, complains of great discomfort in her eyes, disturbed with artificial light and of seeing two things with one eye. External appearance of the eyes normal, no sign of squint, or paralysis, or paresis, movement of eye good in every respect, V. 6-9, color vision normal, retinal vessels rather tortuous and fundus slightly mottled.

February 10, 1891. Says that yesterday while in school her vision left her for a while, says "it was the same as though her eyes were shut only it was light." When I saw her on the 19th, February, she claimed that the double vision had completely disappeared and her mother claimed that she was decidedly better in health. In a later report the mother informed me that the child did not complain any more of her eyes. This child is one of a family of two, her sister died of convulsions about a week after birth and she herself was cyanotic for some period after birth and is now afflicted with a general enlargement of the heart.

Case 4 was one of considerable interest, but one that I could not investigate to my satisfaction on account of peculiar circumstances. Hilda R., about 12 years, was the plaintiff for damages on account of alleged injuries in a railroad accident. She was completely hæmianæsthesic—left side—actual cautery pricking of pins elicited no response on the left side, bottle of officinal ammonia held to the left nostril provoked no expression of sensation, hearing appeared to be deficient, and sight a good deal below normal. The vision of both eyes was apparently deficient, and a deficiency of color sense. But what had not been observed was a well defined monocular diplopia in each eye. There was present during the examination the chief surgeon of the road as well as the family physician. I demonstrated the evidence of the monocular diplopia to surgeon, by a simple device. I put into the stereoscope, the card which I show you, the girl was of German parentage, and requested her to read everything she saw in the order in which it appeared. She read off every word twice. The fundus revealed a small amount of choroiditis, and the cervical glands were enlarged.

The nature of the accident was as follows: She was riding in a wagon, crossing a track, when a locomotive struck the wagon and projected the child a considerable distance. The left clavicle was broken and several small insignificant scalp wounds were made, but none of them in the posterior part of the head.

I reported that it was very improbable that the injuries were associated with the eye or ear symptoms, and in consequence of the choroiditis and enlarged cervical glands suggested to the lawyer to inquire into the family history of the child. The examination on the stand showed that the child's parents had had nine children, and only two were alive, the others having died in infancy; that the father's father had had eleven children, nine of whom died in infancy.

I have nothing more to add about this case. She was not my patient,I was only acting as an examiner and expert for the railroad. I have brought forward these items thinking they may contribute something to the elucidation of an obscure phenomenon. You will please observe that no claim was made on the part of the plaintiff of double vision, it did not seem to have occurred to any one interested in the prosecution, consequently that peculiar feature did not appear in the evidence. I should add, that during the trial she had an hysterical attack—screamed violently, and displayed well-marked athetosis of the fingers.

I will now try and show what of the various symptoms exhibited are common to all the cases. But before doing this I will remark that all cases that furnish a good ground for auto-suggestion should be thrown out as not belonging to the subject in hand; but on the other hand, auto-suggestion should not be entertained without a well defined reason. In our endeavors to avoid being deceived, especially relative to a statement for which we cannot assign a well formed theory, we are also in danger of deceiving ourselves. I will also call attention to what seems to be a mistake in the contribution of Dr. Thompson made to this Section last year. In referring to the case reported by Dr. Ord, said to be reported in St. Thomas Hospital Reports, 1879, it is stated relative to a boy of 13 years, "could find nothing abnormal in the eye or brain." I have not been able to consult St.Thomas Hospital Reports for that year, but Dr. Ord had a boy 13 years of age under his care in St. Thomas Hospital in 1879, and he is stated to have had an epileptic fit, but he himself states[1] that in dismissing the case he wrote as the nearest approach to a diagnosis cerebral tumor. Moreover, this same boy thirteen months later, Nov. 16, 1880, entered the "Leopold ward under Mr. McCormac, suffering from an abscess in the neck which was supposed to be connected with disease of some of the upper cervical vertebræ. He was then suffering from heart disease, and he died quite suddenly on the 20th of November, having giving no signs of cerebral affection, so that his death was supposed to be caused by sudden compression of the cord through giving way of the odontoid process." The result of the autopsy I gave in my communication of 1888. It was a large egg shaped blood clot 2½ inches long and one inch thick in the right hemisphere, encroaching on the lateral ventricle. I did not, however, add what is stated, that the hemisphere and the clot is preserved in the museum of St. Thomas' Hospital. I would like to call especial attention to the fact that notwithstanding this very gross lesion in the right hemisphere,the boy entered the surgical ward and no note was taken of any cerebral symptoms. So that it is not fair to suppose because gross cerebral symptoms are not observed, therefore, there are no lesions.

The chief symptoms,common to the three cases followed by an autopsy were convulsions,severe vomiting, great pain and double vision of one or both eyes. In some of those cases not terminating fatally there was present paresis or paralysis of some of the exterior muscles as well as the symptoms above indicated, in some milder cases there was practically little complained of except the diplopia together with some asthenopia.

In the three autopsies the chief lesion was found in the right cerebral hemisphere,whether the difficulty was chiefly referred to the right or the left eye. All of these lesions involved the posterior part of the hemisphere and one of them involved the cerebellum.

Whilst I do not think that it is proven that inherited syphilis has been an important factor in the most of these cases I regard it as very probable. You will remember that the case reported by Dr. Ord, although it left the hospital relieved of the severe symptoms which referred to the eye, reëntered with abscess in the neck associated with necrosed bone. In the case that I reported, abscesses appeared in various parts of the child's body. One child's father died a little while after I saw her from the effects of syphilis. The child that I examined for the railroad had choroiditis and enlarged cervical glands. Another child which I examined, Carrie H., a few days ago, although the diplopia had disappeared, had a well defined chain of enlarged cervical glands.

To explain the phenomenon I think the suggestion of Professor Foutan as practically satisfactory for the present,namely: That the impressions received by each eye are transmitted respectively to the right and left hemispheres and that in the normal condition ,these impressions are fused by communicating nerve fibres. When these communicating nerve fibres, however, are disturbed,double monocular vision should occur.

Asiatic Cholera.—Dr. R. W. Mitchell has had success with the following (Memphis *Med. Mo.*):

℞.	Acidi sulphurici dil,	ʒss.
	Morph. sulphat,	gr. ⅓.
	Spts. vini gallici,	ʒjss.
	Aquæ destillatæ,	℥iij.

M.—Sig. Inject under the skin of the arms, legs, and over the stomach every hour until symptoms of the disease are relieved.—*Medical Review.*

DOMESTIC CORRESPONDENCE.

History of Asiatic Cholera in New Orleans, La.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

The rapid progress of Asiatic cholera in Europe at this time, has justly alarmed the sanitary authorities of this great republic; but health authorities should not lose sight of the important fact that the *ordinary bowel affections at all times present with us inflict in the long run far greater mortality than Asiatic cholera.*

This proposition will be illustrated by the following

BRIEF HISTORY OF ASIATIC CHOLERA IN NEW ORLEANS.

It would be foreign to our purpose to enter fully into the history of this foreign pestilence which has at various times reached the shores of Louisiana from the shores of Europe across the waters of the Atlantic ocean and the Gulf of Mexico.

Asiatic cholera has played no insignificant part in the grand carnival of disease and death.

In 1832, Asiatic cholera in conjunction with yellow fever, swelled the mortality of New Orleans to 8,099 deaths, in a population of 55,084; and marked this year as the most terrible in the annals of this city, the death rate reaching the enormous proportion of 147.10 per 1,000 inhabitants.

In 1832, the inhabitants of New Orleans were more than decimated; more than one-seventh of their number were destroyed chiefly by Asiatic cholera, and yellow fever, as being in addition to the usual endemic and epidemic diseases.

The Charity Hospital affords the following statistics of Asiatic cholera:

1848,	cases, 662;	deaths, 396;	1849,	cases, 1,813;	deaths, 1,122;
1850,	" 724;	" 530;	1851,	" 382;	" 292;
1852,	" 485;	" 358;	1853,	" 194;	" 115;
1854,	" 478;	" 352;	1855,	" 351;	" 225;
1856,	" 32;	" 11;	1857,	" 1;	" 1;

Total, 1842–1860, (18 years).
Cases, 5,122; deaths, 3,402.
Percentage of deaths, 66.14.

During the 16 years following the civil war, New Orleans was comparatively exempt from Asiatic cholera, as shown by the statistics of the Charity Hospital Transactions:

1866,	cases, 300:	deaths, 237;	1867,	cases, 166;	deaths, 70;
1868,	" 15	" 9	1873,	" 34	" 27

Total cases and deaths, 16 years in the Charity Hospital (1864–1880) cases, 443; deaths, 343; per cent. of deaths, 77.4.

There were received into the Charity Hospital during 34 years (1846–1880) 5,565 cases of Asiatic cholera of which 3,745 terminated fatally, giving a rate of mortality of 67.3 per cent.

The first authentic records which we have of the appearance of Asiatic cholera in New Orleans, relate to the year 1832, when it occasioned 4,346 deaths out of a total of 8,099 deaths from all causes, yellow fever claiming only 400 deaths in this the most pestilential year in the annals of this city.

The disease claimed 1,000 victims out of a total of 34,976 deaths in 1833. In 1832, 78.78 per 1,000 of the inhabitants were destroyed by Asiatic cholera.

Cholera appeared again in 1848, and destroyed 1,646 inhabitants, and continued its ravages for some years, the deaths being:

Year.	No. Deaths.	Year.	No. Deaths.
1849	3,176	1858	28
1850	1,148	1859	27
1851	430	1860	30
1852	1,329	1861	17
1853	585	1863	4
1855	883	1864	5
1856	46	1865	9
1857	24		

Total deaths from Asiatic cholera in New Orleans, during a period of 19 years (1844–1865) 9,678.

Cholera appeared again in 1866, and continued its ravages for three years. The deaths were as follows:

Year.	No. Deaths.	Year.	No. Deaths.
1866	1,294	1871	6
1867	581	1873	142
1868	129	1874	6
1869	4	1875	4
1870	3		

Total deaths during 15 years (1866–1880) 2,169.

It is evident from the preceding statistics, that during a period of 34 years (1846–1880) Asiatic cholera destroyed 11,847 of the citizens of New Orleans, and if we add to this the number of deaths occasioned by the disease in 1832 and 1833, we have a grand total of 17,187 deaths.

It is probable that the mortality occasioned by Asiatic cholera was far more in excess of these figures, for we find upon careful examination of the mortuary records of New Orleans, that during a period of 34 years (that is 1846 to 1880) the deaths from bowel affections were as follows:

Cholera morbus	889
Cholera infantum	2,408
Teething	3,430
Gastritis	743
Enteritis	6,916
Dysentery	7,097
Diarrhœa	8,289
Total	29,772

During the same period of 34 years, yellow fever occasioned 28,739 deaths.

It is evident, therefore, that the so-called ordinary bowel affections, diarrhœa, dysentery, cholera morbus, enteritis, gastritis, and teething (cholera infantum), actually caused a larger number of deaths in New Orleans than yellow fever. And if we add the 11,847 deaths caused by Asiatic cholera, we have a grand total of 41,618 deaths from these diseases in which derangements of the gastric intestinal mucous membrane forms the most prominent symptoms. The continuous and fearful mortality of this class of diseases must be diminished by improved and domestic sanitation.

The great essentials of sanitary reform for the diminution of the ravages and fatality of the cases of bowel affections in New Orleans must be based upon:

1. Thorough drainage of the entire parish of Orleans, and especially that portion occupied by the city of New Orleans.
2. The prompt removal of all fecal matter out of the limits of the city.
3. The daily removal of garbage.
4. Systematic and thorough cleansing and disinfection of private premises, public buildings, factories, markets, streets and gutters.
5. The filling up with sand and gravel of all low lots.
6. Free supply of pure filtered river water to all classes at the lowest possible cost.
7. The honest and efficient inspection of markets, milk, meat, fish, fruit and food supplies.

Respectfully,

JOSEPH JONES, M.D., LL.D.

156 Washington ave., New Orleans, La., August 30, 1892.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.—By order of the Council, the annual meeting of the Association has been postponed from the 8th, 9th and 10th, until the 15th, 16th and 17th of November. It was thought wise to change the time of meeting from the fact that the 8th of November is the date of the Presidential election.

Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 10, 1892.

THE CHOLERA PSYCHOLOGICALLY.

The arrival of cholera opens up a new phase of preventive medicine that so far has not attracted much attention. The old proverb that fear kills more persons than disease, is likely to be fearfully illustrated in this country. Already the press has begun with the most minute and exhaustive descriptions of this disease, and its varied symptoms. The natural dread and panic which exists following every sudden mysterious epidemic is intensified to an alarming degree. Each reader is unfitted both physically and psychically to resist the germ poisons. The vital centers are depressed and he is placed in the most favorable condition to be attacked, and to succumb at once. The cleaning up of streets and sewers, and placing the towns and cities in the best hygienic conditions is only a part of the real preventive remedies. The army of neurotics, and the nerve and brain exhausted men and women of every town and city, need protection from this mental source of danger. The more minutely and graphically cholera is described, the greater the number of victims from these classes. A psychical contagion will break up the conservative power of the nerve centers, and precipitate profound depressions that will take on all the characteristic symptoms, even to death. Every where the profession should protest against this indiscriminate publication of details of this epidemic. People should be advised not to read long accounts of the progress of this disease. Boards of health, and sanitary authorities, should point out the danger from this source, and urge the press to conform to the teachings of science, and aid in the efforts to limit this scourge. If medical men would keep a record of panic struck mental cases, which are sure to occur in every town, very interesting data would be gathered. While these facts are not new, and are more or less familiar to every medical man, they are overlooked in the excitement of the time and occasion. They are of much greater interest in this country than elsewhere, because of the freedom of the press, the greater skill and facilities of writing up these events, and the larger number of daily readers who depend on the papers for their usual excitement. If the New York, or other large dailies, should describe these cholera cases, as dying with wild shaking delirium, a large proportion would have these identical symptoms. This takes place in other cases and has been pointed out many times before.

To avoid a panic in times of excitement is practically to suppress all details in the daily press, especially in matters of disease. The profession ought to join everywhere in teaching the press the danger of publishing details of epidemics. Already two cases are reported of deaths with all the symptoms of chlorina where the victims read minutely all the press accounts of cholera. While cholera may not be very serious or wide spread in this country, it is evident that its control is largely in the hands of the profession, and that prevention is the highest achievement of science. The public will of course demand the latest news of its progress, but only the morbid neurotics will call for the details, and the symptoms of its appearance; but the press owes a duty to the public to suppress these, as a sanitary measure While it is not likely this will be done at present, we urge our readers to observe and gather up all records of cases, that can be traced to this source. Preventive medicine will demand in the near future the removal or correction, of all psychical as well as physical causes. Science will teach that epidemics have other than germ poisons to perpetuate and extend their destructive power.

The press advice to keep cool and avoid panic, must be coupled with the most general facts of the progress of the evil. Otherwise they furnish the very material and germ forces for the most aggravated panic, because it is applied to each one personally, and vast numbers of persons can not avoid the inevitable contagion of applying to themselves, the conditions described. The cholera will be fatal in many cases, but mental contagion growing out of the unstrained publication of all symptoms, will have far more victims.

The germ soil is here, and all the conditions are favorable, let the reporter write up in the usual sensational way the coming disease, and it may be here at once in all its virulence.

THE MEDICAL ASPECTS OF CRIME PREVENTION.

A governmental report on the Fourth International Prison Congress held at St. Petersburg has appeared under the editorship of HON. C. D. RANDALL of Michigan. We desire to commend the document to all medical men who indulge a taste for the study of correctional reform. An address contained in this volume, by SENATOR CANONICO, of Rome, may be quoted briefly since it places a most remarkable value on the influence that may be exerted by physicians for the reformation of vicious persons. He says: "The physician is, above all, the director of the prison, and he ought to be. Entering with a loving and devoted spirit the place of each convict, seeking to possess his confidence, laboring with each according to his disposition; better than any one else he can contribute to the awakening of the conscience. The pivot of prison reform is a good personal direction. But the most essential and difficult matter will be to make the diseased person—that is to say, the prisoner—consent to take the remedy. If he will not take it when properly prescribed the fault will not be in the remedy, nor in the physician, but in the patient himself. We build prisons, but what is more difficult is to introduce into them the spirit of penitence." It is without doubt true that of all the persons who come into contact with prisoners the physician is the one who can with the least difficulty win their attention, but to how many of our jail physicians has the thought occurred that they have before them the same line of possible benefactions that gave to JOHN HOWARD an undying name?

HEAD TETANUS OF ROSE.

The infrequency with which certain diseases are observed in the human subject is occasionally a consideration worthy of discussion. At first it would appear as though there must necessarily be some peculiarity in the individual or upon the part of the etiological factor not present in other cases. Those diseases which are clearly of bacterial origin are of greatest interest in this particular direction. A biological study of bacteria, including their manner of propagation, their range of conditions for development, and their parasitic propensities may possibly give a key to the situation. Such facultative parasites as the tetanus bacillus or that of malignant œdema may never produce disease until accidentally transferred to some host where they are capable of growing and producing characteristic changes. These examples of accidental infection are often of so rare occurrence that an instance is not seen among thousands of cases of disease. Their rarity and the interesting facts that may be adduced from them, require that each instance should have a complete history and an exhaustive clinical examination. What geologist would allow a rare form of fossil bivalve to go unpublished, or would an embryologist permit an unusual case of fission to be forgotten? Such neglect could never occur to the true scientist. Yet it is true that in general practice, the value to be derived from such cases is lost owing to inadvertence or failure in a timely consideration. The neglect to publish or to notice previous cases, is also a fault of frequent occurrence. As an example, NICHOLAIR (*Virch. Arch.*, Band 128, Heft I, 1892) deplores the fact that a case of so-called ROSE's head tetanus which was observed and investigated by him remained without notice by contemporaries. As only some forty-two or three cases in all have thus far been recognized, it may be appropriate to recall the subject at this point.

In 1870 ROSE reported a peculiar clinical form of tetanus that occurred after injuries to the face and neck. *It was characterized by facial paralysis* upon the side of the injury and subsequent tonic contractures of the musculature of the neck and larynx. BRUNNER inoculated guinea-pigs with the tetanus cultures upon one side of the head and observed contractures throughout the distribution of the facial nerve, and later trismus and general contractures. It would appear, because of the failure to produce facial paralysis experimentally in animals, that there were other factors, beyond the tetanus infection present in man. In France several cases of head tetanus were examined bacteriologically, and although many microörganisms were demonstrated, yet the *tetanus bacillus was not isolated.* ROUX and SPANJE reported their investigations negatively. The reason probably being in a failure of their methods. FLUGGE and REMBOLD produced tetanus by introducing a *splinter from a case of head tetanus into mice,* but did not demonstrate tetanus bacilli. The case of NICHOLAIR was presented by himself and BRENNICKE in 1890. Here also inoculation experiments were negative for the brain, cord or cranial nerves, but when mice were inoculated with material taken from the neighborhood of the wound they died from tetanus in twenty-four hours. From these, pure cultures were obtained. This demonstration places bacillus without doubt as the etiology of head tetanus. The pathological significance of the facial paralysis has given rise to considerable dispute. BERNHARDT and others have accepted the possibility of a toxalbumen. And this can be none other than a ptomain produced by the tetanus bacillus. Just why the facial nerve should suffer has been explained by ROCKLIFFE and ROBERTS as due to a greater susceptibility of this nerve, while BRUNNER thinks that its more superficial position may be taken as a satisfactory cause.

Contributions to recent medical science are obtained only through persistent and painstaking effort. The gross principles have been promulgated, but it still remains to investigate and specify the details. Such experimentation can only come from the best equipped hospitals and laboratories. That America is not on a level with modern experimental science may be traced directly to this absence of equipment. Just at this time the laboratory element in medical education is manifesting itself in this country and from it and its patient workers alone can we expect to assume the foremost position in medicine.

EDITORIAL NOTES.

The Insanity of Egotism.—An article has appeared in the *North American Review*, entitled "A Modern Form of Insanity," by Dr. H. S. Williams, which throws some interesting lights upon those indifferently understood persons "the cranks." Dr. Williams holds that the great majority of these unfortunates are diseased mentally. The disease has been termed "paranoia," and more than any other insanity is the result of an inherited mental instability. The progenitors may not have been insane, but they may have been nervously unstable from drunkenness or from some wasting disease. The offspring may be merely nervous; he may have epilepsy or chorea; he may be insane. At the best, he may usually, if properly educated, learn to understand himself and to live a sane and useful life. We have here to do, however, only with the cases in which a wrong environing influence aids in the development of a particular form of insanity. It is possible to outline pretty definitely the mental attributes. One may even point out in the child what might be termed the paranoiac temperament. Its characteristics are morbid sensitiveness and great egotism. Unfortunately, the parents of such a child usually take pride in the egoism that leads to eccentric acts, while the extreme precocity of many of these subjects causes their egotism to be fostered by ill-adjudged praise. Usually the child of paranoiac temperament is the genius of his family and the show pupil at school. Pampered and praised, even though the entire household becomes subordinated to his sovereign will, he is not satisfied, believing that he does not receive his dues. With that idea, the germs of paranoia are planted in his mind. Whether or not these germs will develop into the pathological condition that we are discussing, will depend largely upon the influences that are brought to bear upon them during adolescence and early manhood. Perhaps the most unfavorable environment is one in which the mind is developed at the expense of the body. And of course, the brilliant child is the one whose mental training will be forced. The other children of the family may stay at home, but this one must be sent to college and fitted for one of the learned professions. Usually he seems to justify this discrimination. Often he is an "honor" man at college, and he starts out into the world with every seeming prospect of an eminently prosperous career. But all this time he has become more and more eccentric. He has associated little with his fellows. Often he has shown himself possessed of extraordinary energy and capacity for application. A peculiarity often noted is a tendency to make elaborate written records of trivial subjects. Occasionally the young person of paranoiac temperament breaks down under the unbalancing influences of overstudy while still at school. But usually the critical stress comes after he has gone out into the world. He is usually not yet insane. He may never become so. If his business or professional ventures succeed, he may become distinguished, and contact with the world may gradually correct the morbid tendencies. But if adverse circumstances arise and refuse to be put down, especially if the individual's vanity is wounded by failure to rise to the heights pictured by ambition, morbid brooding may develop out of vanity, selfishness and suspicion, the delusion of persecution. But it must not be supposed that the mature condition is merely egotism and egoism run riot. That it has come to be something more than this is proved by the appearance, sooner or later, of hallucinations of one or more of the senses. These do not necessarily coincide at first with delusions. The incipient paranoiac may hear voices about him and for a time be able to convince himself of their unreality. But, sooner or later, these sounds become so tangible that they have the full force and import of actual voices. At first he hears them only when people are actually speaking, his mind merely misinterpreting what it hears. This perversion is technically termed an illusion. But at last he hears words and sentences when no real sound comes to his ears; these are true hallucinations. Perversions of other senses usually precede or follow this one. Illusions of touch and smell are common. The former lead to a belief in invisible spirits that touch the body; and the latter convince the patient that attempts are being made to poison him with noxious gases. When to this cluster of perverted sensations hallucinations of sight are added, the galaxy is complete, and the victim moves and has his being in an ideal world peopled with odors, tastes, sounds and sights that are shut out from the common herd. The patient lives a dual existence. For a time he is able to treat the actual world in the old familiar way—that is, sanely; meanwhile keeping the new and strange world hidden. But gradually he comes to confound the two existences. He comes to believe that hosts of people are leagued against him, and all sane interests give way to a desire to thwart those imagined foes. At this stage of his morbid career the patient becomes very dangerous, though he may still seem to be the most peaceable of men. Murders are often committed by patients in this condition. But many more intended murders that are carefully planned are never executed because of the irresolution of the would-be murderer.

Inguinal Bubo Resulting in Death by Hæmorrhage.—The *Boston Medical and Surgical Journal*, July 28, contains a report, by Dr. John Homans, of a case of bubo terminating in fatal hæmorrhage. It is rare that a sloughing inguinal abscess progresses to the extent of destroying the life of the patient in this manner, but neglect of treatment may as in this case readily lead up to such a fatality. Dr. Homan's patient, a male, observed in November, 1891, an inguinal swelling, which he declined to have opened. On December 8, the abscess "pointed and broke" the slough separating six weeks later. There was an oozing of blood March 18, which became a hæmorrhage on the 21st. The patient had continued at his occupation until this latter date, when he was admitted to the hospital. The femoral artery was deligated, on both sides of the slough, in its wall. Transfusion and stimulation were employed without avail, the patient succumbing after two days.

Coffin-Birth.—Under this term, Bleisch has reported, in the *Viertschrift fur gericht Medicin*, a case of probable post-mortem fœtal expulsion. A woman, attended by two midwives, was taken with labor pains at the end of a normal pregnancy, and after two hours of fruitless labor died. A medical examination, two hours after the death of the patient, disclosed the non-delivery of the fœtus. About three hours later the body was put in a coffin. After an interval of three days the coffin was opened and the body examined. The uterus was found inverted and extruded. A dead child, still attached to the placenta, lay between the thighs of the dead mother. It had probably been expelled subsequent to the mother's preparation for burial. By some, the expulsion post-mortem is held to be due to uterine contractions during the *rigor mortis*, the fœtus having been already advanced toward delivery by preceding vital effort. By others the post-mortem birth is explained as a result of the formation of the gases of decomposition. Possibly the interaction of these two agencies may be necessary to the production of "coffin birth."

An Army Medical Board will be in session in New York City, N. Y., during October, 1892, for the examination of candidates for appointment to the Medical Corps of the United States Army, to fill existing vacancies.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before October 1, 1892, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character, and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a regular Medical College, as evidence of which, his diploma must be submitted to the Board. Further information regarding the examinations may be obtained by addressing the Surgeon General U. S. Army, Washington, D.C.

C. Sutherland, *Surgeon General U.S. Army.*

SELECTIONS.

The Mechanism of Concussion of the Brain.—In *Brain*, part i of volume viii, there is a paper by Dr. Alexander Miles supporting and confirming the conclusion published by Duret, that the group of phenomena commonly spoken of as "concussion of the brain" is the result of a temporary anæmia of that organ. This anæmia is the reflex result of stimulation of the restiform bodies, and perhaps of other important centers in the region of the bulb, produced by the wave of cerebro-spinal fluid which rushes through the aqueduct of Sylvius and the foramen of Magendie from the subarachnoid space of the brain to that of the spinal cord when a severe blow is dealt over the skull. In accordance with the laws of hydrostatics this cerebro-spinal wave will disturb the equilibrium of the ultimate nerve cells throughout the central nervous system. The hæmorrhages found throughout the brain substance and on its surface are to be ascribed to the recession of the cerebro-spinal fluid, which naturally supports the blood-vessels of the cerebrum. These petechial hæmorrhages are not the proximate cause of the symptoms of concussion, but are rather to be looked upon as an index of the force that produced the injury.

A Bacteriological Study of Drinking-water.—Dr. Victor C. Vaughan has published (*Am. Jour. of the Med. Sci.*, August, 1892) the results of his work in the bacteriological study of drinking-water since 1888. He describes the methods by which he obtains his samples, makes cultivations and inoculates animals. He concludes that many of the germs found in drinking-water will not grow at the temperature of the human body, and are therefore incapable of producing disease. Of the germs which grow at 38° C., or at higher temperatures, some are fatal to animals (toxicogenic) when injected subcutaneously, while others are not (non-toxicogenic). The non-toxicogenic germs do not multiply when injected under the skin or into the abdomen of animals; but this is not sufficient evidence that they would not multiply in the human body, so water containing them has been regarded as suspicious. Some of the toxicogenic germs produce the same symptoms and post-mortem appearances in animals as Eberth's bacillus; the properties of the former are fully equal to those of the latter, and they not only live but multiply in the animal body; water containing them was always condemned. It was found that more than one germ obtained from drinking-water grew with an invisible growth on potatoes, and that several grew on the media proposed by Parietti, Uffelman and others, as a means of recognition of Eberth's bacillus.

Syphilis in Nineveh and Babylon.—In *Le Progrés médical* for July 16, there is a *résumé* of a brochure by F. Buret on an interesting legend that a scribe of Sardanapalus had engraved in cuneiform characters on a brick that is now in the British museum. Istar, the goddess of illicit love, fertility, and war, the mother of the gods and of men, seduced by the lustiness of Nimrod, had solicited that hero to take her as his wife. He ungallantly refused and continued to hunt in the woods with his comrade, Eabani, a male himself, for he also could uninterruptedly employ six days and seven nights in amusing himself with the *la lú* of his sweetheart. Outraged and indignant, Istar demanded that her father, Anu, should send the sacred bull against this rebel. But Eabani had no fear of ferocious beasts, and, seizing the bull's penis, threw it at the goddess's face. Istar's fury made all the planetary system tremble, and after twelve days of struggling, Eabani was struck by death. Nimrod was afflicted with a loathsome leprosy that made his hair fall out, and his body was covered with scaly patches, and there were pustules on the phallus that was adored at Babylon. He descended into hell and was purified by the fountain of life. The author has given in a former work what he considers proof of the existence of syphilis among the ancients; and he finds in this legend of the punishment of Nimrod confirmation of all that he has written on the subject.

The Action of Phenocol Hydrochlorate.—Dr. Rudolph Bum obtained the following results from the use of this drug in wafers in the dose of 0.5–0.7–1.10 gram, and in the daily amount of 5.0 grams. Even in small doses it is a powerful, almost sure antipyretic in phthisis. In case of great weakness and in the last stages of the disease the drug should not be used. It has a slighter and much less constant action in erysipelas even when given in large doses. It has only a slight antipyretic action in rheumatism, and does not affect the disease. In migraine it acts well in doses of 0.5 gram, but has no effect in myelitis or sciatica. Unpleasant effects on the digestive tract occurred in only a few cases.—*Boston Med. and Surg. Journal.*

The Digestibility of Various Kinds of Cheese has been recently tested by a German chemist, who placed the samples in fresh gastric juice. Cheshire and Roquefort cheese took four hours to digest; Gorgonzola and Neufchatel, eight hours; and Brie and Swiss cheese, ten hours.—*Med. Record.*

NECROLOGY.

The Late Dr. Catlin.

At a meeting of the medical fraternity of Rockford, Aug. 30, 1892, the following resolutions were unanimously adopted to express the feelings of the profession concerning the death of Dr. A. M. Catlin:

Whereas, Our honored and venerable associate and friend Dr. A. M. Catlin, has entered upon a wider opportunity beyond, after having advanced to the age of 91 years, and practiced more than half a century in this community, and consequently had witnessed and taken part in the wonderful development of medical and other sciences for nearly a century; and who by his upright and consistent christian character, by his faithful and ever constant devotion to his profession, by his courteous relation to his professional brothers, to his friends and the community at large, has inspired us who remain behind to express our deep appreciation of the life that is spent; therefore

Resolved, That in the death of our brother the profession of this city has lost an esteemed and cherished member, a man of multiple virtues and no vices, and the community a man of ripe years and wisdom, who, having lived in this city from its infancy, did much to make its institutions and industries what they are.

That to his family we tender our sincere sympathy in the withdrawal from their midst of the reverent, kindly, charitable spirit that has blessed them for so many years, and express our earnest belief that these associations, beautiful here, will be renewed and perfected hereafter; and

That a copy of these resolutions be conveyed to his family and furnished for publication in THE JOURNAL of the American Medical Association.

DR. THOMAS FANNING WOOD, editor of the *North Carolina Medical Journal*, died at Wilmington, on the 22nd ult., from cardiac disease. He was born in 1841, at Nantucket, Mass. He pursued his medical studies at the Virginia Medical College and the Maryland University, taking an honorary degree from the latter institution in 1868. He settled in Wilmington and joining the New Hanover county association became its president in 1875. He was the Secretary of the State Medical Society for many years beginning in 1867. From 1863 to 1865 he was an assistant surgeon in the Confederate service, and in 1866 in charge of the small pox pavilion of Wilmington. He was a member of the State Board of Medical Examiners and Secretary of the State Board of Health. Under his direction was published the interesting little monthly Bulletin of sanitary reports, from the various local boards and committees, throughout the State. He was one of the early members of the American Public Health Association. He was a member of the American Medical Association at various times since 1878. He was connected with the *North Carolina Medical Journal* from its inception in 1878, and for a number of years was its sole editor. He had been a sufferer from aneurysm and believed himself to have been greatly benefited by rest-treatment, during a period of two years or more, and was enabled to resume a share of his public and professional duties, yet his final illness, as reported by the news-telegrams, namely cardiac disease, may have been a legacy of his former disability. Although cut down in the prime of his mental vigor he has left a record of thirty very diligent and useful years in literary and sanitary fields of labor.

DR. WILLIAM H. HENDERSON, professor of clinical medicine in the Royal College of Physicians and Surgeons, Kingston, Canada, died on the 14th ultimo, in the 37th year of his age. The final illness was due to pulmonary œdema following Bright's disease. He was a member of the college of Physicians and Surgeons, Ontario, since 1880, and a member of numerous societies.

BOOK REVIEWS.

TRANSACTIONS OF THE AMERICAN CLIMATOLOGICAL ASSOCIATION. Vol. 8. Philadelphia: W. B. Saunders, 1892. 8vo. pp. 276. Price $1.50 net.

The contents of this volume are of much wider scope than the title indicates.

The subject of influenza occupies much space, and excellent reports are given of the epidemic as it appeared in different cities, including Philadelphia by Curtin and Watson, Chicago by Fletcher Ingals, St. Louis by J. C. Mulhall and Savannah by R. J. Nunn. The discussion upon these reports was indulged in very generally by the members of the Society and took a wide range.

Pulmonary Tuberculosis is given much consideration, and papers relating to some phase or other of this important subject were read by Drs. E. L. Shurley, Edward O. Otis, Alfred L. Loomis, S. A. Fisk, H. F. Williams, T. Hilgard Tyndale, Frank Fremont-Smith, Wm. C. Glasgow and H. B. Moore.

Lymphatism is considered in a short but interesting paper by F. H. Bosworth. Dr. J. H. Musser has a suggestive paper on whooping cough. Among the other papers should be mentioned: "Notes on General *versus* Local Treatment of Catarrhal Inflammations of the Upper Air-tract," by Beverly Robinson, "Medical Treatment of Pleurisy" by G. M. Garland, "The Climate of the Greater Piedmont and Mountainous Regions of the Southern United States" by W. C. Van Bibber, "Nervo-vascular Disturbances in Unacclimated Persons in Colorado," by J. T. Eskridge, "The Surgical Treatment of Acute and Chronic Empyema" by Maurice H. Richardson and "An Experience with Diphtheria at a High Altitude" by Walter A. Jayne. The discussions are very interesting and add much to the value of the book.

THE PATHOLOGY AND PREVENTION OF INFLUENZA, by JULIUS ALTHAUS, M.D. New York: G. P. Putnam's Sons. 1892.

This little monograph of sixty-four pages is an amplification of a paper read before the Medical Society of London, and published in the *Lancet* for November 14, and 21, 1892. The author's purpose is to show "that the symptoms of influenza are owing to the action in the system of a special poison secreted by a pathogenous bacillus; that this poison has a special affinity to a definite centre of the nervous system, which is irritated and depressed by it, that an antidote which is able to neutralize the effects of the poison is formed in the blood of the patient, and tends to effect a spontaneous cure of the disease; and that the nearest approach to this antidote which we at present possess appears to be animal vaccine lymph."

PRESCRIBING AND TREATMENT IN THE DISEASES OF INFANTS AND CHILDREN. By PHILIP E. MUSKETT, late Surgeon to the Sydney Hospital, etc. Philadelphia: P. Blakiston, Son & Co. 1891.

This little book is divided into three parts, the first of which relates to dosage and therapeutics, the second to the treatment of diseases, and the third to recipes. The first part is of considerable service in suggesting the dosage of various remedies in various conditions. The second part arranged alphabetically under the names of diseases, is quite routine and not very inspiring. The subject matter is decidedly too old for a modern book on pediatrics.

ATLAS OF CLINICAL MEDICINE. By BYRON BRAMWELL, M.D., Assistant Physician to the Edinburgh Royal Infirmary, etc.

Volume i, Part 4, of this excellent work has just been issued by the University Press, Messrs. T. and A. Constable. The contents of the number are: Small-Pox; the Clinical Investigation of Cases of Small-Pox; A Remarkable Case of Globulinuria; Dr. Noël Paton's Observations on Globulinuria; Three Cases of Friedreich's Ataxia; Case of Chronic Insanity; Case of Hilarious Mania. The plates are: four of small-pox, two of melancholia, one of melancholia with strong suicidal tendency, two of mania. The high character of the work has been well maintained.

LECTURES ON PATHOLOGY DELIVERED AT THE LONDON HOSPITAL. By the late HENRY GAWEN SUTTON, M.B., F.R.C.P. Edited by MAURICE EDEN PAUL, M.D., and revised by SAMUEL WILKS, M.D., LL.D., F.R.S. Philadelphia: P. Blakiston, Son & Co. 1891.

Every page shows the author's individuality, and magnificent common sense. While nominally a work on pathology, the author devotes much time to etiology, symptomatology, and treatment. In style the didactic form prevails, and makes the book exceeding readable. The ground covered is extensive. no less than 53 separate lectures being included, but it is in no sense a systematic treatise. It is never common place and should be read by all thinking physicians.

MISCELLANY.

The Medical Society of the Missouri Valley.—The annual meeting will be held at Council Bluffs, Iowa, September 15, 1892.

9:00 a.m. Registration and payment of dues. Organization. Report: Committee on credentials. Reading minutes. Miscellaneous business. Report: Committee of arrangements.

Papers: 1. Pelvic inflammations following parturition, Dr. J. G. Biller, Cherokee, Iowa. 2. Was it Auto Suggestion? Dr. S. Grover Burnett, Kansas, City, Mo. 3. The Region of the Macula Lutea in Ophthalmoscopy, Dr. M. F. Weymann, St. Joe, Mo. 4. Deformities of the Lower Limbs, Dr. J. W. Cokenower, Des Moines, Iowa. 5. Fibroid of the Uterus, report of Case, Dr. Frederic Bacon, Omaha, Neb. 6. Thrombolic Abscess, report of two Cases, Dr. Ira E. Atkinson, Fremont, Neb. 7. Malthusianism, Dr. J. M. Richmond, St. Joseph, Mo. 8. Trendelenburg's Position in Pelvic Surgery, Dr. J. E. Summers, Jr., Omaha, Neb. 9. Empyema, Dr. Donald Macrae, Council Bluffs, Iowa. 10. A Study of Seven Fatal Laparotomies, Dr. Emory Lanphear, Kansas City, Mo. 11. Cystitis in the Female, Dr. B. F. Crummer, Omaha, Neb. 12. Appendicitis, Medical and Surgical Management, Dr. A. F. Jonas, Omaha, Neb. 13. Retained Placenta, Dr. H. B. Lowry, Lincoln, Neb. 14. Warm Antiseptic Baths in Inflammations, Dr. Wm. Jepson, Sioux City. Iowa. 15. Chloroform Narcosis, Dr. H. Gifford, Omaha, Neb.

The Tri-State Medical Society of Alabama, Georgia and Tennessee.—List of papers for the fourth annual meeting, which will be held in Chattanooga, October 25, 26 and 27, 1892:

"Eye Symptoms in General Disease," J. L. Minor, Memphis, Tenn.

"Talipes Equino-Varus" (with presentation of patients), C. W. Barrier, Rome, Ga.

"Sequences of Otitis Media Purulenta," T. Hilliard Wood, Nashville, Tenn.

"Report of 1,050 Strabismus (Cross Eye) Operations, with some Observations on the Same," A. W. Calhoun, Atlanta, Ga.

"Special *vs.* General Practice in Medicine," W. J. Killen, Birmingham, Ala.

"Synovitis," J. B. Cowan, Tullahoma, Tenn.

"The Present Status of Medical Education in the South," Luther B. Granby, Atlanta, Ga.

"Pharmaceutical Preparations of the Present Day," Jno. C. Le Grand, Anniston, Ala.

"A Clinical Study of the Relation between Scarlet Fever and Diphtheria," W. D. Hoyt, Rome, Ga.

"The Treatment of Inguinal Hernia," J. W. Handly, Nashville, Tenn.

"Fistula in Ano," Andrew Boyd, Scottsboro, Ala.

"Stricture of the Male Urethra; its Diagnosis and Treatment," W. L. Gahagan, Chattanooga.

"Phymosis," Erasmus T. Camp, Gadsden, Ala.

"The Rational Treatment of Enlarged Prostate in Old Persons," Geo. W. Broome, St. Louis, Mo.

"Advanced Theories in Psychical Science," Jno. E. Purdon, Cullman, Ala.

"Drunkenness and Its Gold Cure?" John P. Stewart, Attala, Ala.

"Surgery—Things to Do and Things not to Do," Willis F. Westmoreland, Atlanta, Ga.

"A Few Selected Cases in Laparotomy," W. H. Wathen, Louisville, Ky.

"Extra-Uterine Pregnancy," Richard Douglass, Nashville, Tenn.

"The After Treatment of Abdominal Operations," W. E. B. Davis, Birmingham, Ala.

"Hepatic Abscess," E. B. Ward, Selma, Ala.

"Report of Treatment of Sterility," J. M. Head, Zebulon, Ga.

Titles not announced: Jno. L. Howell, Knoxville, Tenn.; J. M. Masters, Knoxville, Tenn.; C. S. Briggs, Nashville, Tenn.; I. N. Love, St. Louis, Mo.

The Committee have secured a one and one-third rate from the railroads on the certificate plan. The meeting promises to be one of unusual interest.

The American Electro-Therapeutic Association.—A very full program is announced for the coming meeting of the American Electro-Therapeutic Association which is to be held in New York, at the Academy of Medicine, 17 West 43d street, October 4, 5 and 6. There will be two interesting discussions one upon "The Relative Fœticidal value of the different Currents and their Application to Ectopic Gestation," to be discussed by many prominent Gynecologists and Electricians, and another upon "Cataphoresis and its Practical Application as a Therapeutic Measure."

Papers are announced by Drs. Geo. J. Engleman, Wellington Adams, and Geo. F. Hulbert of St. Louis, Wm. F. Hutchinson, of Providence, R. I., Franklin H. Martin, of Chicago, Ill., A Lapthorn Smith of Montreal, Canada, R. J. Nunn of Savannah Ga. Thomas W. Poole, of Lindsay, Ontario, C. Eugene Riggs, of St. Paul, W. J. Herdman, of Ann Arbor, Mich., D. S. Campbell, of Detroit, Mich., G. Betton Massey, of Philadelphia, Henry D. Fry, of Washington, D. C., H. E. Hayd, of Buffalo, N. Y., J. H. Kellogg, of Battle Creek, Mich., C. G. Cannaday, of Roanoke, Va., Ernest Wende, of Buffalo, N. Y., and Wm. J. Morton, Augustin H. Goelet, A. D. Rockwell, Landon Carter Gray, Robert Newman, Ephraim Cutter, Frederick Peterson, G. M. Hammond, F. Van Raitz, of N. Y., and many others. Dr. J. Mount Bleyer, will give an instructive lecture with demonstrations entitled, "The Phonograph and Microphonograph, the Principles underlying them and their Uses in the Sciences."

In connection with the meeting, there will be an exhibition of modern medical electrical apparatus, all the prominent manufacturers being represented.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from August 20, 1892, to August 26, 1892.

Capt. Louis M. Maus, Asst. Surgeon U. S. A., so much of Par. 9, S. O. 194, A. G. O., August 18, 1892, as relates to change of station, is suspended until further orders. By direction of the Acting Secretary of War.

Major Paul R. Brown, Surgeon U. S. A. (Ft. Supply, I. T.), is granted leave of absence for one month, to take effect on or about September 1, 1892.

Major Joseph K. Corson, Surgeon U. S. A., leave of absence granted is extended one month.

Lieut.-Col. Charles R. Greenleaf, Deputy Surgeon-General, now at Montpelier, Vt., will proceed to Plattsburg Bks., N. Y., on business connected with the Medical Department, and on completion thereof will return to Montpelier.

First Lieut. Paul Shillock, Asst. Surgeon U. S. A., now on temporary duty at San Carlos, Ariz. Ter., is relieved from duty at Ft. Grant, A. T., and assigned to permanent duty at San Carlos, A. T., relieving First Lieut. Nathan S. Jarvis, Asst. Surgeon. Lieut. Jarvis, on being relieved by Lieut. Shillock, is ordered to Ft. Apache, A. T., for duty, relieving Capt. Louis M. Maus, Asst. Surgeon. Capt. Maus, on being relieved by Lieut. Jarvis, is ordered to Whipple Bks., Ariz. Ter., for duty.

Capt. Richard W. Johnson, Asst. Surgeon U. S. A., is relieved from duty at Ft. Bayard. N. M., and ordered to Ft. Bowie, A. T., for duty at that station, relieving First Lieut. Philip G. Wales, Asst. Surgeon. Lieut. Wales, on being relieved by Capt. Johnson, is ordered to Ft. Bayard, N. M., for duty at that station.

Capt. Walter Reed, Asst. Surgeon U. S. A., upon the arrival of First Lieut. Charles F. Mason, Asst. Surgeon, at Ft. Snelling, Minn., will be relieved from duty at that station, and will report in person to the commanding General, Dept. of Dakota, for duty as attending surgeon and examiner of recruits at the headquarters of that Department.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending September 3, 1892.

P. A. Surgeon E. H. Marsteller, detached from practice ship "Constellation," and to the Naval Academy.

Asst. Surgeon James Stoughton, detached from practice ship "Constellation," and to wait orders.

P. A. Surgeon W. F. Arnold, ordered to Naval Station, Port Royal, S. C.

P. A. Surgeon S. H. Griffith, detached from the U. S. S. "Jamestown," and to the U. S. S. "Constellation."

ORIGINAL ARTICLES.

THE CONSERVATIVE TREATMENT OF LACHRYMAL OBSTRUCTION.

Read before the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, June, 1892.

BY S. D. RISLEY, M.D.,

Attending Surgeon at the Wills Eye Hospital, Lecturer on Ophthalmology in the University of Pennsylvania. Professor of Ophthalmology in the Philadelphia Polyclinic and College for Graduates in Medicine, Philadelphia.

However perfect the eyes may be in other respects, comfortable vision cannot be enjoyed if the tears are retained in the conjunctival sac. The frequency of annoyance from lachrymal retention I believe is underestimated. We are too prone to think only of the large group of patients who suffer from epiphora consequent upon a more or less complete obstruction of the drainage system throughout its course or at some point in the canaliculi, sac, or nasal duct; or of the more pronounced cases of acute or chronic blenorrhœ. There is, however, a very large number of people who suffer more or less constant annoyance from a partial retention of the tears which rarely or never amounts to stillicidium, but which nevertheless keeps up a conjunctival hyperæmia from the constant soaking in tears. The retention may be so slight, or may have come on so gradually, as not to have fixed the attention of the patient, who will come simply for relief from discomfort in using the eyes. My first lesson in this group of patients was learned now many years ago by the case of a medical friend, who came because of his inability to read with comfort, particularly in the evenings. His glasses were carefully adjusted, but without affording relief. There was slight catarrhal conjunctivitis, and too red caruncles, which persisted in spite of washes and various applications. He made no complaint of epiphora and there were no indications of trouble in that direction until one blustering day he came hurriedly from his professional rounds, and I witnessed for the first time his eyes suffused with the retained tears. The puncta were then recognized as extremely minute. These were at once dilated with a fine conical probe, the point of a syringe introduced and a warm solution of boracic acid thrown freely through the duct. A second treatment relieved him permanently of the annoyance which for months I had vainly striven to remove. Attention once called to these cases of concealed retention I was surprised at the frequency of their occurrence, and the readiness with which relief can often be given. The cause, however, is by no means always to be found in the contraction of the lachrymal punctum but perhaps quite as frequently in some irritation in the nostrils leading to a turgid condition of tissues in and around the nasal end of the duct. The study and treatment of these minor cases of lachrymal retention, led to some interesting observations regarding the punctum lachrymarum. In the attempt to dilate it I noticed that the probe was grasped as by a sphincter muscle. I suggested to my friend Dr. B. A. Randall, who was at that time associated with me in practice, that a careful anatomical study should be made of the part. Material was procured and the existence of a triangularly arranged series of muscular fibres were without difficulty demonstrated, a drawing and microscopical sections of which I here present. In cases where simple dilatation of this sphincter punctæ lachrymarum does not suffice the fibres should be nicked by means of the blunt pointed Weber knife, in the direction of the canaliculus. The fine tip of a syringe can then be inserted without difficulty, and many cases of a more serious type of disease than the one above described can be treated by this means alone, the duct being treated by syringing with a variety of solutions instead of by probing and syringing combined.

By these experiences I was convinced that a more conservative treatment of disease of the lachrymal passages than I had before employed was sufficient in a large number of cases. It was possible to thoroughly cleanse the lachrymal sac and to inject any desired application for the relief of the inflammation of its walls, through the dilated or enlarged punctum, without slitting the canaliculus.

It is not intended by this to imply that all cases of lachrymal obstruction can be treated successfully without the use of probes, but that simply I have by this means been able to relieve a certain number of cases which it had been my practice to treat by the method of Bowman. This experience has, however, had the additional effect of introducing a more conservative management of even the severer forms of lachrymal disease. It is probable that we have been too prone to draw analogies between closure of the lachrymal passages and urethral strictures, and have in consequence adopted the same theoretical considerations as a basis of treatment. The peculiar anatomical arrangement of the canaliculi and their relation to the common duct by which the tears are conveyed into the lachrymal sac, should not be thoughtlessly disturbed by slitting the canal up to its orifice at the sac. I do not think this can be done without in a measure disturbing the physiological function of this admirable apparatus. At no time should the incision be carried further than the beginning of the common duct. This will suffice for the insertion of any probe which it is wise to pass through the bony duct, except in comparatively rare instances where the duct is much larger than the average as found in the dried skull.

In those cases where probing the duct is needful, the disease has usually been of long standing and has resulted in a more or less uniform thickening of the lining membrane, which has either partially or completely occluded its lumen. The same patient will frequently exhibit great variation in the degree of occlusion. During acute exacerbations the closure is complete and the sac will be distended by the accumulated tears, mucus, dust, etc., which is swept into it from the eye, or by the secretions from its own walls, while at other times the tears find their way into the nose with difficulty through a much narrowed duct.

The surgeon will usually be consulted for the first time when the annoyance is exaggerated by the acute conditions fastened upon a chronic trouble. The passage of the probe at such times is often necessary, and always a temptation to the surgeon, but when done should be undertaken with caution, since the inflamed mucous membrane lining the irregular bony walls of the duct is not only tender but is liable to fold in front of the probe and be perforated or torn, an accident which invariably retards the progress, makes the patient worse and complicates the subsequent treatment. I have again and again seen permanent injury result from this accident. Under these circumstances if the probe does not pass with the exercise of mild force I have desisted from any violence and for a few days treated the sac by syringing, paid careful attention to any trouble in the nostril, and if reaction was marked, applied hot water compresses to the side of the nose and over the sac. *When the acute stage has subsided the probing is* again attempted. A few drops of a 4 per cent. solution of cocaine thrown into the sac, after thorough cleansing, will not only relieve the pain from the probing but by contracting the turgid tissues permit its readier passage. It has been my habit to pass a probe sufficiently large to fit closely and allow it to remain for half an hour. After a few minutes a "throbbing" sensation in the region of the duct comes on which later disappears. The probe should then be withdrawn, and the duct thoroughly washed with a warm saturated solution of boracic acid, or Dobell's solution, and this followed by some astringent. I employ a solution of silver nitrate gr. j., f℥i, or a light wine-colored solution of iodine. This can be prepared by a drop or two of tinct. of iodine, or Lugol's solution in a half ounce of distilled water. Weak solutions of tannin are often useful.

In *acute* blenorrhœa of the sac, if seen early, hot water compresses are directed and if possible the sac flooded with corrosive sublimate solution $\frac{1}{8000}$, or what is often better, by solutions of blue pyoktannin. If the swelling is great and suppuration evident, the sac is opened in the usual manner and washed with the sublimate solution or pyoktannin through the incision, and hot water compresses continued. As soon as the swelling subsides the canaliculus is opened and the probe passed into the nose. The incision on the face rapidly closes and the closure of the duct which usually precedes the acute blennorrhœa treated in the manner above described. By these means I think it is possible to avoid the painful and I believe often injurious treatment by incision or by passing large probes with the idea of stretching or rupturing strictures of the duct. While by these means immediately good results are marked the closure recurs in a worse form than before. I have in a few cases seen narrow paper like strictures in which such treatment was indicated. In only one case have I ever felt justified in incising a stricture. In that instance it was a thin elastic membrane at the bottom of the sac. I long ago pointed out that the proper office of the probe is to place the thickened membrane under pressure for the time between the probe and the bony walls of the duct, and by this means hasten the absorption of inflammation products, much as the thickened edges of an old ulcer of the leg were removed by strapping.

The conservative management here urged, finds added force when we consider the etiology of this troublesome and frequent affection. Sudden onset of inflammation leading to obstruction of a hitherto healthy duct and sac has in my experience been rare. Inquiry will usually elicit the fact that the acute blenorrhœa is usually fastened upon a long standing case of more or less complete obstruction. Our task therefore is to discover the cause of the chronic disease.

I recall one case which may be regarded as an exception to this rule. A man in middle life came for relief from epiphora. The closure seemed quite complete, the parts were inflamed, and any attempt to pass the probe was extremely painful, and aggravated his trouble. Inquiry about his health discovered a syphilitic node on his scalp which had been incised by a physician who had mistaken it for an abscess. He had had the initial lesion several years before, had a syphilitic child, and his wife had had two miscarriages. All active local treatment for his lachry*mal trouble was omitted and the mixed internal* treatment prescribed under which he made a rapid and complete recovery from the lachrymal disease.

A frequent cause of the affections of the duct is to be found in the nose. I have often surmised that certain deformities of the bony duct may be associated with the frequent deformities of the bones of the nose. In a few instances this has seemed almost a certainty, but I have not had opportunity to demonstrate it upon any anatomical preparation. A very cursory study of any series of skulls, however, reveals great variety in the size and form of the duct. *It is* certain that in a considerable percentage of cases the lachrymal disease does not improve until attention is paid to the nostrils. I recall the case of a gentleman in middle life, suffering from epiphora, whom I treated in 1879. He was a large muscular man, in good health. Bowman's probes of medium size passed with but little difficulty through the duct. There seemed no reason why his epiphora should exist. Incidentally he called my attention to some trouble with the corresponding nostril which he hoped could be relieved. *I discovered a broad superficial ulcer on* the floor of the nostril, which spread itself around the orifice of the lachrymal duct, and over the anterior end of the inferior turbinated. This rapidly healed under a few applications of silver nitrate and the epiphora disappeared. Since *then the nostrils* have been subjected to inspection in all cases of lachrymal trouble. The frequency of the association of epiphora with various forms of nasal trouble will, I am sure, surprise the surgeon who has not investigated it as a routine matter.

It is by no means sure, however, that in all cases of such association that the lachrymal disease is an extention upwards *of the inflammation in the nos*tril. While this I think is unquestionably true in some cases, as has been *demonstrated by Dr. Harri*son Allen, and in my own practice many times, and quite recently by Dr. Geo. E. de Schweinitz in *a most* instructive group of cases presented to the Philadelphia County Medical Society, it is altogether probable that in certain other cases the trouble in the nostril is secondary, being caused by the absence of the tears, which serve the purpose of cleansing, and keeping the parts moist. It is folly to probe a lachrymal duct day after day, so long as its lower end opens into the infectious accumulations of a diseased nostril without at the same time giving proper attention to the existing nasal affection. The lachrymal diseases of childhood are ordinarily of this class.

In a still larger group of patients the lachrymal retention is apparently due to a persistent hyperæmia and turgidity of the mucous membrane, common alike to the conjunctiva, caruncles and lachrymal apparatus. In these cases but little is to be gained by any method of treatment directed to the drainage system alone. It will be found that this condition is another link in the chain of symptoms produced by eye strain, just as blepharitis ciliaris is due to the same cause, as was pointed out by Roosa in 1876.

In some collated, but not yet published statistics, I have shown that in 86 per cent. of all cases of blepharitis it had been found necessary to correct some existing error of refraction or muscular balance. In my paper on incipient cataract, read before the Section last year, I pointed out the large percentage of epiphora associated with the inflammatory conditions of the internal tunics of the eye. In a word, this hyperæmia of the external tunics, including the lachrymal apparatus, is often but the outward expression of intra-ocular conditions. The refraction errors and muscular anomalies are the most frequent cause of the turgid choroidal and retinal circulation. It is in this large group of patients that we find lachrymal retention so common. Given the tortuous uneven walls of the average nasal duct, line it with an engorged mucous membrane, and it is easy to mistake a bony prominence in the duct, for a stricture, especially when it is encountered at the end of a lachrymal probe. This is particularly true where we are led to anticipate the existence of a stricture because of the retained tears. We have here all the conditions for the establishment of a so-called vicious circle. An engorged membrane partially or wholly closing the nasal duct retards the onward movement of the tears, containing as they do in suspension, the mucous and dust from the conjunctiva and cornea, and the excreted products from the interior of the eye. The presence of this accumulation aggravates the existing local conditions, and it would be just cause for surprise if nutritional changes in the mucous membrane of the drainage system did not supervene, and more or less complete closure of the duct result through thickening of the membrane.

That this reasoning is not at fault, is substantiated by abundant experience. Many cases might be cited in demonstration. The following will serve as the representative of a large group which might be brought forward:

A. A. B., æt. 60. In good general health, a wealthy merchant, has been annoyed by epiphora for twenty years. Now worse, now better, but never absent, but much worse of late years. He has been a life long victim to attacks of sick headache and "weak eyes." He is a great traveler, and a man of broad culture and general intelligence. Both inferior canaliculi had been slit by Abadie, and he has been treated by probing and syringing many weeks at a time in several European cities by surgeons of great celebrity. He had given up all expectation of relief from his epiphora, but came for some advice about his reading glasses.

O. D. V=6÷xxx+1.25c. ax. 180°. V. 6÷vi; O. S. V.=6÷xviii +.65c. ax. 30° V. 6÷vi. The ophthalmoscope revealed a large semi-atrophic crescent embracing the temporal margin of both optic nerves, the choroid was woolly in the periphery, and in many places honeycombed.

The tarsal borders of the lids were red and thickened, the retro-tarsal folds and caruncles swollen; the eyes were suffused with tears. No. 3 of Bowman's probes passed tightly, but smoothly, through the nasal ducts, and fluid passed freely into the nose. He was given a collyrium of boracic acid to use freely with an eye cup, and a solution of homatropine to be used three times daily. The eyes were to be protected by smoked glass in bright light, and all use at near work avoided. The general conditions rapidly improved under this regimen and the daily treatment of the tear ducts. In a week the correcting glasses were ordered for constant wear, and a suitable combination prescribed for reading. In a month his epiphora had disappeared, he had no return of his headache, and his visits ceased. In six months he returned with a slight recurrence on the right side. His glass over this eye no longer gave him normal acuity of vision, and it was found necessary to change the axis of the cylinder from 180° to 15° and to make it slightly stronger when the retention of tears again promptly disappeared.

Many cases of like import might be recorded if it were needful to enforce still further the wisdom of conservatism in the management of an affection depending upon what at first sight might seem a remote etiological factor.

Discussion.

Dr. H. Gradle, Chicago:—In connection with diseases of the lachrymal passages our treatment and prognosis can only gain in certainty by a strict discrimination between the different forms of disease. This is not sufficiently recognised in the text books, although the speakers who have preceded me may have pointed it out. We must exclude all cases of reflex lachrymation without disease of the ducts. As a rule we can get the distinguishing criterion from the patient, where the duct is open the tears run *through the nose* when the eyes water. If the patient does not give this history, we can test the patentcy of the duct with the syringe or probe. Generally that is superfluous. In speaking of disease of the lachrymal passages, I exclude all these cases of reflex lachrymation with patentcy of the duct, and refer to those only where the duct or sac is at fault.

The text books speak of two classes of disease of these passages: 1, stricture somewhere in the duct or sac. 2, suppurative dacryocystitis; but they make no great distinction in treatment. These two classes are not identical and can be thoroughly separated in every respect. Stenosis of some part of the tear passage, does not endanger the eye from infection. There is nothing but stagnation of tears. On the other hand suppuration of the tear sac is not necessarily accompanied by stenosis, although it usually is. I have often been astonished to find very little resistance in entering the suppurating tear duct with the knife. Moreover, a point which is not commonly known is that in small children suppurative dacryocystitis can be cured without any operative interference simply by expressing the purulent contents of the sac regularly for a few weeks in succession.

In looking over my experience for the past two years, I find that the cases of disease of the lachrymal passages presented one or the other of two different types. There is scarcely any connecting link between these two classes. One class of patients state that the eyes water only when out in the wind or when they use the eyes severely. In the other type the eyes water all the time and we see that the internal canthus is suffused with tears during the entire examination. The prognosis in the two classes is entirely different. What the pathological differences are, I am not prepared to say, but I can make this clinical distinction that in one class, there is lachrymation only from external stimulation, while in the other class there is continued lachrymation, evidently from some irritant point either in the nose or lachrymal passage. The first class of cases get well with very little treatment. If we split the duct freely in this class of cases, a single operation will be sufficient. I have also probed and syringed but have an impression that these procedures are often superfluous. In cases of non-suppurative stenosis of the duct, I find that one, two or three sittings with electrolysis are sufficient, provided the eyes water only in the wind. On the other hand if the eye is continually suffused with tears, I have learned to regard the prognosis as very grave. A large proportion of these cases can be cured, but we cannot guarantee that there will not be a relapse. In other cases we cannot even cure the lachrymation temporarily if the patient does not continue treatment a very long time. We can gain a great deal by paying attention to the nose, but even with that many cases of the second type can not be absolutely cured.

Dr. H. M. Starkey, Chicago:—I was particularly interested in Dr. Risley's paper, because some of the points made in the paper were the important points to which I had intended to call attention had I been able to prepare the paper announced upon the programme. For the past eight years, I have found it advisable to use the knife and probe less than formerly and the syringe more, and have found it unnecessary in many cases to slit the canaliculus which is so often done as a preliminary to the treatment of the nasal duct. I was pleased to see in Meyer's work that he condemns this as a routine treatment. It is certainly very easy in a large proportion of cases to so dilate the punctum as to allow easy ingress for a No. 7 or No. 8 Bowman's probe. Usually the tissues at the inner part of the eye are sufficiently lax to permit of the turning of the probe. If this can be done, it is of advantage as it does not produce mutilation.

When we come to the treatment of the nasal duct and the lachrymal sac, we have to note the different varieties of disease there present. The remarks which I make apply particularly to cases of catarrh of the nasal duct and lachrymal sac. We have here a condition different from that found in stricture of the urethra, to which these cases have been compared. We have a small bony canal with its periosteum and connective tissue lined with mucous membrane. These tissues very nearly completely fill the lumen of the canal, so that there is no patulous canal, or a canal through which a large volume of fluid can flow at any time, as in the urethra. Here a slight degree of swelling will necessarily close the canal against the passage of tears. In other similar conditions we treat the case mainly by topical applications to the inflamed mucous membrane, and if practicable this seems to me to be the most rational treatment to employ here. While in many cases, the probe is necessary, I have found almost uniformly that frequent probing is unnecessary, and the point which I make particularly and which has not been brought out here, is that we should teach the patient as early as possible to wash out the lachrymal passage for himself. They almost invariably say that they cannot do it and it is something of a trick but in front of a glass they can soon learn to introduce the nozzle of the syringe, and then they soon learn to do it without the aid of the glass. If this is done frequently and antiseptic solutions are employed, the cure is much more rapidly attained. Afterwards, the patients continue this treatment at home, the injections not being so frequently repeated.

Of the utmost importance to the patient is the choice of lachrymal syringe. The easiest for the patient to use as well as the simplest and cheapest is the ordinary glass medicine dropper with point so drawn out as to easily enter the dilated punctum. Armed with this instrument I cannot recall a case where the patient has failed in his attempts to irrigate the lachrymal passages.

Dr. George M. Gould, Philadelphia:—The last speaker recalls to my mind a little point. Some of you may not have seen the last number of the *New York Medical Journal*, in which I have described a simple method by which in epiphora, etc., the patient can treat himself. The head is canted back and the inner canthus filled with an antiseptic and astringent solution. Then, with the finger pressing on the sac, it is emptied. When the finger is removed the sac expands, and the fluid is drawn in. Then pressing back towards the nose, some of the antiseptic fluid is forced into the duct. By repeating this process, the duct becomes antisepticized. I have had excellent success with this method. One lady who had had dacryocystitis for about sixty years, came back in one week cured. There is one thing that it is well to bear in mind: Never destroy a physiological structure if you can help it. No one seems able to describe the function of the puncta, and we therefore act as if the puncta had no function. I think that it has a definite function, and that we should be slow to injure the puncta, for slitting destroys their function forever. The function of the puncta is, I think, to serve as sifters of dust, etc., preventing their entrance into the duct, and we should therefore hesitate before destroying them.

I rose, however, more especially to call attention to the method which I have described. Dr. Risley has demonstrated that the duct should never be injured by a probe being crushed into it. In that way cases are made obstinate by the contraction of cicatricial tissue. I have no doubt that in a few years the probe will rarely be used in any case of duct disease. If there is stricture, the method that I have described will do no good. If functional, as nine-tenths of duct troubles are, the result of slight inflammation closing the capillarity of the tube, this method differentiates it, and if it cures it that is all that is needed. If it does not cure it, cutting may be resorted to, as advised by my friend Dr. Thomas. I think that in the future, the two methods of treatment will be, the method which I have mentioned, and incision with a proper knife.

Dr. R. Tilley, Chicago:—The point advanced by Dr. Gould is an important one. I do not know that I have ever seen anything in regard to the function of the puncta, but it has seemed to me that they act rather as favoring capillary attraction than as sifters of dust, and that by this capillary attraction, the tears are passed down more readily than by a larger canal. For this reason I have interfered with the puncta as little as possible. If they are to be destroyed at all, I would rather do so by a clean cut than by stretching. I do think that we should avoid any disturbance of the anatomical character of the puncta as much as possible.

It does seem amazing to listen to the reports of cases of excessive lachrymation as cured by various methods. It seems to me almost as impossible to cure by the simple means referred to some of these cases of excessive lachrymation, as to make the waters of the Mississippi go down the channel of the Illinois River.

Dr. G. E. de Schweinitz, Philadelphia:—I have listened with pleasure to the scholarly paper of Dr. Gradle, and desire to refer to one or two points in this connection. He calls attention to the condition of the optic nerve in certain atrophic conditions of the nasal cavity. This relationship has received some notice in Germany, and my own attention has been called to it in Philadelphia by Dr. Harrison Allen. In some patients affected with atrophic rhinitis, an examination of the eyes will reveal distinct discoloration of the optic papilla, and although there may be no deterioration of central vision, there is often decided contraction of the visual field. This contraction may affect the form fields, or be limited to the color fields alone, and the contraction will usually be found to be greatest in the eye on the same side in which there is the most marked atrophy of the tissues in the nasal chamber. I understand very well what a large personal element enters into the taking of color fields, and how readily mistakes may occur, but if it is conscientiously done, repeated a number of times and, if necessary, controlled by independent observers, very trifling changes may be detected and very interesting results achieved.

Dr. Gradle's classification of the various causes for epiphora is interesting. In this connection I would like to call attention to the fact, well known, to be sure, but which often escapes attention, that epiphora may be one of the ocular symptoms, very well marked in cases of locomotor ataxia. I have sometimes seen it when other characteristic phenomena, for example, the Argyll Robertson pupil, temporary diplopia, insufficiency of convergence, anæsthesia in the area of the supraorbital nerve, and the early discoloration of the optic papilla, are absent.

Dr. Thomas, to my mind, has presented a strong argument in favor of stricturotomy in certain cases of obstructive disease of the lachrymal passages, and I am particularly impressed with the valuable points he has brought out, and with the ingenious knife which he has devised and exhibited. I hope when he closes the discussion he will state a little more explicitly the exact method of the introduction of this instrument.

Dr. Gould's suggestion, it seems to me, is worthy of careful investigation. In curious confirmation of what he says concerning the *habitat* of the gonococcus is the well known fact, especially dwelt upon by Horner, that gonorrhœal ophthalmia almost never produces dacryocystitis, because the germs do not find a favorable soil in the mucous membrane of the duct and sac. An exception to this is the association of purulent ophthalmia and purulent disease of the lachrymal sac in connection with certain exanthematous diseases, but then in these diseases there is also a rhinitis, which is probably the primary factor.

Dr. Leartus Connor, Detroit:—I have not had the opportunity of hearing all the papers, and perhaps the points which I wish to make have already been referred to. In the little note that I made yesterday, I called attention to one case in which exophoria produced distinct, long-continued rhinitis. I have seen a number of cases in which the canaliculus had been slit and the duct treated with probes for a length of time, without satisfactory relief, entirely cured by the relief of an existing eye strain. In managing a case of epiphora, I first remove the eye strain. A large proportion of the cases in the early stages are relieved by removing this source of irritation to the lachrymal apparatus. I accept the view that if it be possible to maintain the anatomical and physiological structure of the lachrymal passages, it should be done. I have therefore followed the line of treatment referred to by Dr. Gould, and thus relieved a certain proportion of cases. Finally, we come to a class of cases where the disease is not relieved by the measures mentioned, and then the knife and probes have done me great service, and I should be loath to throw them aside. I have had the greatest satisfaction in the use of Williams' probes, but it is extremely difficult to procure these made in the proper way. The probe should be stiff and elastic, so as to bend without tearing the tissues. With these probes I have been able to pass through strictures of the lachrymal passages without injury to the tissues, a thing I could not have done so well with the stiff Bowman's probe.

Dr. Charles Hermon Thomas, Philadelphia:—In regard to the parallelism between the conditions found in urethral surgery and in that of the lachrymal duct, of course it is easy to force the comparison too far. The conditions are not identical, yet in some respects they are parallel. There is one point of likeness however, which may be stated emphatically, and that is that in treating stricture of the urethra, every good surgeon considers it all but criminal to make a false passage, and the same is true in regard to stricture of the lachrymal duct.

If there is one thing more than another which should be borne in mind in carrying out the plan which I have suggested, it is to *take time* to get though the stricture by means of dilatation, and not by forcing. No surgeon would think of making enough pressure to force a false passage in the urethra. He would repeat the attempt, sitting after sitting. In trying to get through these strictures I take all the time that may be required. I try first to coax through by the Williams' probe. If it does not pass, Anel's probe is to be tried. If this fails to find a passage, I wash the duct out with the syringe and tell the patient to come the next day. After a way through has been found the conical end of the stricturotome is to be introduced, and using it persistently as a dilator, it is passed through the stricture. Then a draw cut, not a cut by thrusting, is made. The incisions are to be made laterally and in front. In this way it is impossible to do harm.

A particular point is to be noted in regard to slitting the canaliculus and the opening into the sac. One gentleman asked if I had ever known an instance of shrinking of the opening into the sac. I have known such cases. This trouble was met with when I used the Weber knife. I now use a director and Beer's knife, pass it along until the knife has entered the sac completely, then withdrawing elevate it a little and cut upwards making a free opening in the sac. There is no more danger of such an opening closing than of the canaliculus closing.

I agree with all that has been said in regard to Williams' probes. As to Bowman's probes, if they are to be used at all they should be provided with conical tips.

Dr. Samuel D. Risley, Philadelphia:—I have but little to add to this interesting discussion, but am much gratified at the tendency to conservatism manifested by the remarks already made. What I wished to enforce in my paper was the possibility of treating these forms of disease without recourse to the violent measures which were employed during the early days of my ophthalmic career. I distinctly remember seeing large probes passed forcibly through the bony duct, which could have no other result than crushing the bone and doing permanent injury. Even in later years, I have seen cases where I felt sure that the existing form of the disease was due in large measure to the violent methods of treatment to which the duct had been subjected. I have had no experience with the slitting of so-called strictures of the duct. As I pointed out in the paper, I think that stricture in the ordinary sense, that is a closure of the duct at one point, is comparatively rare; that the closure is due to more or less uniform thickening of the lining mucous membrane, and reasoning *a priori*, to pass a knife through this, however gently, and cutting it must leave a scar in the mucous membrane, and every scar is an injury to the tissue. This is simply reasoning without experience, however, and I have no doubt that Dr. Thomas's observations have been accurate and thoroughly conscientious, and do not criticise his methods. It has always seemed to me to be more rational to get rid of the thickening of the duct by gentle means.

I was interested in Dr. de Schweintz' remarks in reference to the narrowing of the field of vision. I did not hear Dr. Gradle's paper, but judging from the discussion I think that he alludes to intra-ocular conditions found in association with nasal disease. I have seen a number of interesting things in this line and now have under treatment a young woman with impaired central vision and much contracted field both for form and red and blanching of the outer half of the optic nerve. I had seen her some years previously on account of a small coloboma of the nerve sheath. She came back with the condition described. Her father had had hæmorrhagic glaucoma, for which I did iridectomy and subsequently had to remove the organ. We can therefore understand what great anxiety must have been caused by the failure in the daughter's vision. I could find no intra-ocular cause for it. She also had violent hemi-crania. I examined the nostril and on the corresponding side found the cavity quite thoroughly occluded by hypertrophic tissue. After a few days' treatment in which the hypertrophy was removed, vision improved, the field for form and red became almost normal. The central vision also improved and the hemi-crania disappeared.

Dr. G. A. Aschman, Wheeling, W. Va:—I was much pleased to learn of the advocacy of conservative treatment. I have always tried to avoid slitting of the canaliculus wherever possible. There is one point which should be emphasized to the profession generally. It has been the experience of every one to have a patient referred to him after the family physician has slit the canaliculus, generally he does not use probes. In the majority of cases this fails to give relief and the patient is sent to us. Often a great deal of harm has already been done. As Dr. Tilley thinks, there is a capillary attraction here which is lost when we cut the puncta.

In regard to the point with reference to gonorrhœa passing through the nostril to the eye. I was struck by the point all the more because in one of my cases after closing the puncta on one side, secretion seemed to increase on the other side. There is undoubtedly some connection between the two.

In regard to closing the puncta to prevent inoculation from the lachrymal sac, I would state that in speaking with Dr. Knapp, he said that he had used the electro-cautery but had not always succeeded in closing the puncta sufficiently. So far I have had no difficulty if it is thoroughly done after treating by injection the canaliculus and sac. There has been firm adhesion in all cases. So many eyes have been lost in this way that it is important that we should find some reliable means of excluding infection from the sac.

Dr. George M. Gould, Philadelphia:—I only wish to add a word in regard to Dr. Conner's case. The reports of such cases are often looked upon with suspicion. If there is anything certain it is the fact of the existence of reflex neuroses. I wish to support the case cited by Connor by a case of my own. Mr. T., a well educated gentleman and one who has not the least sign of hysteria, finds hat whenever he wears a stronger myopic lens given for temporary use than the one ordered "for constant use" he will have all the symptoms of an intense common cold. In two hours the nose will become congested and run, the voice will become hoarse—in a word, there will be all the symptoms of an acute coryza. Putting on the weaker glasses these symptoms will in two hours disappear. This has been repeated so frequently that there can be no question in regard to it.

INSUFFICIENCIES OF THE OBLIQUE MUSCLES AND HOW TO CORRECT THEM.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY G. C. SAVAGE, M.D.,
OF NASHVILLE, TENN.
PROF. OF OPHTHALMOLOGY AND OTOLOGY IN THE MEDICAL DEPARTMENTS OF THE UNIVERSITY OF NASHVILLE AND VANDERBILT UNIVERSITY.

In the *Archives of Ophthalmology*, Vol. xx, No. 1, 1891, I announced my discovery of "Insufficiency of the Oblique Muscles." I closed that paper by saying of the nervous symptoms brought about by that state: "I can see no hope of prevention or cure." On the 17th day of May, 1892, while a patient was before me whom I had known to be a sufferer from this condition for two years, and to whom I had often said, "There is not now, nor can I see how there ever can be, any relief for this trouble," a thought of the proper means of correction dawned upon me. I at once applied the newly thought of principle in this case, and with the most gratifying results. Of this case I shall have more to say before closing this paper.

Before setting forth the treatment I will refer to the condition itself, and the proper means of detecting it. In doing this, since I cannot do better, I quote from my paper published in the *Archives:* "Every ophthalmic surgeon, however skilled in correcting errors of refraction and in operating for the different known forms of heterophoria, has had cases of eyestrain for which he could do but little. In investigating a few such cases during the last six months I have found the cause to be a want of equilibrium on the part of the *oblique muscles.* The detection of this condition is easy. I place a double prism (my modification of the Maddox prism) before one eye, the other for the moment being covered, and ask the patient to look at a horizontal line on a card held 18 inches away. The effect of the double prism (each 6° base in), so placed that the axis is vertical, is to make the line appear to be two, each parallel with the other. The other eye is now uncovered, and a third line is seen between the two, with which it should be perfectly parallel.

"While a change of the position of the axis of the double prism from the vertical towards the horizontal will alter the distance between the lines, their direction will be unchanged, hence no loss of parallelism. This fact admits of a little carelessness in the placing of the prism in the trial frames, though the axis should be vertical, so as to give the maximum distance between the two extreme lines.

Fig. 1.

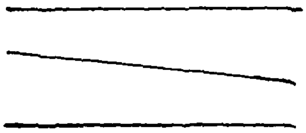

Fig. 3.

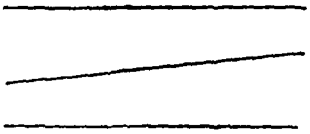

Fig. 2.

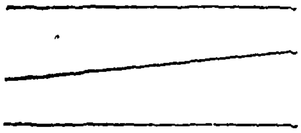

Fig. 4

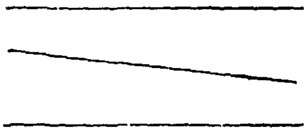

Fig. 5.

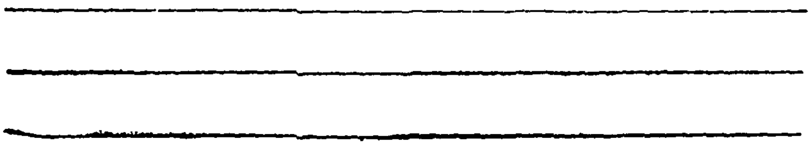


"If there is a want of harmony on the part of the oblique muscles, this test will show it at once in a want of parallelism of the middle with the two other lines, the right end of the middle line pointing towards the bottom, and the left end towards the top, line, or *vice versa,* depending on the nature of the individual case.

"In my investigations I have always considered the eye before which *no prism is held as the one* under test. With the double prism before the right eye, the patient is asked about the position and direction of the middle line. It may be nearer the bottom, thus showing left hyperphoria; or again, it may extend farther to the right than the other two and not so far to the left, thus showing exophoria; or *vice versa,* showing esophoria. If the right ends of the middle and bottom lines converge while the left ends diverge, the superior oblique of the left eye is at once shown to be in a state of underaction. Fig. 1 represents such a test of the left eye. Fig. 2 shows a test of the left eye when the inferior oblique is the too weak muscle. Fig. 3 represents a test of the right eye, the loss of the parallelism between the lines *being due to underaction of its superior oblique, and* Fig. 4 the same condition of the inferior oblique of the right eye. Fig. 5 represents a test of both eyes when there is perfect equilibrium of the oblique muscles.

"As is well known, the function of the oblique muscles is to keep the naturally vertical meridians of the two corneæ parallel even when not vertical [except in cases of uncorrected oblique astigmatism as shown in Vol. i, No. 1, of the *Ophthalmic Record*]. This must be, or a troublesome form of double vision will result. If there is a perfect equilibrium of the obliques, this parallelism of the meridians named is maintained without trouble; but if the superior oblique of either eye be too strong for its inferior, or *vice versa,* the parallelism of the vertical meridians is preserved, and double vision prevented, only by excessive work on the part of the weaker muscle. This condition of the oblique muscles brings on, at longer *or shorter intervals, a train of nervous symptoms* f which, at present, I can see no hope of preventic or cure."

As can be readily seen, the condition described the was *symmetrical insufficiency of the obliques.* Up that time I had not seen, nor had I heard of, a case of *non-symmetrical insufficiency of the obliques*. Dr. Moulton, however, reported such a case in a letter[1] to the editor of the *Ophthalmic Record*. I had reasoned that such a condition would not give trouble, since the strong muscles would be allowed to act, thus revolving the two eyes in the same direction, but causing no disturbance of vision. I still believe this reasoning correct except in cases of corrected astigmatism. Such a case Dr. Moulton reported, asking for an explanation of the fact that it became necessary for him to rotate his 1.00 D. cylinders from 90° to 100°, in order that the patient might have comfort, when several examinations under atropia had shown that the axis of each cylinder should be at 90°. My explanation, published in connection with his letter, was that there was insufficiency of the superior oblique of her right eye and the inferior oblique of her left eye; that these weak muscles, at the times of the several examinations, exerted their full amount of power and thus kept the best meridians at 90°; that these muscles at other times, because of fatigue, could not exert the necessary amount of power, and thus allowed their stronger opposing muscles (the inferior oblique of right and superior oblique of left) to change these meridians from 90° to 100°. It was at such a time as this that the doctor learned that the axes of his cylinders should be placed at 100°. Comfort came to, and remained with, his patient as a result of this little procedure. It was good ophthalmic practice, and should be followed in all cases of astigmatism where there is *non-symmetrical insufficiency of the obliques*.

In *symmetrical insufficiency of the obliques* the case is very different, both in principle and practice. It is for this latter condition that I am now able to point out the remedy.

To illustrate clearly the principle and practice I will take up for study the case of J. B. M., age 35, whose case I was studying the moment the thought of the cure came to me. Two years ago he came to consult me about a headache that for a long time had troubled him, and which was growing more severe. He had been advised that it was probably due to eye-strain, and if so, it could be cured by properly adjusted lenses. A preliminary examination showed only a slight error of refraction. This he consented to have corrected, hoping that he would get relief, other means having failed. Under homatropine the following correction was given:

O. D. V. 20-xx with + .25 ⊃ + .25 cyl., ax. 155°.
O. S. V. 22-xx with + .25 ⊃ + .50 cyl., ax. 90°.

It was determined at the same time that he had left hyperphoria. It was also determined that he had insufficiency of both right and left superior obliques. He was told that all but the latter could be corrected; that he would get some, but not complete, relief by wearing his sphero-cylinder lenses, the left ground on a prism of ½° base down; that, at times, the insufficiency of the obliques would give him trouble, for there was nothing that could be done for this condition. I did tell him that if, when engaged in near work, he felt a headache coming on, he might cover one eye with a flap, thus doing away with the strain necessary for harmonious action of the muscles of the two eyes. This he tried occasionally, but found it very inconvenient to work with one eye only. His attacks of suffering were greatly lessened in both frequency and severity for some months, as a result of the elimination of some of the factors formerly constituting the cause of his suffering.

He wore his spectacles continually, but after awhile his headaches began to return. They grew more frequent and more severe until he became an almost daily sufferer. Not infrequently on going home from his office his wife would have to put him to bed like a child. He would occasionally take medicines prescribed by his family physician to relieve the severity of the attack.

At intervals, during the whole time, he would consult me. When complaining I would tell him that I believed that the then-active cause was the insufficiency of his superior obliques, and that I was powerless to do more than I had already advised. A few months ago I made a second examination of his eyes under the influence of homatropine, but only to find that the result of my former examination was correct. I did not have to urge him to wear his glasses, because he had learned that he was more comfortable with than without them.

On the 13th of May, 1892, he came to me and said that I must do something more for him; that he must have relief. Reminding him that I had twice investigated his eyes and each time found the same conditions, and had corrected all that was correctable, I told him that I was willing to try again, but that I was now as unable to correct the insufficiency of his obliques as I ever was. In the course of this conversation I told him if he had but one eye, he would not be a sufferer. Deciding that it would be four days before he could return for another examination, he went away. On the 17th at the hour appointed he came, and without hope of finding an additional means of relief, I undertook the investigation again. The results of former examinations as to lenses were confirmed. My study of the recti muscles resulted as formerly in finding a left hyperphoria of ½. With the remark, "We will now look into that incorrectable condition," I began to investigate the obliques. Placing the 6° double prism before the right eye, the left eye (the one under test) showed the middle line dipping unmistakably to the right, as in Fig. 1, thus showing insufficiency of the left superior oblique. Transferring the double prism to the left eye, the right eye showed the middle line dipping to the left, as in Fig. 3, thus showing insufficiency of the right superior oblique. Having stated again that nothing more could be done for him, in a moment the thought occurred to me that, if a cylinder were placed before the eye in such a way as to make the line incline still more in the same direction, on removing the double prism the weak obliques would have to act more than usual in binocular vision. I reasoned that this overaction being in the nature of gymnastic exercise, if conducted properly must develop the weak muscles, and thus be a source of relief to the patient. Leaving the double prism in front of the right eye, I placed a + 2.00 cylinder before the left, and revolving it so as to bring its axis to 135°, the middle line was seen to dip very much more to the right. I then turned the axis back to 90°, when the dipping was the same as when no cylinder was on. Turning the axis of the cylinder to 45°, the middle line was made parallel with the other two (this little procedure of placing the axis of a cyl. obliquely first in one direction, then in the other, and watching the effect on the middle line, will establish or disprove the correctness of the diagnosis). The diagnosis made and positively confirmed, I at once commenced the gymnastic exercise by placing a + 2.00 cyl. before each eye, the axis of the right at 70° and the axis of the left at 110°. The patient was asked to fix his vision on a candle 20 feet distant (the double prism had been removed). In three minutes the axis of right cylinder was turned to 60° and that of the left to 120°; three minutes later the axis of right was placed at 50° and that of left at 130°; and again in three minutes the axes were changed, the right to 45° and the left to 135°. With each turning there was additional demand made on the superior obliques, the maximum being reached when the axes were respectively at 45° and 135°. With each turn the patient could feel additional strain. The cylinders were allowed to remain in this position of maximum effect three minutes, when they were removed and the double prism test was applied. There was the slightest, if any, dipping of the middle line. Both patient and practitioner felt encouraged. He has returned daily for the *exercise*, which has been conducted every time in the manner above described.

On the day after the first *exercise* he resumed his office work, which requires almost continuous near use of his eyes, and has been absolutely comfortable up to this time—the end of the eleventh day, and not one dose of medicine has been taken. For the last three days, before beginning the *exercise*, the test when applied to either eye showed but little, if any, want of parallelism of the lines. His improvement has been rapid and remarkable.

I have now under the exercise treatment a little girl, age 15 years, whose trouble is insufficiency of the inferior obliques. The dipping of the middle line is to the left in the left eye and to the right in the right eye—just the contrary of what was found in the other case. The *exercise* in her case is carried on by revolving spasmodically the axis of the right cylinder from 90° to 135°, and that of left from 90° to 45°, the reverse of the plan in the first case. She does not bear the exercise as well as the first patient, but her improvement in five days is noticeable.

---

[1] See Ophthalmic Record, Vol. i, No. 4, 1891.

My records for the past two years show a number of cases of *symmetrical insufficiency of the obliques*, to all of whom I stated: "For this condition I can do nothing."

The condition is real, the treatment is rational and relief must follow. The condition is easy of detection and the insufficient muscle can be quickly located. The double prism before the right eye, the middle line is seen by the left (the one under test); if it dip towards the opposite (right) side, the superior oblique is insufficient (see Fig. 1); if towards the same side, the inferior oblique is insufficient (see Fig. 2). The same is true when the right eye is under test, as is shown in Figs. 3 and 4. In the treatment either concave or convex cylinders can be used; if the concave are used and the insufficiency is in the superior obliques, the axes must be placed in the lower nasal quadrant, if in the inferior obliques, then the axes must be placed in the lower temporal quadrant. If for the exercise the convex cylinders are chosen, the axes must be placed in the lower temporal quadrant for insufficiency of the superior obliques, and in the lower nasal quadrant for insufficiency of the inferior obliques. In either case the effect is increased as the axis is made to move from the vertical to the point of maximum effect, which is 45° from the vertical. The exercise may be commenced with a .50 to a 1.00 D. cylinder, and increased each day a .50 D. up to 3.00 D. The cases will be very rare that will require a stronger exercise cylinder than the last mentioned. The graduated exercise should be continued not longer than twelve or fifteen minutes daily. Each eye being affected, the exercise cylinders are placed before both at the same time.

Discussion.

Dr. H. Gradle, Chicago:—Any one taking the trouble to examine the eyes of healthy individuals as to the condition of the muscular balance can convince himself that in a large number of individuals, the muscular balance is not perfect when binocular vision is absolute. There occurs vertical and lateral, as well as the rotatory deviations, described by Dr. Savage. Whether these deviations are the cause of the eye strain and other nervous symptoms attributed to them by certain eye surgeons, is an open question and I do not think that this is the proper time to discuss that question, but I would ask whether any tests have been made to prove whether or not the symptoms of eye strain and nerve strain are due to the deviation. According to the theory, the muscles are strained in the interest of binocular vision, and if binocular vision is excluded the eye takes a position of rest. If one eye is excluded from work, there should be no eye strain. Has this experiment been made to determine whether the eye strain, headache, etc., were abolished by the use of one eye with the other excluded from light? I have done so in a certain number of cases of strictly latent deviation and found the test negative.

Dr. Charles Hermon Thomas, Philadelphia:—I have had some experience in the line which Dr. Gradle suggests. I have tried covering one eye where there were phoria faults and found negative results very largely; wearing the cover introduces a disturbing element. A better test is to correct the fault with prisms and note the results. Under these circumstances the answer is usually positive.

As regards the particular point raised in the paper, I made some tests according to the diagram of Dr. Savage in his publication of last year, and found that they held perfectly, but came to the conclusion that I could see nothing to be done in these cases. Exercise of the muscles of the eye with prisms has not yielded satisfactory results in my hands. The cylinders used as described by Dr. Savage seem to act as prisms do on the recti, and I should expect the same negative results which I have obtained from prisms used to exercise the other muscles. From an experience growing out of some hundreds of cases of graduated tenotomy I am satisfied that the latter may be expected to give much better results.

I did not mean to be understood as disapproving of the use of prisms for the direct compensation of defects made out. I have the greatest appreciation of them for this purpose, especially in the lower degrees. I do not believe, however, in the value of prisms as a means of exercise to permanently influence the nutrition of weak muscles.

Dr. Leartus Connor, Detroit:—My experience with the use of prisms differs from that of Dr. Thomas. Possibly the method of using partially accounts for this difference. I employ round prisms, so as to be able to shift them at any angle according as the weakness of any muscle may require. The prisms are set in ordinary spectacle frames that they may be worn constantly during a longer or shorter period as each particular case may call for. By such use of prisms alone, I have seen many cases of eye strain so completely relieved, that the patients were enabled to resume their ordinary duties, without the permanent use of any prism. It must be said that most cases of heterophoria are cured by the proper correction of their refraction. Such relief of heterophoria is most satisfactory. The class relieved by prisms just mentioned were those in which either there was no refractive defect, or it it existed, its correction left a distressing heterophoria. Another small class of cases require the constant use of prisms and experience such comfort and relief, that they will not part with them or consent to a radical cure by tenotomy.

In a fourth class of cases all the measures mentioned fail, and a more or less complete tenotomy is called for. Here the results I have found most satisfactory. I never do a tenotomy until convinced that spheres, cylinders or prisms are insufficient to give satisfactory relief. By their aid I have not yet failed to relieve the cases of insufficiency of the oblique muscles, described by Dr. Savage. It will give me pleasure to re-study the subject in the light of his interesting paper, and if the treatment suggested proves easier and more satisfactory, to accord him my cordial thanks.

Dr. G. C. Savage, Nashville:—One of the gentleman asks for proof that these muscle conditions can be properly charged with the suffering that we see. He wants to know if the correction of the error of refraction will not afford relief. I am before you a personal example on this point. I have a moderately high degree of astigmatism which was corrected some ten years ago. Before that I had sick headache. The sphero-cylinders which I wore relieved me of the pain above the left eye especially. From that time until eighteen months ago I would every week of my life, especially after I exercised myself in work, have a band-like feeling across my head from ear to ear. Dr. Stevens of New York, had told me that I had half a degree of left hyperphoria but I did not attach much importance to so low a degree; but I decided to have the left lens ground on a half degree prism base downward. There has never been that band-like feeling since. Eight years ago, I corrected the vision of a patient with hypermetropic astigmatism. I did not test for any muscular error. The sphero-cylinders gave relief for possibly two years. The suffering then began again and she finally lost the ability to read; and about two months ago she returned. She had about ten degrees of exophoria and I operated on her. There has been no suffering since I did the partial tenotomy of the rectus muscle.

Trying to use one eye is a source of trouble to any body. If we could get accustomed to it, heterophoria would be relieved by excluding one eye entirely. It has been claimed that when one eye was lost the other was stronger than the two had been. We now know why this is true. A simple prism will not exercise the oblique muscles in any position. The prismatic effect of a cylinder does exercise the oblique muscles as can be proven readily.

Hyposulphite Soda in Gastro-Intestinal Antisepsis.—According to Goll the abandonment of sodium hyposulphite in treating diseases of the stomach and intestines for other and newer remedies is a great mistake. In solutions it is far more efficacious than resorcin and all other stomachics used in the treatment of gastric and intestinal catarrh. Especially does it seem indicated in chronic catarrh: its effects in this direction are very marked.—*Pacific Record.*

EMBOLISM OF THE CENTRAL ARTERY, A THROMBOSIS? WITH REPORT OF A CASE.

Read in the Section of Ophthalmology at the Forty-third Annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY S. C. AYRES, M.D.,
OF CINCINNATI, O.

When the diagnosis of embolism of the central artery of the retina was made by V. Graefe in 1859, and so satisfactorily confirmed by Schweigge a year or two later by microscopic sections of the same eye, it seemed to have settled a hitherto obscure point. The pathological alterations coincided so exactly with the supposed cause of the sudden blindness, that no conditions were wanting to completely explain the case. The brilliancy of this case has not been dimmed by the passing years, for but few have been reported which have such clear cut points. In fact, subsequent investigations have shown that other pathological conditions may produce very similar subjective and objective symptoms, and it becomes a question of great interest to determine whether we are dealing with a case of embolism of the central artery or of thrombosis of the veins.

In 1874, the late Dr. Ed. G. Loring, of New York, reported in the *American Journal of Medical Sciences* five cases which had been designated as embolism by himself as well as by some of his colleagues, but where subsequent developments led him to change his opinion.

In his excellent Hand Book he discusses the subject in an exhaustive manner, and concludes by saying that in cases of so-called embolism, "too much significance has been laid upon the stoppage of the circulation by the importation of a plug formed at a distance, while not enough stress has been laid upon the mechanical actions regulating the supply of blood within the eye, as well as upon the conditions of the walls of the vessels themselves or their contents."

The ophthalmoscopic picture which embolism of the central artery of the retina presents, is familiar to you all, and I need not recall it. An empty condition of the central artery is prima facia evidence of an obstruction at some point, but is that necessarily an embolism? May it not be a thrombosis?

In Angeluccis' case it was shown that thrombosis of the vein caused occlusion of the artery by mechanical pressure.

Œdema of the retina, cherry red macula and narrowing of the arteries were all present here, yet the microscopic examination showed the arteries free from obstruction, and the disease limited to the veins. From a study of the recent literature on the subject, it seems that the opinion is gaining ground that many of the so-called cases of embolism are due to thrombosis of the artery or the vein. Is it necessary to wait for a post-mortem to settle these questions positively, or can we not by a careful differentiation decide while the case is still under observation?

Priestly Smith argues that spontaneous thrombosis of the retinal arteries may account for both the permanent as well as transient blindness. In *Oph. Review*, 1884, he differentiates spontaneous thrombosis as follows:

Previous attacks of transient blindness occurring in the blind eye as well as in the fellow eye, and associated with signs of disturbance of cerebral circulation at the onset of the blindness and with giddiness, faintness or headache.

The diagnosis of embolism so far as any systematic disturbances are concerned, is negative.

Michel, in 1878, in Vol. XXIV, *Graefes Archiv.*, reports seven cases of thrombosis. In one the microscopic examination showed that the lumen of the central vein was completely blocked by an organized thrombosis. The arteries were not diseased. He recognizes three degrees of obstruction.

1. Complete closure of the central vein associated with numerous hæmorrhages into the retina, and a grayish discoloration in the macula region with the usual cherry red spot.

2. Incomplete closure when all the conditions are much less intense, and 3, a simple stasis of the venous system with few ecchymoses and marked dilatation of the veins.

Hæmorrhages seem to be the most significant alterations in favor of thrombosis. They are more or less abundant, being dependent according to Michel in the degree of obstruction in the vein, and yet they are present in well authenticated cases of embolism.

Gowers says that thrombosis has been observed in the retinal artery with ocular signs identical with those of embolism.

Thrombosis of the central artery is reported by Parinaud (*Gaz. Med. de' Paris*, 1882), followed by cerebral softening. In this case there was sudden loss of vision, diminution in the calibre of both veins and arteries, œdema of the retina and hæmorrhages, and rapid development of atrophy of the disc.

Loring says that "all the cases of occlusion of the artery have been declared hitherto, by their authors at least, to be due to embolism in contra-distinction to thrombosis, but it must be admitted that *a priori* there is no reason why thrombosis should not occur."

In the discussion of a case of embolism of the left central artery by Dr. Oliver in the Trans. of the Am. Oph. Soc., 1888, Dr. H. D. Noyes remarked that in reality a large number of those cases are due to thrombosis, and this is proven by microscopic examinations. He said also that about the only typical case of embolism was that of Graefe.

What then have we to fall back on as positive evidence of embolism? The primary ophthalmoscopic appearance should not determine this point, but rather the secondary or remote conditions which follow sudden loss of sight—complete obliteration of a vessel, atrophy of the optic nerve, and total or almost total loss of vision.

Embolism is supposed to depend on organic valvular heart disease, and yet in Angeluccis' first case of thrombosis, the patient had organic heart disease and valvular softening, and yet the autopsy showed the arteries healthy and the disease entirely in the vein.

Allow me to present you in detail a case which came under my observation recently:

Mr. B., æt. 33, gave the following history, on March 22, 1892: he stated that he awoke this morning about six o'clock and at that time his eyes were all right. He then took a nap of probably half an hour, and when he awoke, his vision in the left eye was almost obliterated. I saw him about ten o'clock and then his vision was so reduced that he could only count fingers at 2'. His field of vision was entirely obscured except in a sector like space below, through which he could count my fingers at 2'. The retina presented an appearance very closely resembling embolism of the central artery. There was an opaque area of retina crescentic in shape extending from the disc to the macula both above and below. It was not so white as is sometimes seen, but presented more of a feathery appearance. The optic disc was normal in appearance, and no traces of an obstructed vessel could be seen. Neither the arteries nor the veins were altered in appearance. The macula presented a cherry red appearance, but no hæmorrhages of the retina were visible. The next day vision was 0.6, on the 24th 0.8, and on the 26th, four days after the attack, central vision was perfect. The field of vision gradually widened on both sides from below upward, and when last examined a few days ago, there was only a blank in the field directly upward. The œdema of the retina faded out in about a week, and the cherry red appearance in the macula in two weeks. Was this an embolism? probably not. Was it a spontaneous thrombosis according to Priestly Smith? Was it a thrombosis as is described by Michel of the third degree—a simple stasis? In this case the patient had been indulging in stimulants and tobacco freely for some months previous, and particularly so on the night before this attack occurred. Is there not a direct relationship between the engorgement between the cerebral and the retinal vessels and the œdema of the retina?

REPORT OF A CASE OF ZONULAR ATROPHY OF THE CHOROID.

Read in the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, June, 1892.

BY R. TILLEY, M.D.,

OF CHICAGO, ILL.

J. N. O., age 66 years. One of a family of two children. Father and mother lived to the age respectively of 63 and 81. No recognized defect in the eyes of father or mother. Father afflicted with a contraction of the subcutaneous fascia of palm of the hand, resulting in the condition known as Dupuytrien's fingers. Patient's brother, now dead, was afflicted in a similar way in the right hand, but only one finger was affected. Patient himself, who was for a great part of his life an English sailor, has marked, severe contraction of several fingers, involving both hands, clearly referable to similar condition of the subcutaneous fascia. He has now and has had for ten years at least, a remarkable intermittent pulse; remarkable in that there is a decided regularity to the irregularity. I took a tracing of it, but finding that it really failed to give any accurate conception of it, I have not thought proper to produce it. Patient has a son-in-law, a physician, who writes me that he observed this irregularity ten years ago. In order to get as definite a view as possible of the condition of the heart I referred him to Dr. R. H. Babcock, who reported as follows:

CHICAGO, May 3, 1892.

Dear Doctor:—Please pardon the tardiness of my report concerning Mr. Owen, whom I examined last Friday. The irregularity of his pulse struck me at first as being an example of the pulsus trigeminus, but on more extended palpation, it was found to intermit at regular intervals. Sometimes there was an apparent intermission due to a pulse wave that was scarcely to be felt. I then auscultated the heart while feeling the pulse, radial, and it seemed to me that at times the heart contracted without forcing a pulse wave all the way to the wrist, but as to that I am not quite positive.

There is no evidence particularly of extended arteriosclerosis, although his age would render that condition probable in a measure at least. There is marked evidence of heart degeneration. He says he sometimes has pain and stiffness in the joint of the right big toe, but without enlargement. He suffers also with great flatulent indigestion, which has been the case about ten years. There is such an absence of symptoms referable to the heart, that it seems to me his intermittency of pulse must be due largely to reflex causes. Very sincerely yours,

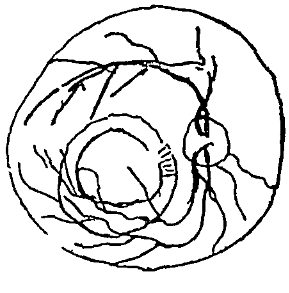
ROBERT H. BABCOCK, M.D.

He suffered some ten years ago from an excruciating pain —"a boring pain" which, as far as I can make out was referred either to the heart or stomach. The doctor in attendance, Dr. Heydock, now dead, confessed that he could not satisfy himself as to the cause of the pain. He suffers at times now from some pain in the lower part of the back, extending downwards in the region of the sciatic nerves. He has had two children and only two; one only is living. There is no evidence of lues that I can elicit. There is no evidence of renal affection.

The external appearance of both eyes is normal, with the exception of a certain amount of chronic conjunctivitis. No adhesion of the irides, but the pupils do not dilate under mydriatics *ad maximum*.

In both eyes there is incipient capsular cataract, both most pronounced in the infero-internal quadrants—the best eye, the left, giving the most evidence of cataract.

The curious feature which has induced me to report the case is the peculiar form which the degeneration of the choroid of the right eye has assumed. I have called it zonular atrophy of the choroid. The peculiar band of atrophy does not occupy exactly the position which it should occupy relative to the poles of the eyes to fully justify the appellation. It forms, however, a distinct band, the relative position of which will be best understood by the accompanying diagram. You will see that the band is represented a good deal wider at the bottom than at the top, and the part near the optic disc possesses quite an amount of choroidal tissue which clearly supplies the blood to the island of relatively normal tissue. In the lower part the sclera is plainly visible, traversed only by some retinal vessels. The edges of the pathological tissue are clear cut, not black, in places brownish, and the area embraces the macula.



After considerable patient observation I can detect no visible difference between the choroidal tissue forming the island and the general choroidal tissue. When the communicating bridges disappear the whole island of apparently normal tissue will disappear, and leave the sclera exposed throughout the whole area similar to the wider area below.

The sensations which he complains of are floating objects, a dark brown area in the centre and upper part of the field of vision—both of them sketched out for me on a piece of paper—and a continual whirl of different colors before the eyes, most manifest in the affected eye and more troublesome in a bright light. The colors he compares to the colors of the flower, the sweet william. Whether the whirling sensation complained of also in the relatively healthy eye is referable or not to pathological changes in the right eye, I cannot determine. I suppose that if such a sensation is due to the disturbed circulation of the choroid, the sensation would be shared by both eyes. I will add, moreover, that a very small patch of pigment, quite black, has been observed in the lower part of the fundus of left eye, the region corresponding to the region of greatest atrophic development in the eye under consideration. It will be interesting to observe if that peculiar subjective sensation will disappear with the completion of the atrophy of the choroidal bands now uniting the island to the remaining choroidal tissue.

Whether that spot of pigment in the lower part of fundus of left eye is the commencement of a similar process in that eye, it is impossible to divine. I have had the case under observation now for about five months, and I can observe but little change.

NAPHTHALINE IN THE TREATMENT OF WHOOPING COUGH.—The treatment of whooping cough by means of naphthaline fumigation is recommended by Chavernac (in *Bull. Gen. de Ther.*). About half an ounce of the drug is, on one or more nights, made to burn in a suitable vessel in the sick room, the windows and doors being tightly closed. The cough at once moderates, the dyspnœa and other symptoms are favorably influenced, and the attack is soon brought to an end. Complications may contra-indicate the employment of the remedy. Those individuals suffering with pulmonary tuberculosis cannot bear the treatment.

SECTION ON NEUROLOGY AND MEDICAL JURISPRUDENCE.

Chairman, Dr. Harold N. Moyer, Chicago, Ill.
Secretary, Dr. Geo. R. Trowbridge, Danville, Pa.

The Section met in the hall of the Young Men's Christian Association, Detroit, at 3 P.M., June 7, 1892, and was called to order by the chairman.

In the absence of the secretary, Dr. Trowbridge, Dr. W. J. Herdman, of Ann Arbor, Mich., was elected secretary *pro tem.*

1. The first order of business was remarks by the chairman of the Section, Dr. Moyer.
2. Paper by Mr. Henry A. Chaney, with discussion.
3. Paper by Dr. Comegys, with discussion.
4. Paper by Dr. Hughes, with discussion.
5. Paper by Dr. Mills, with discussion.
6. Paper by Dr. Kiernan.
7. Paper by Dr. Chaddock, with discussion.
8. Papers by Drs. Rockwell and Fell, with joint discussion
9. Paper by Dr. Howell, with discussion (paper not received).
10. Paper by Dr. Sanger Brown, with discussion.
11. Papers by Drs. Bremer and Lydston, with discussion.
12. Paper by Dr. Fuller.
13. Paper by Dr. Manley, with discussion.
14. Papers by Drs. Crothers, Dewey and Talbot, with discussion.

The following papers read by title:

1. Paper by Dr. Moyer.
2. Paper by Dr. Wright.
3. Paper by Dr. Mason.
4. Paper by Dr. Norbury.

REMARKS BY THE CHAIRMAN.

BY HAROLD N. MOYER, M.D.,
OF CHICAGO.

Gentlemen: The address which I had prepared on the organization of the work of this Section is no longer suitable. I had outlined in that address what I conceived to be the best organization to the end that we should develop our own autonomy to some extent on the lines adopted by the Section on Ophthalmology. But the action of the Association this morning in creating an Executive Committee for the Sections, and giving it power to formulate some general rules for the conduct of the Association in the future, has made my address somewhat inappropriate; therefore, I will not deliver it, but instead will briefly refer to a few points of an historical nature.

It was many years since Dr. Ray instituted a section on insanity in the American Medical Association, which was continued for some years and did good work. For some reason that section was finally discontinued and its work was merged into the Section on the Practice of Medicine. Thus, for a number of years—at least, more than a dozen—there was no special section for the discussion of neurological subjects.

In 1884, Dr. Quimby, I think, introduced a resolution creating a Section on Medical Jurisprudence. The following year this Section was instituted, and the Section held its first meeting in Cincinnati. We had then some six papers on the program and about four or five members to listen to them.

The following year the scope of the Section was enlarged by the addition of neurology, and at the Nashville meeting we had a fair attendance and a few excellent papers. The next meeting at Washington showed renewed interest in the work of this Section, twenty-two papers were read, and the attendance was large. From these small beginnings the work has gradually developed until we present you to-day a program containing forty-one titles, many of them from the pens of the most eminent neurologists in this country.

I think we can congratulate ourselves on the success of the work of our Section; one of the youngest, it has shown a vitality and growth that has in some cases outstripped its elders. I feel that without making invidious distinctions that I can especially mention the enthusiastic work of Drs. Hughes, Kiernan, Crothers, and Evarts. It is due largely to the persistent work of these men that we have achieved such a signal success; with such a past we can confidently look forward to the near future when the meeting of this Section will show as good work as is done by any similar body in this country. (Applause.)

RESPONSIBILITY IN WILL-MAKING.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third annual meeting of the American Medical Association, held in Detroit, Mich., June 7, 1892.

BY HENRY A CHANEY,
OF DETROIT, MICH.
PROFESSOR OF MEDICAL JURISPRUDENCE, MICHIGAN COLLEGE OF MEDICINE AND SURGERY.

It is and has long been the all but universal rule that one must be of sound mind to make a will that will stand. It is so laid down in the statutes of nearly all the States. If this rule were rigidly observed, many more wills would be set aside than are. But the courts have greatly relaxed it, so that absolute soundness of mind is now by no means a condition to the making of valid bequests. The old English law was that a single foolish word would spoil a will, and so recent a chancellor as Lord Brougham decided that any degree of mental perversion would be fatal. But when Sir Alexander Cockburn came to the bench, he changed the whole current of the English law on that point. In the case of Banks *v.* Goodfellow, 5 Q. B. 549, he stated in the clearest and most positive way the then existing rule and the reasoning that supported it. The rule was, that any degree of mental unsoundness, however slight, and even though it exercised no influence on the will and was wholly unconnected with the disposition the testator made of his property, was fatal to the will. And the reason was that the mind, though it has various faculties, is one and indivisible; if it is disordered in any one of these faculties—if it labors under any delusion arising from such disorder, though its other faculties and functions remain undisturbed, it cannot be said to be sound; such a mind is *unsound*, and testamentary incapacity is the necessary consequence. By way of answer to this, Sir Alexander reviewed in an elaborate opinion the condition of British and Continental jurisprudence on this point, and found it either unsatisfactory or superficial. Turning, then, to the American decisions, and especially to certain New Jersey cases, he commended the good sense of the American law, and said in his own convincing fashion, that if it were conceded that the only legitimate ground for denying testamentary capacity to persons of unsound mind is their inability to take into account and give due effect to the considerations which ought to be present to the mind of a testator in making his will, and to influence his decision as to the disposal of his property, it follows that a degree or form of unsoundness which neither disturbs the exercise of the faculties necessary for such an act, nor is capable of influencing the result, ought not to take away the power of making a will, or place a person so circumstanced in a less advantageous position than others. And later English cases have been decided accordingly.

To get the full force of the Lord Chief Justice's reasoning, it should be stated that the Banks whose will was in question in this case had once been unquestionably insane—had been confined in a county asylum, and when discharged had remained subject to certain fixed delusions. He had long had a deep aversion to one Featherstone Alexander, and though the man had been dead for years, Banks still believed he continued to follow and molest him; the mention of his name threw him into violent excitement. He also believed himself to be molested by devils whom he thought visibly present. At the time he made his will he had been having a succession of epileptic fits. But on the other hand, he managed his own limited affairs and was careful of his money. Notwithstanding his antecedents, and in direct contravention to what had been the law of England as laid down by her judges, Chief Justice Cockburn held that his will was valid.

A short report of a few of the more important recent cases in this country, relating to testamentary capacity, may be of interest, and possibly of some service as at least a basis for further inquiry. Their net result, however, as matter of law, if summed up at the outset, is that the more recent rule already explained remains substantially unchanged, and, if anything, receives a more and more liberal interpretation, and that the courts seem less and less inclined to interfere with wills on the score of mental unsoundness.

Bannister v. Jackson, 45 N. J. Eq. 702.—In 1887 there died at the German Hospital in Newark one George M. Bannister, who had made a will three years before by which he left his wife $500 in addition to her dower right, and his daughter a like sum, which was not to be allowed to get into the hands of her husband. Her husband, by the way, had been dead for two years. Bannister left the rest of his estate, which was all personal and amounted to $12,000 or $14,000, to four brothers living in England. He had been for twelve years a chronic drunkard, who saw strange sights, whose hand trembled continuously and who when sober, was nervous, sleepless and irritable. He died of chronic alcoholism, and his widow and daughter resisted the probate of his will on the ground that his condition deprived him of testamentary capacity. The Prerogative Court, however, found from the testimony that he had managed to keep his business together and to sell it to good advantage, and that some time after his will was made he had been elected a director of the Mutual Building and Loan Association of Newark—an office he had previously held and resigned—and was considered by his fellow-directors a man of excellent judgment. At about the same time he hired out as foreman at fifteen dollars a week, and after lending his employer a thousand dollars upon security, he so managed as to become the owner of the business. As he was not drunk when he made the will, a majority of the court sustained it.

Clifton v. Clifton, 47 N. J. Eq. 227.—In 1887 Marian Passage, a New Jersey spinster about 83 years old, and who died within two years afterward, made a will by which she left the whole of her small property to a niece who had lived with her for thirty-five years, and who had been, as the old lady said, a daughter to her. A previous will, made in 1873, had so disposed of the property that a brother of this niece would have shared it equally with her. This brother tried to break the later will by a showing of testamentary incapacity, and to that end put in evidence that at about the time the old lady made it her memory had failed so that she would forget words and could not talk connectedly; that her table manners were revolting; that she played with a doll—which, by the way, he had brought to her; and that she was continually folding little rags and arranging them in her work basket. He also produced a negro servant of hers, whom he had previously employed, who swore that on one occasion Miss Passage asked what certain objects were that she saw from her window, across the street, and on being told they were men asked what men were. On the other hand, the lawyer who drew the will said that before drafting it he had talked with the testator a few minutes in order to satisfy himself as to her mental capacity; that she seemed infirm, but able to talk connectedly upon an important subject, and that she gave her instructions without difficulty or assistance. The Prerogative Court sustained the will, and cited near a score of cases in which the New Jersey courts had held that one might have capacity to make a will even though his memory was imperfect and greatly impaired by age or disease, and he might not be able to recollect the names, the persons or the families of those with whom he had been intimately acquainted, and even though he did childish things at times or talked disjointedly, flying abruptly from one subject to another, or asked idle questions and repeated those which had before been asked and answered.

White v. Starr, 47 N. J. Eq. 244.—In 1889 the Orphans' Court of Camden County, New Jersey, rejected the will of Jesse W. Starr, which had been made five years before when the testator was seventy-five years old. Mr. Starr, who had begun life as a mechanic, had created at Camden one of the largest and most successful iron working establishments in the United States—a concern that cost a million dollars but in the hard times following the panic of 1873 became bankrupt for nearly that amount. An attempt was then made to run these works for the benefit of creditors, but incompetent management by his sons brought the experiment to a disastrous end. He had a son-in-law, however, named White, who did much to relieve his embarrassments, and who furnished him with a home in the last years of his life. The will in question was the last of three, all of which were well adapted to the changing conditions of his fortunes, but the last, after referring to the large advances he had made to his sons, left both of them a nominal sum only, and bestowed the greater part of his remaining property on his daughter, Mrs. White, who had never had any considerable sum of money from him. And her husband was made sole executor. Mr. Starr's sons and another son-in-law contested the will, and made a strong showing of mental disorder. He had once called on a druggist to have an old toothbrush refurnished with bristles; he had made a practice of buying candy, distributing it among children, and offering it to grown folks; he had once got his granddaughter to play the piano, and as she did so he danced in the presence of guests; he would make aimless calls upon his friends, look often at his watch while with them, shake hands with them repeatedly, and reiterate the expression of his pleasure at seeing them; he would ride constantly upon the railroad—so constantly that the president of the company sent him a free pass—but he would restlessly shift his seat while on the train, often stand up as it approached a station, and on one occasion, when he went into a smoking car, he shouted "no smoking, no smoking," several times, used insulting language to one of the smokers, and then, sitting down in front of him he kept mumbling to himself the most insulting of the expressions he had used. It was the commonest of things for him to fail to recognize his acquaintances even after he had been told their names; he had been known to ask where he was when only three blocks from home; once, after waiting a few minutes in a barber shop, he arose, stroking his chin as if he had been shaved, and handed the barber his quarter; when the barber said he hadn't shaved him yet, he put the money in his pocket, mumbled and went out; and he used often to tell this barber about a coat which he had had made in Ireland, and which he called his Irish coat. But on the other hand, there were many gentlemen of the highest standing who certified to his intelligent conversation with them, and some of them had heard reports of his mental failure, and were on the lookout for evidences of it. One of these gentlemen had told Mr. White that the impression was getting abroad that Mr. Starr's mind was affected, and had advised him to have the question laid at rest somehow. White laughed, but afterwards quietly invited two physicians, one of whom kept a private asylum, and the other was consultant on insanity at the Philadelphia Hospital, to visit his father-in-law. The first reported that if he had never heard of Mr. Starr, he would never have thought for a moment that there was anything mentally wrong with him; he might have thought from his way of eating that he was slightly peculiar and eccentric, but nothing more. His opinion was that his mind was sound and his memory good, but that like most old people, he could not stand such a prolonged mental strain as he could have stood earlier in life. The other physician said that the impression he received was that Mr. Starr was somewhat enfeebled physically, probably by age, and that his mind acted slowly, but intelligently; he saw nothing to indicate that he was not competent to make a will. The Prerogative Court concluded that while all the evidence could not be reconciled, that which was free from prejudice and interest showed a case where second childhood was asserting itself, and where there was an occasional and transitory loss of complete control of his mental power, but that the testator was usually in possession of his faculties. "It cannot be said"—remarked the judge—"that such a man does not possess capacity to make a will." The decree of the Orphans' Court accordingly was reversed.

Spratt v. Spratt, 51 N. W. Rep. 627.—A case for which there was as little foundation as one can well imagine, was that of Albert Spratt, of Jackson County, Michigan, an old bachelor farmer who died at seventy-one of pneumonia, leaving an estate worth nearly one hundred and twenty-five thousand dollars, which he willed to a score or so of relatives. If he had died without a will the whole would have gone to two sisters and the children of three brothers, and the sisters would have taken twenty-five thousand dollars each. It was an object of course, to break his will, and the usual process of attacking his testamentary capacity was resorted to. The testimony mainly relied on to accomplish this, was that of the physician who attended him in his last illness, which took place in November, 1886. He had warned Spratt that he would probably not get well, and had asked him if there was any business he wanted to attend to. "Why, yes," said the farmer, "I want to make my will," and that evening he directed a nephew to go next morning for a justice of the peace, whom he knew, to draw it. The will was drawn accordingly next day, or rather was dictated by the testator and written down by the justice. The doctor was present part of the time, and occasionally administered doses of whiskey, quinine and carbonate of ammonia to his patient, who sat up most of the time, leaning his head upon the back of another chair. The doctor was napping, off and on, in an adjoining room, and did not know that a will was being drawn until it was nearly finished. He talked with his patient, of course, and says that most of the time he thought him sane and rational, but flighty some of the time. His flightiness, so far as appears, seems to have consisted in his muttering a good deal to himself—in his wanting to pull on his boots and walk out doors, saying that he thought it would do him good—and especially in his upbraiding the doctor for not giving him a longer warning, and complaining to a neighbor that the doctor had promised him three days' notice. It may be added, by the way, that he did in fact live four days, But the Supreme Court said it was difficult to see anything in this. The doctor farther testified that he was of opinion that the day the will was made the farmer's physical condition in consequence of his disease, was such that he could not have carried any lengthy statement of facts in his mind. But the Supreme Court point out that he did in fact, unaided, dictate consecutively, bequests to many relations, near and remote, and they ask what, under the circumstances, an opinion is worth that he couldn't do what he certainly did do. Of course they sustained the will.

Among other recent cases of this class are two of small importance except as they involve the question of the influence of a dying man's physical condition upon the working of his mind. One of these was an Iowa case in which the will of Michael Duggan (*Duggan vs. McBreen, 43 N. W. Rep. 547*) was contested on the ground that when he made it his mental powers must have been greatly impaired because he was suffering from "a kind of diabetes" which in its last stages tended to produce coma, and was aggravated by fistula and gravel, all of which presumably exhausted his system, especially as he was a man of 67. The Supreme Court said that none of these facts, taken alone, would establish testamentary incapacity, but thought that their weight, when taken together, was a question for a jury. The other was a Minnesota case (*Hammond vs. Dike, 44 N. W. Rep. 61*), in which a codicil executed the evening before his death by a man 75 years old, was disputed because most of the time during his final illness, which lasted less than two days, he was apparently unconscious, and the illness, which began with severe pain, soon brought on great bodily weakness and prostration. Some medical witnesses thought his unconsciousness was coma, caused by uræmic poisoning due to kidney disease. Medical experts differed on the trial as to the measure of consciousness and mental capacity which he may have had or which would be compatible with his physical condition. One of them said it was not unusual in uræmic conditions for patients to arouse to a sound mental condition. A jury sustained the codicil: the Supreme Court sent the case back for additional evidence and declined to express any opinion as to the sufficiency of the showing made.

Another class of capacity cases, on which, it seems to me, the law needs more light, and will be glad to get it from medicine, is that in which the disturbing element is spiritualism. The attitude of the Courts on this question is that while so-called spiritual manifestations are, no doubt, as vice-chancellor Gifford called them, "mischievous nonsense" (*Lyon vs. Home, L. R. 6 Eq., 655*), still it cannot be said that a belief in them is such an insane delusion as will defeat testamentary capacity and invalidate a will. They can as yet be induced to go no further than to say that such a belief may result in the exercise of an "undue influence." The celebrated Judge Gresham had a case before him in 1883, in which John Thompson, aged 74, had left all his property to Mrs. Amanda Hawks, who professed to be a medium, to the exclusion of his only son and heir. (*Thompson v. Hawks, 14 Fed. Rep. 902.*) Thompson had shown signs of aberration, and there was insanity among his relations. He began to talk among his acquaintances about sending messages to his deceased wives, and receiving them from them. When he visited Mrs. Hawks he carried with him a little basket of delicacies for these wives, and told some of the witnesses that she would forward them. He told several people that he had been directed by the spirits of his wives, through Mrs. Hawks, to dispose of his property; they had advised him that it was necessary for his "development" as a medium and had enjoined him to "do well" by Mrs. Hawks. The judge set the will aside and said: "It is useless to discuss here the proposition as to whether or not a spiritualist can make a valid will, or as to whether or not a man who has a monomania on one subject is capable for the general transaction of business which does not concern that subject. The testator was in a weakened state of mind when he came under the influence of a spirit medium. He embraced spiritualism as practiced by the spirit medium, and instead of merely believing in it as an abstract proposition, he became possessed by it and suffered it to dominate his life and override every other consideration. His belief in it was artfully used by the spirit medium—the only one it appeared, whom he ever consulted—to alienate him from his only son and child, and to get his property."

Middleditch v. Williams, 45 N. J. Eq. 726.—On the other hand when William H. Livingstone, who died at Newark in February 1888, and whose family consisted of his little daughter Lillian, seven or eight years old, and his mother-in-law Mrs. Marie C. Williams, he left every thing by his will to the mother-in-law, to go at her death to her son, Wm. P. Williams, but to be held in trust for Lillian until she should marry or reach the age of 25. If she should die before the mother-in-law the latter should take the property; if both died before Wm. P. Williams, he should have it all. No provision at all was made for Lillian's children if she should have any. An effort was made to set aside this will on the ground that Livingstone was incompetent to make it, his mind being occupied by the insane delusion of spiritualism. He had told several persons that the spirit of his wife had told him through a medium in 46th street, New York, to provide for her mother; to give *all* the property to her and do it in such a way that none of his own relatives could get it from her. The judge thought this was hardly evidence of an insane delusion. It seems that when Livingstone first attended a séance he was skeptical, but when the spirits inscribed upon a brooch worn by his mother-in-law, there present, the word "Dickie," which was a pet name of his wife, and made it blaze out in letters bright as diamonds—then he believed. The judge held that he had been convinced by evidence—such as it was—and his delusion was therefore at most an error of judgment.

In this case the judge's illustration of an insane delusion was by supposing one, without evidence of any kind, to imagine something to exist, which did not in fact exist, and which no rational person would, in the absence of evidence believe to exist; and he said the only way in which such irrational belief could be accounted for was that it was the product of mental disorder.

This definition was with great technical skill turned upon those who sought in the Ward will case, here, seventeen years ago, to identify a belief in spiritualism with insane delusion. Captain Eber B. Ward had been one of the most considerable capitalists in the northwest, and was a man of extraordinary force, who carried on successfully a vast complication of diverse business interests. He had died in the street of an apoplectic stroke, and some of his children wished to set aside his will in which he had provided more liberally for his second wife and her children than for them. Ward had dabbled extensively in spiritualism, frequently visited a local medium, had consulted with others, professed to imagine himself advised by a spirit whom he designated as "Cabbage John," and on one occasion, on being told by a medium that the spirit of ex-senator Jacob M. Howard was present, he had offered to shake hands with the ghost and had held some conversation with it. The accomplished Dr. Alonzo B. Palmer was examined as an expert in insanity. The examination was conducted by the late Theodore Romeyn, one of the most astute lawyers at the Detroit bar, but the cross-examination was in the hands of an equally keen lawyer, the late D. Darwin Hughes.

Mr. Romeyn asked the question: "If a man fancies he sees the spirit of a deceased acquaintance standing before him, what should you think was the condition of his mind?"

Here Mr. Hughes interposed: "I object to that," said he, "unless the gentleman complete the hypothesis by the supposition that the spirit is not really there. Otherwise there is no delusion."

The judge said "I think you will have to complete the hypothesis in that way, Mr. Romeyn."

But Mr. Romeyn, instead of completing the hypothesis, argued his right to ask the question, unless it were assumed, as a matter of law, that there were such things as spirits, and he did not think such an assumption could be made.

Mr. Hughes retorted that the field of superstitious belief could not be invaded. He could put any number of witnesses on the stand from the time of the Saviour to this day, to swear that all who believed in the miracles of the Saviour were deluded.

Under the judge's ruling, however, the hypothesis had to be completed as Mr. Hughes had suggested, and the witness naturally answered "Of course that would be a delusion."

"Certainly, it would," said the crafty Mr. Hughes. "*That's giving the witness the definition of a delusion, and then asking him if it is a delusion.*"

The foregoing cases have been for the most part cases in which wills were sustained through thick and thin. By way of instructive contrast may be given an Illinois case (*American Bible Society v. Prince*, *115 Ill., 624*) where what may be called a religious delusion upset a will very speedily. Whether it would have been sustained if the testator had been a spiritualist is another matter. Isaac Foreman died in 1878 at the age of seventy-four owning a hundred thousand dollars worth of property, and leaving a widow and a married daughter, the latter being destitute. His will gave his widow a life-estate in the homestead, his household and kitchen furniture and the farm, stock and tools. Everything else was to be sold and two thousand dollars invested for the daughter and her children; of all the rest two-thirds was to go to the American Bible Society and one-third to the Missionary Society of the Methodist Church. A jury found his will invalid, and the Supreme Court sustained their conclusion, which they said they were bound to do, if there were any evidence to support it. They thought there was such evidence. Foreman was admitted to have business capacity, equal if not superior to that of the average of mankind, owning and constantly increasing, as he did, a large property which needed good judgment, prudence and diligence for its successful management. But he had said in class meeting, while speaking of his children and family, that he was afraid of his life; he had also said he was harassed all the time for money by agents for churches, orphan asylums, colleges and schools and bible and missionary societies; that his mind had been injured by their solicitations, their argument being that his future happiness depended on his liberality; and finally, that he had said he intended to place his money where it would roll up and roll up and roll up until the day of judgment to work for old Isaac Foreman. This daughter had been his favorite child, yet he dressed her poorly, gave her but little education, kept her out of company and worked her as a field hand. The Court say they "find it difficult to believe that an egotism which is so extravagant and distorted that it regards only self in this life, and in the life to come, that wholly disregards and ignores the natural claims of a needy child, known to be worthy and dutiful and loving, and the affections ordinarily implanted in the heart for such a child, can consist with a mind entirely free of disease causing morbid delusion."

These are recent specimens of American jurisprudence bearing upon responsibility in will-making. They involve the effects upon the mind of gross intemperance, senile dementia, disease and approaching dissolution and the illusions of credulity and fanaticism. It will hardly be expected that one who can discuss this subject, if at all, from the standpoint of the law alone, can add any thing to the medical learning upon it. But a lawyer can ask questions which a doctor cannot answer. At least it is to be feared so. If the doctor can and will answer them it will be a distinct gain to both professions.

We would like, then, in the first place, with respect to insane delusions, a definition of them that shall not come out at the same hole it went in at.

We would like to know—and this is a bold query—whether, notwithstanding the law, spiritualism is not in fact an insane delusion; and if so, how potent it may be in the destruction of testamentary capacity.

We would like to know whether dementia, short of absolute idiocy, may amount to such complete and comprehensive unsoundness of mind as conclusively to invalidate a will whatever the character of its provisions. Indeed, can a person so demented have or express any will at all; and may not the will of any person less affected be valid?

We would like to know whether coma implies unsoundness of mind any more than sleep; and if not, how then can coma cut any figure in the invalidation of wills.

And we would like to know whether, in spite of the classical maxim, there is any such necessary connection between a sane mind and a healthy body that any enfeebled, disordered or diseased condition of the latter—short of delirium—implies as matter or fact or law a technically "unsound" condition of the former.

Discussion.

Dr. J. G. Kiernan, of Chicago, Ill., was of the opinion that the paper propounded a good many difficult conundrums. With regard to the question of definition, even the law does not profess to give any definition other than a relative one. In judging, therefore, what is an insane delusion, we must not judge so much by the character of the delusion as the state of the man. For example, a belief in witchcraft at a certain phase of our civilization was fully in consonance with the belief of the majority of the people in a normal state of mind at that period. To believe in witchcraft at a certain period was a normal thing. When educated men trained in the sciences of to-day believe in witchcraft, there is a natural question, is not such a man insane? The vast preponderance of evidence in such a case would be in favor of insanity. To illustrate: I had under my charge in an insane hospital, a man who had been a member of our own profession, who had received an academic education, who had lectured in a college on botany and chemistry. That man was found on one occasion to keep at a distance from a certain patient in the ward. He was asked why he did it. He said the man had bewitched him. Before this, this man, who was a much demented individual, had inflicted on this physician (so he believed) all sorts of tortures by electricity. He was shown that such use of electricity was impossible, whereupon he abandoned the belief so far as electricity was concerned, but to account for his feeling, he adopted the hypothesis of witchcraft. In these cases we must consider the surroundings of the men.

With regard to spiritualism, I think the same test can be applied. It seems to me in the case cited where a man left his money to a medium, and the court held that the man was mentally impaired, that it was right, because he was unable to separate from that medium the phenomena with which he was surrounded, but this was an evidence of undue influence.

With regard to lucid intervals, one case occurred in England, and one or two in the United States, in which an insane woman with restraint of some sort on her limbs, was able to dictate a will, and the court held that the logical character of the will proved a lucid interval.

A person in a state of coma would be incapacitated to make a will; but there are many conditions which resemble coma in which a man can recover perfectly. The question comes up, not what is an insane delusion or an incapacitation of testamentary capacity generally, but what is it in a particular case? Like a number of alienists, I believe there exists a certain class of the insane whose wills should be held valid so long as there is no evidence that the delusion affected the testator's mind. It is a little in the direction of the spirit of the common law. In civil affairs the insane are apt to keep along the ordinary routine of life; in criminal affairs their insanity is most often apparent.

Dr. T. D. Crothers, Hartford, Conn.:—In my experience the question of validity of a will depends upon the soundness and reasonableness of the instrument. I have seen instances where a person in an insane condition made a will which was admitted as a rational instrument without question, because the assignment of the property was correct according to reasonable and rational grounds. To what degree is the instrument rational, reasonable? An instrument is sound when there has been an even disposition of the property. If the property is badly arranged, badly disposed of, the question of soundness of mind comes up, and it may not have been mentioned before during the lifetime of the individual, yet the character of the will will indicate at once a mental defect.

A case was tried recently in New York in which a man's soundness had been previously unquestionable. He conducted his business in a most excellent, sane way. At his death a will was found, disposing of his property in an irrational way, and because of that, the question of soundness was raised and some facts worked up, until it was evident that the man was a lunatic. He had concealed his delusions, and his insanity was unknown.

In another case, in which a will was made by a man who was notoriously insane so far as religious belief was concerned, not a question was raised in court as to the soundness of the instrument and the apparent rationality in which the property was disposed of.

Dr. C. K. Mills, Philadelphia, Pa.:—The questions asked by the gentleman who read the paper (Mr. Chaney) are difficult to answer in a satisfactory way. Dr. Kiernan, in his remarks, struck as nearly as possible the solution with reference to delusional cases, when he said that we must not consider so much the conditions of the delusions as the state of the patient's mind. This is the key to the matter. Here appears a great difficulty with judges and lawyers. To illustrate with reference to the delusions, it is perfectly clear to me, as it is, I have no doubt, to others, that a man may have a delusion relating to certain facts; that he may make statements in support of his delusion, which may be true, and yet the man's mind may be in a delusional state. A man may have the delusion of marital infidelity; he may have the delusion of conspiracy or persecution in any of its forms; his wife may be unfaithful to him, others may conspire to injure him in the way he thinks, yet after all it may be a delusion so far as his mind is concerned. We have to study both the facts and the mental state of the alleged lunatic. A judge once asked me when I made a statement like this, "Do you mean to tell me that a man can have a delusion of marital infidelity, and that man's wife be unfaithful to him at the same time in the way he thinks?" I said "Yes." A man may not have any knowledge of the facts of the case about which he is delusional.

Mr. Chaney asked "whether dementia, short of absolute idiocy, may amount to such complete and comprehensive unsoundness of mind as conclusively to invalidate a will whatever the character of its provisions?" A question of that kind shows the impossibility of a lawyer, who is not posted in medical matters, comprehending the subject. Dementia, of course, is a relative matter, and each case of dementia must be studied for itself. Insanity is relative; dementia is relative. We may have 30 or 50 per cent. of dementia in a case; each case must be studied by itself.

Now as to coma, true coma precludes the possibility of a man having testamentary capacity at that time; yet I have seen in my wards at the Philadelphia Hospital a patient stricken with apoplexy, and practically comatose for all purposes—but the patient rallied every five or ten hours, had lucid intervals, and then sank again into a comatose state. He finally died, and on making a post-mortem examination I found evidences of three stages, or separate attacks, of hæmorrhage in the brain. Such a case once came before the Philadelphia courts.

The points brought out by Dr. Crothers are well taken, yet I do not think the instrument itself should in every case determine the validity of the will. Take the case of a delusional lunatic. We had a man in Philadelphia who was on trial as to his sanity some years ago. The case was a famous one. Seven physicians, men of more or less eminence, testified as to his insanity; but a veterinary surgeon and the jury declared him to be sane. He clearly had delusions, but he had conducted his civil affairs properly, and he was worth perhaps $50,000 or more. He might have made a will perfect in its terms, which would have had on its face every appearance of rationality, yet that will might have been one which was influenced by the delusional state of his mind. Take again senile dementia. An old man or woman—and I have seen a number of such cases—has profound delusions of penury, and turns against sons and daughters who have taken the best of care of him or her. A will perfectly rational to all appearances may be made, and yet it may be the outcome of a delusional mind.

Dr. C. B. Burr, Pontiac, Mich.:—It has seemed to me for many years that the pendulum has swung too far in the direction of latitude in will-making. There are those states which appear in connection with senile dementia, for example, in which perversions of feeling display themselves, but where there is no lack of knowledge as to the terms of a will, or the effect of any of its provisions. A person suffering from impairment of mind of this nature is still considered capable of making a will, although manifestly the perversion of feeling, not amounting to fixed delusions, may have a strong influence in determining the character of the instrument. Such cases as these, as well as others with fixed delusions, should be weighed carefully by the courts in the determination of the question of testamentary capacity. The legal theory as to the reason for the supervision of wills by the courts is, I apprehend, that through this supervision, injustice to dependent relatives may be prevented. If this idea is correct, it seems to me that all these matters should be taken into consideration, for it is in just this class of cases—cases of senile dementia and dementia after paralysis, with strong perversions of feeling, but without delusions, that injustice is most apt to arise. Cases of this nature are most perplexing, alike to the courts, juries, attorneys and experts, and should be thoroughly gone into.

Dr. H. N. Moyer, Chicago, Ill.:—I will attempt to answer Mr. Chaney's questions in a general way. As I understand it, all lawyers would like a foot rule which will measure 12 inches. As a matter of fact, the expert, when he examines these facts, has a foot rule that is 9 inches long in some cases and in others it measures 15 inches; in other words, he examines the facts in relation to their surroundings and by the character of the individual, the time and place. Dr. Kiernan has reflected that idea perfectly.

I wish to mention an instance of a lawyer who is unquestionably insane. He has been tried half a dozen times. He came into my office and asked me to examine him and testify as to his sanity on the following day. This lawyer I have known for years; we grew up together and attended the same school. He called me by my given name, and said, after a conversation extending over nearly an hour, "Do you see anything insane about me?" I replied, "I see no marks of insanity as far as this conversation goes: nevertheless I believe you are insane." He said, "How do you come to that conclusion?" I answered, "Frank, your cigar has gone out at least 20 times in this conversation; you have used about 20 matches to relight it, and they are all strewn about the carpet." This showed a heedlessness amounting to actual disease. In a man who had been brought up in the best of circumstances and amid refined surroundings, it argued an absolute degree of mental aberration. Suppose the case was taken into court, the lawyer might ask, "Doctor, is every man who throws burnt matches on the floor insane?" The foot rule in this case does not measure 12 inches. A variable standard is set up that judges the man by himself, his surroundings, education, time and place. What is an insane act at one time and under certain circumstances may under a different condition be compatible with perfect sanity.

Dr. John Morris, of Baltimore, Maryland, said his observation and experience had been that persons with senile dementia were liable to be unduly influenced by the surroundings in the matter of making wills. He had never seen a man that suffered from senile dementia strong at any time. He, however, consented to witness wills made by such patients, first taking the precaution to ascertain whether the wills were equitable and impartial. Dementia has many phases and degrees and frequently testamentary power is not totally impaired. Memory of all the functions is the most sensibly affected in senile dementia.

Dr. W. J. Herdman, Ann Arbor, Mich.:—In regard to the question under discussion, I wish to say it is an extremely vital matter. Mr. Chaney, who is a lawyer of experience, one who has been the Supreme Court Reporter of Michigan for a number of years, comes before this body, reviewing cases that have actually occurred in his own experience. asking us certain vital questions. We know that the lawyer and the physician on the witness-stand have long been at variance in matters of definition; they have both long desired to get at the truth. The lawyer asks the physician to define certain terms; to explain certain conditions, that in this way certain misunderstandings may be cleared up. Would it not be profitable for us in our line of work to appoint a committee to answer the questions that have been asked?

The Chairman:—Yes, if you will put your remarks in the form of a motion.

Dr. Herdman:—I therefore move, Mr. Chairman, that a committee of three be appointed by the Chair to take the questions propounded by Mr. Chaney under consideration, to report at *the next meeting*.

Seconded and carried.

A HEALTHY BRAIN IS NECESSARY TO A FREE WILL.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY C. G. COMEGYS, M.D.,
OF CINCINNATI, O.

The essential element in the human mind and what distinguishes each self from every other one. and by which our capacity for independent action exists —is the will. In mere bodily organization there is great uniformity, but this marvelous machinery does not constitute self, that directs and moves the organized frame. No more can the organs of sense through which we gain a knowledge of the materials and forces of nature, constitute our personality; nor does the mass of ideas and conceptions, the intuitive consciousness, the perceptions and logical forms, which are so similar in the common mind, involve the element which makes each human being distinct in himself from humanity at large. The essential fact in human consciousness; that which expresses spontaneity, power and ability for independent action is the volitional or regulative faculty. Without this magnificent principle all of the phenomena of mind would be ranked but as so many links in the chain of cause and effect which are exhibited in the universal operations of nature. Men would then be *mere things*—impersonal and irresponsible.

It is the activity, therefore, of this faculty that regulates our mental nature and our independent life. It is, indeed, intuitive; nevertheless, needs to be educated; it must be free in order to govern the lives of men.

The brain is the material basis of the mind, and is subject to all the physiological and pathological laws of other viscera; it has a great range of capacity as an organ; it needs a simple supply of blood for mere nutritive changes, but a much greater and momentary one when supporting *mental actions*. The vital chemistry must no where have freer play than here. It must rest, too; it becomes fatigued by ordinary and unexciting uses; but inordinately employed for long periods the balance of nutrition becomes disturbed; it wears excessively, its organic tone is lowered, and it loses ability for normal manifestations of mind.

The mind is builded by the gradual formation of ideas, the materials of which are derived through the senses, but are shaped into concepts by an innate faculty. The accumulation and retention of these form the raw materials of our intelligence. These factors, great or small, are stored away in associated forms and constitute our judgments of things *more* or less compound and complex. They are inseparably connected with our emotions, and moral and religious *sentiments* which constantly guide us in the discharge of our duties. A *man in* a controlling position should be able to employ all these resources calmly and sagaciously. His capacity for sound judgment and self-possession rests upon his intellectual possessions and the due restraint of his affective nature. Now, this due exercise of mind for our self direction depends upon the integrity of that dominant faculty which we call—the will.

Under this autonomy we possess powers for generalization, or abstraction of our conceptual stores; but if this master faculty be in abeyance, which it is, under conditions of functional or organic lesion of its material basis, our self possession is lost, and we become creatures of mere impulse—may I not say mere automata! The fine powers for analysis or synthesis are shattered, and what remains of mind is a mere exhibition of associations of ideas. The treasures of knowledge are still held, but no longer coherent and under discipline; like a ship under sail without a rudder, backing and filling, a mere drift; or an army without an adequate commander to direct its march or its battles.

This supreme mental force is no "transcendental entity" to be considered *apart from physical existence*, but may be said to be the correlative of the totality of the organic power of the brain. It is, therefore, only a well rested, well nourished and properly exercised brain that can display the freedom of this magnificent endowment of man. Thus it is, that psychology comes under the autonomy of the medical profession. The progress of physiology and pathology have shed immense light on the relations of the brain and the mind. From a remote period the brain has been known as the center of sensation and motion, but only within a few years have they been definitely located in the cerebral mass; and the specialization of areas in relation to their functions is now so well known, and their coördination for the *execution of instinctive and acquired movements*, that we can put our fingers on the exact regions where exists our capacity to think—the area where sensations are shaped into concepts—where ideas are symbolized in language—where memory holds its seat, and the imagination displays its marvellous powers. All the apparatus of our organic life—the organs of respiration, digestion, circulation, excretion and the great neuro-muscular systems, are merely to sustain and develop a definite region of the periphery of the brain, which can be covered by two hands. This is the realm of consciousness—the plane where spirit greets matter and the healthy life which enables a man to say "I know that I know; I feel that I feel; I think that I think;" it is where the human consciousness equipoises the cosmos. Gravitation is instantaneous in its action; consciousness just as rapidly reaches from the center to the circumference of the universe. Who but the physician has the right to supervise this dread region? Closer than the minister of religion, or the ties of blood, he stands the guardian of its illimitable faculties.

Through physiological research psychology has been lifted above the misty, subtle reasoning of the schoolmen into the light of a new day, and is now comprehended as never before. Metaphysics is no longer a jugglery with words and phrases, but is a *function of consciousness* only existing in a healthy brain; it is the *purest* and highest expression of reason, and cannot be displayed when the brain is functionally or organically unsound; it is a psychological systemization of ideas under the regulative faculty—the will—whereby the intuitional phenomena of thought, and the phenomena derived through the senses from external objects—the ideal and the real—the subjective and the objective—are brought into accord, and the consciousness is freed from baleful illusions, hallucinations and delusions. The imperfect state of consciousness in unsound sleep wherein ideas flow freely, regulated only by the law of association, represents an abeyance of the metaphysical faculty. We are led everywhere by the most absurd, grotesque, or fearful ideation without self-control, until further aroused and the spell is broken. There is no metaphysics in dreams.

The due development and direction of brain life, appertains to hygiene and sanitation. The manner of living, therefore, is of the first importance in order to obtain a healthy brain structure. This relates to air, clothing, food, exercise, employment and sleep. Whatever impairs any one of the great organs will, sooner or later, involve the health of the brain.

While the mental power of a race, or of an individual may be lowered to almost a brute state by exposure in inclement seasons, with inadequate clothing, poor food and bad air; on the other hand softness and needless indulgence, frivolity and luxury, lead to effeminacy. Children should be the offspring of healthy parents and be reared on plain substantial food; and, at the same time, the means of abundant and attractive exercise in the open air should be afforded. Instead of sleeping in heated rooms, luxuriously furnished, they should be without fire except in quite cold seasons, and be free from the decorative garniture of our fashionable people; and the hours of sleep should be ample and regular. Physical hardihood will thus be secured and the material basis of a strong mental and moral character be laid down. But the future character of an individual thus endowed with physical health will depend largely on ancestral conditions and the moral, religious and intellectual training which he receives.

We should always make a distinction between *impulse* and *will*. From the invariable manner of accumulation and association of the mass of ideas which constitute intelligence; over and above the immense number of actions that are normally automatic, there are constantly seen those which are the result of mere impulse, therefore involuntary, and not in any strict sense those which are willed or voluntary.

The impulsive and involuntary ones, in the sense I mean, are those which a sound will should be able to restrain. These impulsive actions, morally speaking, are the dangerous ones in our lives; for though they are so often good and commendable; yet they are constantly liable to be wrong. To restrain these and subrogate them completely to the will should be an aim in education.

The will can originate nothing, it can only take of the ideas which we possess and coördinate and direct them. It is by the will, I repeat, that we analyze and compound our notions, calmly reflect on our mental stores, and make such selection of them, and give such a direction to our thoughts as subserve our purposes in investigation, reasoning, and a final judgment on any given occasion. By our will we direct our way; by our impulses we are led, and too often driven. By early, constant, well directed training, more especially by inculcating habits of strict obedience to authority, whether relating to superiors, to sound precept, and the restraint of emotional impulses, the supremacy of will may be firmly established: and this is made more certain by the fact that the material basis of the mental and moral nature grows to conditions under which it is continually exercised.

The domination of the will is indispensable in concentrated thought: the control of the sensibilities is equally important; for unless feeling, appetite, desire are under government, our character is too unstable for the fulfillment of our responsibilities in society. Reason, reflection and judgment are all frequently overcome by the suggestions of appetite and passion; unless a strong rein is held by the will over the affective faculties.

There are mild and apparently innocent mental indulgences which exert, nevertheless, bad influences upon character. I refer to reverie—day dreaming—a species of mental intoxication, in which the mind is abandoned to drifting under the influence of mere association of ideas. There is no will in exercise; the imagination governs thought, and this sort of sublimated egotism, gives so much pleasurable cerebral excitement that, unless resisted, establishes at length a species of mental constitution akin to insanity. Every physician meets with cases where this pernicious mental habit involves, more or less, the reasonable actions in the individual. Habitual indulgence in mild reverie has a tendency to dementia; "day-dreaming" (castle building) attended with excitement as it often is, especially when related to great expectations, tends to a "delirium of greatness."

More attention should be given to this subject. It is to be hoped that physicians will study carefully its evil tendencies. Teachers, too, must awake to a consideration of its deleterious effects upon a pupil's mind. It is bad enough to be subject to this dream life when we are in unsound sleep; but every one should be warned, when awake, to keep the will, and not the imagination, at the helm for the voyage of the day.

To "keep cool" under exciting circumstances, to keep silence under great provocation, form great factors in magnanimous men; all of which depend so much upon the culture of the will.

More important still, is the use of the will, and not the memory, merely, in the exercises of schools and colleges. It is undeniable that the method of teaching in American schools has been grounded too largely on exertions of the memory in acquiring tasks. Lessons have been memorized, and not acquired by effort of the understanding; hence, they are not well retained and furnish a poor basis for wide intellectual culture. A lesson cannot be understood by an act of the memory. Severe efforts at memorizing in order to make a good recitation (cramming) fatigue the brain and lower the power of the intellectual faculties. It is not a process of ideation. The most eminent authorities in psychology agree that all sensations contributing to ideation must be symbolized or objectified *by the mind itself* in order to be comprehended; that we cannot think in determinate forms without the formation of mental images (the representative faculty) to *guide* our thoughts; and without these no concept can be formed, no reasoning is possible. Herein lies the true line of demarcation between a memorized and an understood lesson; the former is gained by mere repetition of words and phrases and does not make a lasting impression; the latter is an analysis by the will; the intellect frames its own concepts in regard to it, and it remains; it is understood, not in the phraseology of the text book, but as a real part of the mind's work. The master who knows thus how to draw out the powers of the mind in the acquisition of knowledge is the great teacher, and is always gratefully remembered; for he has revealed to his pupil that his life's success depends upon persistence in plans that are well conceived, and purpose in all his aims.

This process of culture by the will gives largeness and stability to the intellect; all the subsidiary faculties concur to aid the great aims of the will. The *memoriter* method, on the contrary, weakens the will and, I repeat, lowers the powers of the mind.

Nothing seems to be so much neglected as the higher culture of the will in the minds of youth.

The notion that to develop a strong, healthy mental life by daily exercise in purposive thinking is not a new one in medicine. The famous Dr. Rush gave lectures, in 1802, to college classes at Princeton on physiology, and he insisted that a student should exercise his mind every day in close thought in order to give expansion and stability to its capacity: that as muscular organs are developed by activity, the brain follows the same law, and may be increased up to full limits as the material basis of the higher forms of mental activity.

What is likely to damage the brain so that the will becomes impaired, if not lost?

I have mentioned the affective faculties, the basis of which are the feelings of pleasure and pain, that accompany and play upon purely intellectual actions and which regulate greatly their scope. It is the inordinate exercise of sensibility that is especially destructive of voluntary function. Success exalts good feeling which, if unrestrained, goes on to ecstacy; while disappointment, if unrestrained, tends to melancholia; thus the exciting and depressing passions unduly developed reduce the powers of the brain by wear and tear more especially in regard to the exercise of will; and the individual becomes exposed to the dominion of his passions. To grasp, to conquer, to excel, to accumulate, to control, to "corner", to envy, to hate, to revenge, to lust, to destroy; any or all of the terrible elements of evil that dwell in the soul may arise and govern the life of a man. His reason becomes subrogated to his passions which seem like *ferocious beasts*, in ambuscade, ready to leap upon and destroy it.

I have only mentioned incidentally the term insanity thus far, though I have said enough to exhibit this general definition of it; that from its mildest to its grossest forms, it is a loss of voluntary power, of freedom of the will, and I again assert that the brain and its functions are under the care of the medical profession. We are able to declare that men in the management of great trusts who engage in speculation in commercial material, or those in exalted positions in the state who exhibit a vaulting ambition, become dangerous to those trusts and to society, more especially if they practice excessive indulgence in mere animal appetites or live what is called a fast life.

The stupendous ventures made in stocks and produce in the great centers of commerce are often manifestations of insanity, superinduced by the methods I have indicated. Every faculty of the mind, intellectual and emotional, is urged without restraint to the utmost limit; the operator ceases to be reasonable: he becomes impulsive, therefore uncertain and dangerous to his environment. It is impossible to truly estimate the sinister influence which a rare stroke of fortune in speculative trading will work on the mental and moral constitution of the operator. The coolest men begin usually with reasonable circumspection, but, while winning, a species of intoxication gradually creeps upon them; they sleep less soundly and, quite commonly, drink intemperately and acquire a notion of their extraordinary judgment on ventures; they think that they have discovered the law of success. At length the tide turns, they begin to lose. Then they make bolder strokes for recovery, and failing, chagrin depresses them, and excitement gives them no rest, wear and tear is rapid, the brain loses tone, self-restraint disappears, madness seizes them, and they hurl everything within their grasp, not excepting the property of others, trust funds, bank capital—all are thrown into the wild vortex of hazard and swallowed up in ruin. These things are constantly occurring. Is it depravity or insanity?

In fever, *mania a potu*, moral shocks and narcotic appetite we see, every day, reason dethroned; and, alas, under powerful excitement the vilest passions often surmount and reign over the grandest minds. The inordinate indulgence of our affective nature enervates the brain, and the disturbance of nervous force impairs the tone of the circulation in the penetralia of the organ; its pressure, rapidity and volume are disturbed, the metabolism is changed and its functional volitional capacity becomes abnormal.

We warn men, but they will not heed us. They mock at our solicitude and boast of their capacious, unlimited powers; but, sooner or later, the wear and tear shows itself; the ship steers wildly because the pilot is losing his keen eye and his firm grasp of the helm. We turn to the institutions of learning and say to the teachers, "Your overstimulation and exaction, by a multitude of tasks, will impair the usefulness of your pupils; your prize scholars shall not shine in the contests of life so well as many of their duller fellows." We warn the people against luxuriance, indolence and a constant use of stimulants, and excess of any passion or appétite; for, while many organs of mere animal function suffer, the great brain itself becomes undermined. It is appalling to contemplate the social destruction about us on account of the passions of avarice, peculation and lust which have so greatly defiled public virtue.

I turn now to a brief consideration of the insane manifestations that we so commonly encounter in our medical practice. I refer to such affections as melancholia, monomania, hypochondria, neurasthenia, hysteria, alcoholism, morphinism and hypnotism. All of these may be ranged under the insane category. They originate mostly in hereditary types of constitution, in errors of education, want of parental training and abuse of the organism by excesses of any kind. It is unnecessary on this occasion to display the clinical phenomena in these diseases, and their differentiation; they are so well known. The reciprocal relations, in a pathological point of view, of mind and body are very marked. The physical conditions are often of a serious character, and the functions of organic life become gravely involved. In the treatment of these diseases the highest capacity of a physician is required. It is not only the sufferer who appeals to our experience; but the family upon whom these calamities have fallen.

What can we do for hard drinkers and drunkards—those dreadful creatures, often full of violence, and whose homes are made terrible? They are diseased constitutionally, and have become mentally incompetent. They generally freely acknowledge their vices and will promise, and even take the most solemn oath, to cease their potations; but they find that their will power is too weak to resist the diabolical thirst; the cry of the nerves for the missing stimulant is often expressed by cruel neuralgias that overwhelm their purpose of reform. What can save them? We reply, isolation and systematic employment for a period sufficiently long to allow organic and voluntary life to reassert itself. Let it be written over the portals of the place of detention: sobriety, liberty: inebriety, isolation, labor. One to two years should be required for their detention, and when dismissed, it should be on a ticket-of-leave only.

Precisely this method should be employed for the treatment of morphinism or any other narcotic habit; and it should clearly be inculcated that though they seem to be cured of the appetite, abuses have left such a vicious constitution that the smallest amount of any of these toxics taken, will arouse the old appetites and bring them under bondage again. Total abstinence is their only safety.

Modifications of this method will apply in the treatment of melancholia, monomania, hysteria, neurasthenia and hypnotism. While such patients should not be required to employ themselves in any exhausting physical labor; yet, with as little delay as possible, they should do something that will develop voluntary activity. As Dr. Weir Mitchell has shown us, complete isolation in special hospitals, under trained nurses, is indispensable; they must be cut off absolutely from seeing every one but the physician and his nurses. No correspondence should be allowed, or flowers or tokens of affection from parents or friends. The nurses must not be sympathetic nor overattentive, nor comply with all appeals for service. The subject must be taught self-help as far as possible, and be discouraged from complaining of aches and pains; nor dwell upon past sufferings. It will not hurt the patient to become indignant, or to weep; indeed, the nurse should assure her that these outbursts are indications that her disease is abating; but the nurse should never show resentment by word or deed, but simply reply that she is carrying out the doctor's instructions in all that she is doing. These poor sufferers at first are continually wanting something done for them—a bag of hot water, or a mustard paper, or a poultice, or to smell camphor, or bathing of the face or hands with cologne. All these requests must be refused. After a time the worst cases of them will begin to grow calm and obedient, their impulsive actions will diminish, and self-control at length emerge. Then a course of treatment should be entered upon that will increase the power of voluntary activity. Massage and electricity should have been employed from the first; but there is a danger in an excessive use of both of these agencies; for if too constantly used, a habit will become established that will impair self-control. Sewing, knitting, embroidery, drawing or painting, should make up a portion of each day's duties. I have often directed a review of certain portions of the arithmetic, or geometry, and in some cases the writing of English into French or German, following the vocabularies and models in Ollendorf's grammars. All of these exercises require a positive exertion of the will, and they grow into self-possession in this way very satisfactorily. For forty years I have practiced a method of developing self-control by simply exacting a solemn promise from such patients, that they would not speak of their ailments to any one but myself. Indeed, with office clients who are suffering with milder hysteria, hypochondria and neurasthenia, it works well. I have had a large observation in this line of practice, and will say that I think that the ingenuity exercised in their successful management is greater than in most other affections. The so-called Christian science or faith cure people, get their success in this way. My limits forbid my further enlargement of this subject.

What I have desired to show is the differentiation of will and impulse—that the essential element in the perversion of intellection and emotion in all insane diseases is the abeyance of the will; that we should not say of these patients, that they have an obstinate will, but rather that their ideas are unregulated and unrestrained, and cannot be otherwise without a restoration to health of the area of the brain where consciousness exists; that to search successfully through all the hidden paths of the misty labyrinth of mental alienation, we must take as a guiding thread, that functional ill-health superinduces a lowering of consciousness and an invalidation of voluntary power. By all approved remedies we must seek to improve the general health of the body and a rational volition.

In a brief conversation I had with Prof. Charcot last summer (he was my clinical teacher many years ago), I ventured to say that I thought in the studies of the startling phenomena of hysteria and hypnotism, sufficient account of the aberration of the will had not been set forth. He replied that there were in these cases manifestations of strong will. But, I continued, the researches under your direction by Gilles de la Tourette and Cathlineau had shown that these cases were in bad health; therefore these mental phenomena were merely impulsive; that the influences of suggestion in hypnotic cases were the guiding sensations.

In a final remark let me say that this subject is largely related to cases in medical jurisprudence which involve a differentiation of insanity and depravity; also in various questions of moral irregularities, and the difference between automatic and purposive action. This whole question is too large to compress satisfactorily into a paper of thirty minutes length.

Discussion.

Dr. C. H. Hughes, St. Louis, Mo.:—I would qualify the
statement of the paper that hypnotism is an absence, per-
version or impairment of the will to the extent, viz.: that it
is a perversion of the will dependent upon a *hypnotic* or
sleepy state. Some of you may know that I offered a sub-
stitute term some years ago for hypnotism, which was som-
navolism. This term I consider more expressive of the
hypnotized state than hypnotism. Hypnotism signifies sci-
entifically nothing except a condition of sleep, which
it is not exclusively. Hypnotism is a scientific misnomer
because he who is in a sleepy condition is simply in
generally a drowsy condition; whereas something in the
individual becomes passive in the hypnotic state. The
individual becomes abeyant to the suggestions of another.
Abeyance to suggestion is the phenomenon of hypnotism.

It is somnavolism. It is the normal will of the individual made obedient to another through the sleeping process. It is a partial absence of the individual's normal will through the sleep process (*somnus a volo*). It is not a psychical process induced by the influence of the operator as was taught by Mesmer and his followers, and whose term *mesmerism* was equally as good as the substitute term of *hypnotism*, both signifying a similar mental condition. I called attention to the term proposed for this condition some years ago. in the *Alienist and Neurologist*.

Dr. Comegys has given us an excellent dissertation on mental hygiene for the public. Such a paper ought to appear in the higher class magazines that the people may know the true relationship between the psychical and the physical in their mental processes. I presume every one in this Association is in accord with the sentiments of the paper, and no one is better qualified than Dr. Comegys to discuss the subject.

Dr. C. G. Comegys, Cincinnati, Ohio:—I am glad to hear such kind expressions from my friend, Dr. Hughes, on this very important subject. I do not think we can over-estimate its importance. I have a feeling, which I believe is true, that this profession of ours is the greatest in this or any other Nation. Instead of playing a subsidiary part, we have more right than most men to stand by and dictate in regard to matters pertaining to the welfare of the public, and we should exercise all the influence we can to get recognition in the State for our profession.

In looking over the proceedings of the International Congress of Hygiene and Demography, which met in London last year, and noticing the welcome extended there to the French, German, Italian and Austrian scientists, I regretted to note that there were only two or three men to represent this great Republic of sixty-four millions of people. There was a distinguished gentleman from Minnesota and Dr. Vaughan, an eminent man, from the University of Michigan, but they did not officially represent our country; they were not asked to say anything.

Sir Joseph Fayrer, President of the Congress, and one of the most distinguished men in Great Britain, declared that though they had accomplished much work in England through the Local Board, a sort of national medical board in London, where Simon, Burdon-Sanderson and Klein have labored successfully, there is no telling what could have been accomplished if they had had a medical minister of the State.

NOTE ON THE HYSTERICAL CONCOMITANTS OF ORGANIC NERVOUS DISEASE.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY C. H. HUGHES, M.D.,
OF ST. LOUIS, MO.

The conclusion, "Some hysteria, *ergo* all hysteria," is a clinical conclusion which has proven in numberless instances fatal to correct diagnosis and to the welfare of many patients.

This neurosis may be latent as any other inherent tendency to neuropathic instability may be and often is, until some psychical or pathological cause calls it into morbid activity. While hysteria is essentially an imitative and functional disturbance of the psychomotor, sensory and ganglionic centers, it is no more unreasonable to expect its development in conjunction with grave organic lesions of the cord or brain, than to anticipate pain or spasm from profound central disease or even from multiple neuritis of the motor nerves extending to the cord centers or involving contiguous peripheral sensory nerve fibers.

The time has fully come, in the progress of neural pathology and clinical neurology, to recognize this fact and realize its true significance in our clinical judgments, for without such proper recognition we may be too often led astray in diagnosis and prognosis for our patient's welfare or our professional reputations before a scrutinizing and discerning public.

Hysterical patients are prone to develop peculiar inherent neuropathic characteristics of their organism under physical as well as psychical stress, and this physical strain may be a real central or peripheral structural disease.

It has been quite a number of years since the writer first began to think in this way, and ample observation has confirmed the correctness of his earlier judgments, though not until after some serious clinical errors had been recognized after the issue had been determined post-mortem.

So far back as 1867-8 and 9, 80 and 81, several of my autopsies at the Fulton Asylum for the Insane on patients who had died of organic diseases of the brain and other organs, some of whom had been pronounced *only hysterical in the communities* from which they came, and one or two of whom had hysterical seizures while they lived in the institution, set the author to thinking on this subject, and led to a final revision of his *previously entertained* view that hysteria was always a functional nervous disease invariably only associated with functional nerve trouble.

It was not long after leaving the asylum that a very markedly instructive case, because of its tragic ending, fell under our observation.

The case was that of a lady past the menopause, and mother of several grown children, who suffered from disseminated sclerosis, with characteristic pupillary changes, intention tremors and insomnia, and with numerous hysterical symptoms and frequent paroxysms.

Her case had been pronounced by old and experienced physicians to be hysteria and hypochondria (which latter, by the way, is another much misapplied term because it, too, does really, though less frequently, co-exist with grave physical lesion).

A multiple neuritis co-existed in this case and she had exacerbations of neuralgic pains.

This woman really suffered physical agony, but the verdict of her family physician and a consultant from the city, that the case was hysteria, lost her the sympathy of her husband and children which she deserved and craved, and in her despair, chagrin and grief, she took her life.

Thos. Buzzard, in his presidential address before the London Neurological Society in January, 1890, has caught a glimpse of our subject in a little different light. The essay as since published by Churchhill, of London, is entitled, "The Simulation of Hysteria by Organic Disease of the Nervous System." In this little brochure the fact has not escaped this able clinician's observation that hysterical symptoms may co-exist, even with so grave an organic disease as disseminated sclerosis, but he thinks it is the sclerosis which causes symptoms which simulate hysteria, whereas we think the hysteria is real, and the sclerosis is the *casus mali* that brings into prominent morbid activity the latent functional neurosis.

He even makes certain hysterical symptoms a necessary part of the organic disease he is discussing. We quote—"It appears to me reasonable to conclude that many symptoms which have come to be considered characteristic of hysteria will, if examined in the light of improved knowledge and experience, be relegated to disseminated sclerosis. The figure of hysteria shrinks in proportion as the various forms of organic disease acquire greater solidity and sharper definition."

But we have not always found this to be strictly true, except as the fatal ending of disease approaches, and we have in view one instance in a male which though death is impending from probable syphilitic arteritis and gummata with cerebral congestion the patient has numerous crying spells with spitting out of food and medicine, and violent tendencies at times followed by laughter and tranquility. The congestion of brain is evidently a malarial complication with cold stage, fever and sweating, reaction and intervening better days.

Buzzard's book is good reading *a propos* of our subject and bearing in mind the difference of view, viz., that in our opinion the hysterical symptoms are always brought to the surface in persons who have this neuropathic diathesis and in no others by the irritation of an organic disease, while Buzzard regards the hysterical symptoms as necessary signs of the organic disease. He has found hysterical symptoms in Friedreich's ataxia and secondary cancer. We have one of the latter cases now under treatment or rather as a sequence to a second removal, the patient having, also, been really insane with delusions of electricity, etc., and periodicity of exacerbation as of malarial poisoning.

He details a case of hysterical paraplegia dependent on atrophy of the ilio-psoas muscle, and a number of cases of disseminated sclerosis mistakenly diagnosed as hysterical, one of them in a male patient and one case like our own terminating fatally.

We remember to have seen one case of posterior sclerosis in a female, in which the pharyngo-laryngeal crises were so distinctly intermittent and the sensation of globus was so like that of hysteria that we were often uncertain as to whether the patient did not really have the true globus hystericus from the irritation of the changes in the pons and medulla and the reflected gastric crisis. She had other hysterical symptoms, and had in her earlier life been a victim of this neurosis spasmodica. She died, however, in a cardio-laryngeal crisis.

In the recent publication of the Salpetriere Cliniques,[1] Volume, 1, 1872, Charcot relates a case of Morvan's disease complicated with hysteria and several cases of hysterical tremblings having associated variations of intention tremor and vibratory tremor. These were probably, as they were apparently, associated with sclerosis.

Five days ago a lady, now dead of cerebral congestion, came to my office at the instance of Dr. Mayger of this city, with general hysterical trembling. Her history had been one of mental shock and over nerve strain.

I have seen a case of abscess of the cerebrum following a cerebritis preceded by hysterical symptoms till near the close, and a school teacher of 22 years overworked and anxious about her ability to continue teaching developed hysteria along with general neurasthenia and malarial poisoning, the latter ending in cerebral congestion, temporary insanity and death, the hysterical symptoms disappearing as the gravity of the cerebral disease increased.

Hysteria sometimes displays itself in connectio with epilepsia mitior as well as in the grave form o hystero-epilepsia. It has been developed in my observation after diphtheria, scarlatina and rheumatism. In these instances I have always found a famil history of this or other form of spasmodic neurosis. It is not uncommon in ordinary chorea, especially later in life after an earlier chorea; one of m present cases of chorea major shows hysteria markedly. But these are both ordinary functional nervou diseases.

I think I have seen it in one instance brought ou during the convalescence from hemiplegia as chorea sometimes appears.

With these clinical facts before us, are we not justified in extending our search for hitherto unsuspected organic disease of the nervous system as causes of hysterical symptoms, as well as in looking to the womb for the fountain source of this symptomatic neurosis and in relegating to the back-ground the prevailing clinical dictum that, "Where hysterical symptoms present, the trouble is only a functional one of the nervous system?

It is undoubtedly true, as Buzzard has clearly shown that hysterical symptoms develop *de novo* only in part and as part of the expression of organic nervous disease. I have seen such cases—cases where the mind was for quite awhile in doubt as to the real nature of the disease—whether organic or functional. As one may see paralysis appear and find the cincture feeling present and the knee jerks absent in hysteria sometimes, so may he see symptoms of hysteria in real organic disease. I may note here a case of salam tremor or rhythmical contractions of the sterno-mastoids, long suspected by myself to have been hysterical, which proved to have been caused by cervical pachymeningitis of which the patient subsequently died.

As this is but a note of clinical warning we trust this word may prove sufficient to the wise clinician and with a brief quotation slightly qualified to compass our own view we close this paper as Buzzard has introduced his able address, our object being. "To draw attention to the frequency with which symptoms liable to be looked upon as (solely) hysterical are found to be really due to structural changes in the nervous system" as the exciting if not solely causative factor.

Discussion.

Dr. J. G. Kiernan, Chicago, Ill.:—It seems to me in addition to the point raised by Dr. Hughes, that there is another point that it will be well for us to consider. There is a very popular notion that hysteria is a purely imaginary condition. But there is a growing tendency to look on hysteria as an expression in many instances of congenital defect the result of a teratological condition in a woman; so far as clinical phenomena are concerned, due to instability secondary to *that teratological condition. Of course, it may be acquired,* and the natural corollary would be that it can be simulated by almost any of the organic neuroses.

A little over nineteen years ago I reported a couple of autopsies in which secondary hysterical paraplegias, spinal changes, were found which were considered secondary hysteria*; in other words, it was an ascending condition.* *is fair to assume that it may have* originated in such a c dition. The repeated exhaustion of the nerve symptoms by the hysterical condition has resulted in a pathological change in the center with a direct organic condition as a result of that.

Dr. Archibald Church, Chicago, Ill.:—It is with extreme satisfaction that I have heard the paper of Dr. Hughes on this important subject. He has sounded a note of warning, which seems to me has been long needed in the general profession. We know there is a general tendency on the part of the average medical man just as soon as he encounters well marked symptoms of hysteria to attribute every manifestation of disease in that particular individual to hysteria without further investigation.

---

[1] Clinique des Maladies du Systeme Nerveux, M. le Professeur Charcot, pendant les annees, 1889-90 et 1890-91, sous la direction de Georges Guinon Chef de Clinique. Publications du Progres Medical.

"Relation d'un cas type de maladie de Morvan complique d'hysterie. Superposition des anesthesies hysteriques et de Morvan chez le meme individu".

I have read the little book of Buzzard with a great deal of interest, and I feel with Dr. Hughes that he has gone too far n attributing to hysteria the importance he has in relation o organic nervous disease. On the other hand, I feel that Dr. Hughes has gone a little too far in attributing the position he has assigned to hysteria in his article. The main point to remember is that hysteria may be followed by organic nervous disease; and that a person with organic nervous disease is not therefore exempt from hysteria, but rather is the more likely to be subject to it.

I am glad Dr. Kiernan referred to some of these French cases in which organic changes have been found and attributed to hysteria. For instance, hysterical contraction has been noted and assigned to hysteria, and after many years changes were found in the cord and attributed to hysteria.

If these cases were more thoroughly studied, I think we should find organic disease of an ascending character upon which hysteria had been engrafted or which had occurred in hysterical individuals.

I trust the paper of Dr. Hughes will be widely read, as it will point out to the practitioner that every hysterical case demands as careful attention to possible organic changes as if hysteria were not present or suspected.

Dr. James Taylor, London, Eng.:—I was very much instructed and interested in the short paper of Dr. Hughes, from the fact perhaps that I knew Dr. Buzzard was collecting material for his book, which he afterwards utilized in a paper read before the London Neurological Society.

I have watched a good many cases similar to those reported by Dr. Buzzard, and had an opportunity of examining some of them post-mortem. As I understood him, ascending sclerosis was the disease he considered chiefly in reference to hysterical manifestations, with the other manifestations of organic disease; that in disseminated sclerosis there are a great many hysterical symptoms, and these may serve to us as danger signals, not by any means to be neglected or passed over; that in such profound disturbance of the nervous system as occurs in a disease like ascending sclerosis, any underlying instability of the nervous system, which is usually manifested in so-called hysterical phenomena, is liable to be present. In that sense the hysterical symptoms are manifestations of organic disease. Of course, every disease, strictly considered, is functional in its manifestations. Although we know there is now a line of organic change in the nervous system, still the symptoms of disseminated sclerosis are manifestations of disturbed function. I think in order to be on the right road in the whole matter, we shall have to get a definition, which I admit is a very difficult thing to do, of hysteria on the one hand, and organic disease on the other. Do we know that there is such a disease as hysteria at all; that is to say, a purely functional disturbance of the nervous system without some underlying organic change? The change may not be manifest to our methods. There may be chemical changes. Of course, we know that a certain class of symptoms are classed under the convenient term of hysteria, but we have no accurate definition. And while I say at Queen's Square our attention has been directed to the so-called hysterical manifestations of disseminated sclerosis, I do not think that the hysterical manifestations are by any means confined to that.

I think Dr. Hughes is to be congratulated on the extremely able and vigorous way in which he has brought the subject before the Section. Through the kindness of your Chairman I am here with you, and I am extremely gratified to have been here this afternoon to listen to the able paper which Dr. Hughes has read. (Applause.)

Dr. L. Bremer, St. Louis, Mo.:—I wish to state that the paper which Dr. Hughes has read is in perfect harmony with the modern tendency of neurology—that is to say, the "weeding out" process of the neuroses. When we say that such and such a disease is a neurosis, as a rule we thereby acknowledge that we are ignorant of the true nature of the disease. The trend of medical progress, and of neuropathology in particular, is to find the anatomical substratum of the disease and the pathological factors. This has been done and is still being done in a great many of the manifestations of the nervous system which we comprehend under the name of hysteria, and which has been alluded to by the preceding speaker as a rather vague and meaningless term. I can add my testimony to the observations that have been made as to the utmost difficulty when symptoms obtain in the perplexion of diagnosis, especially in the earlier stages of insular sclerosis and hysteria. I have observed for a number of years cases such as have been reported, and had I not known that these investigations were going on, and observations had been made previous to 1890 that insular sclerosis sometimes does mimic hysteria, my attention would not have been called at so early a date to the possibility of the anatomical lesion which afterwards developed in this case. I wish to call the attention of this body to another fact which perhaps is not quite sufficiently insisted upon, and that is, like epilepsy, hysteria sometimes marks the prodroma or initial stage of infectious diseases. I have observed hysterical attacks in some cases of la grippe during the last two epidemics we have passed through, and one case especially, that occurred at the St. Louis Hospital, had all the phases of grand hysteria as Charcot describes them. Every physician that saw the case and that had a knowledge of the hysterical attacks and had seen them before, pronounced it a case of true grand hysteria, the various phases being well marked. Nobody thought of la grippe at that time. When I made a post-mortem examination I found an influenza pneumonia complicated with basilar meningitis. There was also a cribriform state in the pons. This state had been produced by the pneumococcus of Friedlander, an organism which develops in a culture medium as well as in the blood and in the tissues of the body a gas which is to a great extent hydrogen. The meningitis, together with the cribriform state of the pons (in one place this looked like worm-eaten, and in the cavities the pneumo-bacilli were present in large numbers, together with amyloid corpuscles) must here be looked upon as the causes leading to symptoms resembling hysterical attacks

I have alluded to this case for the purpose of proclaiming myself in harmony with the modern view of eliminating the neuroses, and of showing that in a great many of those cases that were formerly looked upon as purely functional, there is after all a well marked anatomical substratum.

Dr. W. J. Herman, Ann Arbor, Michigan:—One remark made by Dr. Bremer calls to my mind a thought that has not infrequently been suggested to me, as I have had an opportunity to study some of these cases with hysterical manifestations, and also to make post-mortem examinations in some cases of disseminated sclerosis. I have noticed in some cases of disseminated sclerosis in which I have subsequently made an investigation post-mortem, that certain patches of sclerosis were present in the pons. From the frequent association of the hysterical symptoms with those cases in which the lesions were largely in the pons, the thought has been suggested to my mind that possibly it is in this portion of the brain that a disturbance of metabolism or disturbance of circulation, or whatever it may be, must be set up and serve as an anatomical or physiological substratum upon which hysterical manifestations depend. This was further impressed upon my mind by the study of a case in the University hospital some two years ago, which was first thought to be a case of pure hysteria. The physician through whose hands it passed so recorded it, and the emotional manifestations were at first the prominent ones; but at the time the case came into the hospital there was evidence of gross lesion, and the patient was not long in the hospital before death ensued. We found a parasitic growth at the base of the brain of considerable size. It was on the right side of the pons. In this case the hysterical symptoms were at one time very prominent, and the case points in my mind to this portion of the brain as being possibly the region from which hysterical manifestations may arise. Possibly in the early stages the disturbance of circulation, alone occasioned by such lesion might account for the hysterical symptoms.

Dr. J. J. M. Angear, Chicago, Illinois:—A case somewhat germane and perhaps broadening the views that have been entertained came under my observation some years ago. It was a lady patient who had all the manifestations of uterine trouble. She had the peculiar mental condition and a great many of the nervous symptoms common to patients suffering from uterine disease, and upon examination I discovered hyperæmia, an irritable condition of the mucous membrane of the os and cervix uteri. I congratulated myself upon the examination that I had diagnosed the case correctly, treating her in the usual way with sedatives, astringents, etc. She apparently improved for a while with this treatment. but greatly to my surprise in a few weeks she died of apoplexy. Upon post-mortem examination we found the posterior part of the anterior lobe literally "plowed up," as Watson says, showing that my diagnosis was correct only in part, the brain trouble entirely overlooked. There was organic difficulty going on in the brain, and these manifestations which we attributed to the irritable condition of the uterus must not be relied upon too confidently, remembering that an irritable and congested condition of mucous membranes are symptoms of nervous and brain troubles.

Dr. C. H. Hughes, St. Louis, Missouri:—I think Dr. Church did not quite catch my view in regard to Dr. Buzzard. Dr. Buzzard speaks of the development of hysterical symptoms as a part and parcel of certain nervous diseases, especially disseminated sclerosis. He speaks of certain hysterical symptoms as a part of the symptom-grouping of disseminated sclerosis.

The points I make in this paper were not made in the *book written* by Dr. Buzzard. The substance of my paper was prepared by me years ago. I presented a case before the St. Louis Medical Society, in which the symptoms were markedly hysterical and so regarded by other physicians. She finally died with an abscess at the base of the brain. Dr. Buzzard takes no account, in his book, of the latency of hysteria as a neurosis brought into activity by a superimposed *organic nervous disease. From the nature of* disseminated sclerosis, we know very well that its *foci* may be so distributed as to act as sources of irritation, and my view of these cases is that it does act as such in bringing into activity the latent neuropathic tendency, and these symptoms appear in no other patients than the inherently hysterical. They do not appear *de novo* in persons who do not possess the *neurosis spasmodica*. I believe *accumulating* clinical experience will confirm this statement. In all of these cases there will be found I think, a family history of the neuropathic diathesis.

The first case that attracted my attention outside of an asylum was in 1872. My first observed case of disseminated sclerosis with hysterical symptoms was pronounced hysterical only *in* 1872 by a distinguished physician, of St. Louis, and other physicians in the patient's neighborhood. It was sclerosis associated with hysterical manifestations. Hysteria is frequently associated with disseminated sclerosis. I believe it is a safe thing to suspect the beginning of sclerosis in patients with hysterical symptoms who also have lowered reflexes or impairment of them and rhythmical movement or *intention tremor.*

DISORDERS OF PANTOMIME OCCURRING AMONG APHASICS, STUDIED PARTICULARLY WITH REFERENCE TO THEIR MEDICO-LEGAL BEARINGS.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June 8, 1892.

BY CHAS. K. MILLS, M.D.,

OF PHILADELPHIA.

[ABSTRACT.]

Pantomime is the representation of ideas by action and movement; it is an intellectual act; according to Hughlings Jackson, it differs from gesticulation as a proposition does from an oath, although the terms gesture and pantomime are frequently used almost interchangeably. Amimia and paramimia are terms which have a corresponding import, as regards pantomime, to aphasia, paraphasia, paralexia, etc., with reference to speech. We may have a jargon of signs and motions, as well as of words and sounds; we may have a sensory or receptive, and a motor or emissive amimia; sensory amimia is in fact a form of apraxia. Pantomimic disorders may be mixed, combined, or associated; we may have all blendings of them just as we have of ordinary speech disturbances. A study of the losses and disorders of pantomime will often be of great assistance to the physician in diagnosis; and in some medico-legal cases decision will largely hinge upon the consideration of the presence, absence, or disturbance of intelligent pantomime. Different and conflicting interpretations are too often given to the *pantomime observed among aphasics*; every case of aphasia should be studied for itself as to pantomime.

In nine cases of aphasia or pseudo-aphasia which were investigated, notable differences and peculiarities in pantomime were presented by the patients.

In one case of brachio-crural monoplegia, almost complete motor aphasia with marked preservation of pantomime were present; in a hemiplegic with convulsions, word-blindness, verbal amnesia, and motor aphasia, there were marked sensori-motor disturbances of pantomime; in a third case, one of right hemiplegia, nearly complete aphasia chiefly of the motor type, the pantomime was varied and uncertain; a fourth case was one of right hemiplegia with marked contractures, complete aphasia of the mixed type with a single recurring utterance, and almost complete amimia; a fifth was a case of right hemiplegia, paralysis of the face, almost total abolition of pantomime, with almost total sensori-motor aphasia, and obstinacy and energetic emotional gesticulation. In a sixth case of marked hemiplegia of gradual development with motor aphasia and anarthria, only a slight degree of loss of pantomime was shown, while case seven, one of right-sided pseudo-bulbar paralysis with anarthria and preservation of writing ability with the left hand, exhibited also full preservation of pantomime. Case eight, was an example of right-sided pseudo-bulbar paralysis and ophthalmoplegia, with anarthria, marked oro-lingual paresis, and full preservation of pantomime, but with considerable mental apathy. The ninth and last case recorded was one of double hemiplegia from successive lesions on the right and the left side of the brain, with absolute abolition of speech and pantomime.

The study of pantomime may become an important diagnostic aid in the fixing sub-cortical lesions, and particularly the position of a sub-cortical lesion with reference to its distance from the cortex. Some of the cases detailed showed that when the lesion was entirely in the straits between the ganglia, the corona radiata escaping, pantomime was either not lost or was soon entirely regained. The speech defect is of the nature of an anarthria or pseudo-bulbar affection, and a diagnostic point is the ability of such patients to throw even into the paralyzed members some volition.

Marked differences in the disorders of pantomime will be found in cases of paralysis and of motor or mixed aphasia which are apparently identical, or at least, very similar in character, which identity or close similarity, however, will often be found to be apparent rather than real; for investigations will show in many cases differences in the degree and character of the motor paralysis, sensory symptoms, and aphasia, which are sufficient to separate the pantomimic disorders into classes.

The medico-legal investigator, even without any appreciation of the nature, extent, and location of the lesions, would recognize important differences between these patients—difference both in speech and pantomime which make it essential for just decisions to carefully study both.

The "yes" and "no" of an aphasic are well known to have very diverse degrees of value. One of these two words may be used to express both assent and dissent; or with its proper meaning; or to express assent when dissent is ment; or simply as an emotional, interjectional, or accidental expression. In like manner, the usual pantomimic method of expressing assent by the forward nod or bowing of the head, and of indicating dissent by shakes or half rotations of the head, or any other movements apparently meaning "yes" or "no," will be found in aphasics to have as many interpretations as the articulated "yes" and "no."

Great care should be taken not to misinterpret the emotional manifestations of an aphasic. The gestures and appearances of the face indicative of displeasure, anger, obstinacy, and irritability, etc., are often strongly suggestive of dissent; while on the other hand those which merely indicate pleasure, amusement, or playfulness, may sometimes be mistaken for assent or accord—facts which the last two cases particularly illustrate.

True amimia is an intellectual disorder just as is true speechlessness. It may be correct to say that emotional language is apparently unaffected in aphasics; but it would not be correct to say that it is entirely unaffected. The expression of the emotions while frequently correct, sometimes energetic, and often violent, is in serious cases of disturbance of intellectual pantomime, not uniform and under control. In many normal individual emotional manifestations may be instantly controlled at any stage, and in accordance with varying inhibitory powers in different individuals, weeping can be turned to laughing; a smile to a frown; the sounds of lamentation to those of rejoicing, by the trained and skilful actor, and in varying degree this power of control is preserved by all normal individuals. In aphasics with serious disturbances of pantomime, the losses shown in the emotional side are seen in meaningless continuations or repetitions, by slow transitions, and undue excitement.

Discussion.

Dr. J. G. Kiernan, Chicago, Ill.:—It is well known that paretic dementia is by no means a bad state to test a good many conditions. There are phenomena which I and a number of others have noticed in the paretic pantomime element. The facial expression may be that of depression, while the general state of the mind is exaltation, and of course *vice versa*. This factor in dealing with pantomime should be taken into consideration. Many aphasics do not retain their mental organization in its entirety. Their intuitions are weak and in the place of one conception inhibiting the other, both come into play, and we have alternation, and at times certain ideas of a directly opposite character are produced from a suggestion. The uncertainty resulting from this condition may produce uncertainty in the pantomime. It has been shown by two or three English writers that in secondary confusional lunatics of the incoherent type, a little attention to certain lines of speech will produce seeming coherence which is a species of reflex intellection, the product of suggestion, and automaton-like.

Dr. Archibald Church, Chicago, Ill.:—Much as aphasia has been studied, I feel that Dr. Mills has introduced us to an entirely new phase of the subject, which we can all follow up with interest and advantage in our own cases. Gesture and pantomime are acquired by a child only after the speech faculty is well developed, and one might expect *a priori* that this complex addition to thought expression would be readily implicated. A case of meningitis recently under observation was followed by complete agraphia and alexia, and when the patient finally got on to his legs, it was found that the power to walk was lost, though station was firm even with closed eyes. There was locomotor amnesia, if I may use such a term, a complete loss of a group of coordinate and continued lower extremity movements corresponding somewhat to the arm difficulty of Dr. Mills' patients. All other movements could be executed with precision and promptness when the patient was in a chair or in bed. In this instance the implication of the medulla as shown by respiratory and cardiac symptoms and sugar in the urine, of the visual area by the alexia and agraphia, leads me to think that the inflammatory process next involved the leg centers in part, by extension upwards along the middle line. The localized pain in the occipital region may also add strength to the supposition. With convalescence the patient learned again to walk, first stepping forward with one foot and bringing up the other, and the aphasia also passed away in the course of a few months.

Personally I desire to express my appreciation of Dr. Mills' instructive paper.

Dr. J. J. M. Angear, Chicago, Ill.:—There is nothing to criticise in the admirable papers of Dr. Mills, but perhaps we might broaden the circle a little in some of these abnormal, or rather we might call them normal, aphasias peculiar to certain individuals. Some individuals seem to be congenitally defective of word sight. Give them a book and ask them to commit a certain thing to memory, they are not able to do so in quiet, but if they can go outdoors or into a room by themselves and commence reading out loud as if reading to an audience, they will soon commit it to memory, showing that they want the sound and not the sight of the words. I knew a gentleman of scholastic attainments that lived to a good old age, who never attempted to read anything in public, unless he had an opportunity of sitting down and apparently studying it. He would then be able to get up and read and no one would ever be the wiser for it. Some never make good readers—forever miscalling words and going back and correcting themselves. Again, by watching closely you will find our good readers can look almost a line ahead in reading, showing that they have very good word sight; while if you inquire of those whom we call poor readers and who have a hesitating style of reading, they simply read word by word as they go along, never looking far enough ahead for the next word, showing that they have very poor word sight. If you give some young men a written examination they make a failure of it; whereas if you make it oral they are successful. You take the same individual and talk with him, and you will find that he is pretty well posted. Very few of our scholars—learned men—become writers. We have other illustrations. We have fine writers of scientific works, of literary works and of fiction—men who cannot get up here and talk five minutes. Words fail them. Give these same men a pen, the choicest words and sublime thoughts come. Their tongues are weak but their pens are mighty. I take it that this is something in the line of aphasia. With reference to pantomime you will notice some individuals in speaking, without any special training in this direction, their gestures give great force to what they say, because there is a meaning in them; in other words, they are appropriate; while others are eternally making gestures that are decidedly inappropriate and awkward, showing that pantomime is very defective in their case.

Dr. William Fuller, Grand Rapids, Mich.:—I wish to say that I have in my possession the cast of a brain in which the first temporal convolution is almost entirely wanting, while the second convolution is very highly developed. This man could remember nothing that was told to him and was generally supposed to be an imbecile. He was a frequent attendant at operas, theatres and all places of entertainment. He went about the city continually humming tunes to himself without using words. He was a man that after hearing a tune once took it in and never forgot it. He very seldom talked to anyone and then only a few words, The occipital lobes in the cast show a very high development as well also does the frontal part of the brain.

Dr. A. D. Rockwell, New York City:—In common with others I have seen various forms of aphasia, but a short time ago a case came under my observation, which although not altogether unknown is certainly of rare occurrence. I allude to what Kusmaul has termed "word blindness," or inability to comprehend visual word symbols. A gentleman, aged about 60, who had suffered from a slight attack of hemiplegia, had no defect in speech, but if he attempted to read either to himself or aloud—which he could do only with difficulty—the printed page conveyed absolutely no meaning to his mind.

This condition, which is termed also "alexia," is quite different from the simple inability to read aloud—cases of which are not infrequent. These cases of motor aphasia are specially interesting from the fact that sometimes they are only transient, but in this case the lesion was of a character that rendered the loss permanent and the patient succumbed to a second and more severe attack.

Dr. H. B. Hemenway, Evanston, Ill.:—I want to call attention to one point which seems to me to be very important, and that is the differentiation between true aphasia and the matter of education. It seems to me that Dr. Angear in his remarks has confused the lack of education with a diseased condition. As I understand it, aphasia is a diseased condition. Of course, a man may understand nothing of what we say for the simple reason that he has never been educated.

An Indian who has never learned our language, could not understand our conversation. In a like manner, a foreigner may be able to read English easily, but understand the spoken words slowly, or not at all. There is, as Dr. Angear has said, a great deal of difference between students. One student may pass a good oral examination, but not a good written one, for the simple reason that his preliminary education has been neglected. That is not a diseased condition, but it shows the lack of development. There are undoubtedly persons who have natural gifts in certain directions. These gifts are often the result of hereditary training, or education. It seems to me that pantomime is often the result of hereditary influences. I say hereditary because some nationalities exhibit the power far stronger than others. There are others, who on account of loss of speech, or of occupation are obliged to use pantomime. This power is the result of training, and compared with such persons an individual may be greatly lacking, and not be at all diseased.

Dr. L. Bremer, St. Louis, Mo.:—It is a fact that there are cases of pantomime without aphasia, and that in these cases localized lesions have been found in the inferior optic thalamus. I do not wish to enter into a lengthy discussion of this paper, but I simply wish to say that it has always seemed to me that in cases of aphasia there is some degree of mental weakness always present. When the subject was discussed in France in the early days of the aphasia question many held that the greater the aphasia the greater the mental defect.

Dr. C. H. Hughes, St. Louis, Missouri:—I hardly think that the statement, the greater the aphasia the greater the intellectual lesion, should be permitted to pass entirely unchallenged, as very much depends upon the condition which may have precipitated the aphasia. I do not see, when we are called upon to testify in court, how we can take the ground that a distinctively traumatic condition causing aphasia must necessarily produce mental impairment. It is true in the beginning of the aphasic attack where the cerebrum is largely implicated from the œdema which immediately follows an attack, that we find a large amount of concomitant mental enfeeblement, but as recovery reasserts itself, we find that nothing appears to remain in some of these cases, so far as my observation goes, but the simple fact of the aphasic lesion. I think we ought to be a little careful about promulgating a view upon this subject that will embarrass us before the courts. I believe that where persons have aphasia, from a circumscribed lesion that is traumatic or a lesion which is simply one involving the organ in sudden closure, we may have a purely local and limited aphasic lesion the result of adventitious change, or syphilitic cerebritis or embolus involving the middle cerebral artery, which of course would not in the nature of things be distinctively limited to the posterior aspect of the third left frontal convolution. While it is in the main correct to state that there is usually and in the beginning of the attack something more than the circumscribed mechanical embarrassment producing the aphasia, at the same time I believe there can be no doubt about the fact that there is such a thing as aphasia which is limited to the third left frontal convolution, the result of direct and limited local mechanical embarrassment, whether it be the depression of spicula of bone which is removable, the obstruction of an embolus or a lodged thrombus, leaving finally only aphasia without other mental failure; nevertheless, as a general rule the proposition is correct that you have accompanying enfeeblement, especially in the earlier stages of the disease, but the patient may recover from all but the speech failure.

Dr. C. K. Mills, Philadelphia, Pennsylvania:—Although the discussion has wandered a little sometimes from the particular matter of pantomime, I am gratified at the turns it has taken, as in nearly every case some point has been brought out bearing on this subject.

The question of the preservation or loss of pantomime in various forms of insanity, alluded to by Dr. Kiernan, is of great importance.

The remarks of Dr. Angear were interesting as emphasizing points which I did not emphasize enough. It is important, as remarked by Dr. Hemenway, in considering pantomime or any allied subject, to take into account in our studies not only the diseased state and the symptoms which are expressive of it, but also the original capacity of the individual, and his development or lack of development. Take, for example, the cases on which this paper was largely founded, cases which I have studied in the Philadelphia Hospital; many of them are persons of limited education, and have had no special manual, or other training of a higher sort; these facts must be weighed in discussing aphasic or mimic disorders. An actor or an orator, one who has his powers of pantomime highly developed, and one who has a good inheritance and original capacity, may recover speech and pantomime sooner or more fully than others.

With reference to the question discussed by Drs. Bremer and Hughes of aphasia and mental impairment, the gist of my paper would be largely to emphasize that which was emphasized yesterday in another connection, while we have all grades of mental loss in a theoretical sense, still practically it is necessary for us to study these cases as they present themselves. Pantomime, like defect in speech, is recovered from in varying degrees in the progress of a case of organic brain lesion. This point is one of great importance medico-legally, and should be borne in mind.

Functions of the Cord.—In the summer number of *Brain* Dr. Mott gives the result of observations and experiments he has made with the view of discovering the relations and functions of especially the ascending antero-lateral tract, commonly known as Gowers's tract in the spinal cord. In summarizing his results he states that the peripheral portion of the anterior and lateral columns consists in great part of ascending and descending cerebellar fibres. The former, the ascending, may be divided into a ventral and dorsal portion, and these should be named the ventral and dorsal ascending cerebellar tract instead of the antero-lateral and direct cerebellar tracts, the latter being the names by which they are now generally known. The ventral portion, it is said, may be completely divided in monkeys apparently without producing analgesia. The ascending cerebellar tract, he says, forms a connecting bridge between the superior vermis of the cerebellum and cells in the cord, the dorsal portion connecting the cells of Clarke's column with the dorsal part of the superior vermis, while the ventral portion connects certain cells of the cord with the ventral part of the superior vermis. Section of the antero-lateral column was found to produce much denser degeneration amidst the areiform fibres than could be accounted for by the slight injury to the direct cerebellar fibres. The extensive tract of degeneration corresponding to Gower's antero-lateral tract (which he thinks, with Löwenthal, should be called ventral cerebellar) has been traced in the monkey to the superior vermis by way of the superior cerebellar peduncle, forming in its course a curious loop over the fifth nerve.—*The Lancet.*

Therapeutic Application of Diuretin in Childhood.—Dr. Demme has given this substance to eleven children suffering from various forms of dropsy. He finds diuretin applicable in childhood from the end of the first year, a valuable diuretic and free from injurious action. The diuretic effect appears to be due to its action on the epithelium of the kidneys. The at times excessive dropsy of scarlet fever nephritis appears, after the expiration of the first acute stage of the nephritis, to be more quickly overcome by diuretin than by any other treatment. Dropsy from mitral insufficiency can generally, after compensation of the latter by digitalis, be quickly cured. The daily dose for a child two to five years old is 0.5–1.5 grams, from six to ten, 1.5–3.0 grams of diuretin best taken in 100 grams of water with the addition or ten drops of cognac and 2.5 grams of sugar. No cumulative action has been observed nor weakening of the therapeutic effect after several weeks' use.

Salol in Cholera.—The treatment for cholera proposed by Dr. Lœwenthal (first dose of two grams followed by hourly or half-hourly doses of one-half to one gram of salol), after experimenting with it in the laboratory and on animals, has been used on human beings with remarkable results. Dr. Gonzales, of Salvador, has used this treatment in 53 cases of cholera in one of the Philippine Islands with only three deaths (and these were already in the last stages of the disease when they came to treatment). The mortality under other modes of treatment is about 45 per cent.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 17, 1892.

DENTITION IN INFANTS.

A communication from the pen of H. C. WOOD, upholding gum lancing, and taking issue with the views of FORCHHEIMER, on the subject, as detailed in his recent book on the Diseases of the Mouth, has been copied very generally by the medical press of the country. This extensive republication may fairly be taken as expressive of a general approval of the position taken by PROF. WOOD.

Upon the questions of difficult dentition and gum lancing, the medical world has been for some years divided; the smaller party taking the modern view that dentition is a normal process and rarely if ever produces dangerous symptoms; the larger party holding that dentition is responsible for most of the ills that infants suffer from, and that gum lancing is its sovereign remedy. This latter view is one of our most ancient possessions, having come down to us from HIPPOCRATES. For centuries it remained unquestioned, and has consequently become firmly intrenched in both the professional and the lay mind.

JOHN HUNTER ascribed the following conditions to dentition: "Diarrhœa, costiveness, loss of appetite, eruptions on the skin, especially on the face and scalp, cough, shortness of breath, with a kind of convulsed respiration, and similar to that observed in whooping cough, spasms of particular parts either by intervals or continued, and increased and sometimes decreased secretion of urine, a discharge of matter from the penis, with difficulty in micturition, resembling symptoms of gonorrhœa in its violent form. The lymphatic glands are apt to swell at this time; if the child has a strong tendency to scrofula, this irritation will promote the disease. There may be many other symptoms with which we are not at all acquainted, the patients not being able to express their feelings."

Most, if not all of these symptoms are attributed to teething to-day.

Perhaps the earliest opposition to these views was by ROSEN VON ROSENSTEIN, in the middle of the last century; but his opposition was only partial. But WICHMANN in 1800 expressed the true status of dentition when he said: "It is to be hoped that, in the future, dentition will be called up only when it would be impossible to comfort the relatives with the impotence to designate the true nature of the disease, or to quickly calm the laity."

BILLARD, who was a careful student of pathological anatomy, particularly with reference to infancy, found nothing to impress him with the importance of dentition.

As we look over the list of symptoms given by HUNTER we find that many of them can be explained much more rationally by the results of modern positive observation. Diarrhœa has been shown to be intimately connected with fermentative processes; the respiratory symptoms are those commonly met in rickets, and in cases of pharyngeal adenoids; the convulsions are probably due to rickets; and the enlarged glands are tuberculous.

During the past summer this subject has occupied somewhat the attention of the Academy of Medicine of Paris. At the meeting of July 12, MAGITOT said "We wish that the so-called diseases of dentition, might be definitely erased from our medical nosology."

This brought a reply from M. PAMARD on August 9, who took the following ground:

1. All difficult dentition is accompanied by a disturbance of the health of the infant.
2. In cold climates, and in cold seasons, all difficult dentition is accompanied by reflex phenomena on the part of the respiratory organs. In warm climates and in warm seasons, all difficult dentition is accompanied by reflex phenomena on the part of the digestive organs.
3. The diseases allied to dentition in the infant, pursue a course, and present characteristics, which are clearly defined and well established.

These propositions were supported only by the old argument of coincidence, but the essayist was upheld by MM. LE ROY DE MERICOURT, HERARD, CHARPENTIER, PETER, and CONSTANTIN PAUL. He was opposed by MM. OLLIVIER, and HARDY.

In the study of this question, it is first necessary to separate dentition and gum-lancing. The first is a possible pathological condition, while the second is a therapeutic procedure.

We think it can be said without fear of contradiction, that there is not a single positive observation which has ever been recorded to prove that dentition produces general or reflex symptoms. It is undeniable that at the period in life when dentition is in progress, the infant is subject to certain disorders which occur much more commonly than at any other period of life.

If it could be shown that dentition was the only peculiarity of the infant, then its causative influence would be clear. But dentition is not the only peculiarity of the infant, and co-existing phenomena can only be classed as coincident. The most profound characteristic of infancy is that it is the period of most rapid growth and development of all organs; and careful observation of infants reveals numerous and great deviations from the normal growth and development in many instances. It will probably not be denied that such deviations are found most commonly in infants who have been artificially fed. In infants improperly fed, and this term is too extensive to attempt to define here, reflex manifestations are very readily produced, and it is not improbable that even a normally developing tooth may, in such an infant, be the exciting cause of trouble. We have seen infants, who would invariably have a bronchial attack immediately before the proruption of a tooth, but they have invariably been infants who were suffering from demonstrable deviations from normal nutrition. We have further found that after improving the nutrition of these infants, the further progress of dentition was unaccompanied by symptoms.

In such cases while it would be just as well perhaps to recognize the possible influence of dentition, its subordinate importance should be kept clearly in view. The great danger of teething is in the diagnosis, for when this is once made, the important underlying conditions are apt to be neglected, and permitted to progress to the death of the child.

Dentition is a convenient scape goat, and OLLIVIER has well said in the discussion just referred to: "During the nearly ten years that I have been connected with the Hospital for Sick Children, it has often happened that children brought to me for diseases of this type (teething) have been found to be suffering with an altogether different affection. It is very easy to invoke this diagnosis, but by passing in review the different organs and apparatuses, the diagnosis can easily be rectified."

But if dentition cannot be shown to be the great etiological factor of infantile disorders, it does not follow that gum lancing should be abandoned. It is difficult to overlook the numerous instances in which careful observers have thought they have obtained good results from its use, but it would be well also to bear in mind the many cases in which it has failed. As a therapeutic procedure it may have some value, but the indications for its use must be sought elsewhere than in a supposititious condition of teething. We should like to offer the following conclusions:

1. Before the diagnosis of "teething" is made, there should first be carefully excluded, organic disease of all organs, infection, intoxication, and perversion of nutrition.

2. Gum lancing as a therapeutic measure should stand on its own merits, and be studied apart from any supposititious and undemonstrable process of teething.

DISINFECTION THAT DOES NOT DISINFECT.

The value of any disinfecting process can be estimated only on the basis of experiments with the known germs of a given disease. The random directions which were more or less vaguely followed before KOCH's accurate work, involved not merely an enormous waste of labor and money but gave no guarantee that their object was really obtained, that is to say, that the germs were killed. Since the painstaking researches by KOCH and his pupils, work continued in this country by STERNBERG, PRUDDEN, and others, we known just how to destroy the germs of a given disease in the cheapest and most efficient manner. It is, therefore, a matter for severe censure if vague and inefficient measures are used by parties whose business it is to know what has been done in this line.

The frequent references of the public press to fumigations with sulphur show that many sins are yet committed in the practice of disinfection. No more flagrant instance however, of inefficient disinfection has come to our notice, than the directions issued by the New York Board of Health and reprinted without comment by the *New York Medical Record.*

A sulphate of iron solution in the strength of 1½ parts to 8 of water is advised for the disinfection of cellars, yards, stables, cesspools, sewers and so on. The accurate work above referred to has proven beyond doubt that this substance has feeble disinfecting powers at the best, and is altogether valueless in the manner recommended by the Board.

A zinc solution made by dissolving 4 ozs. of sulphate of zinc and 2 ozs. of salt in 1 gal. of water is directed to be used for disinfecting clothing, bed linen and so on. It has never been shown by any one that this has any disinfecting power whatsoever. In the latter part of the circular it is directed to boil clothing in this solution. While this of course is an efficient measure, what advantage is there in this fluid over pure boiling water? It has been shown that boiling soda solution acts more quickly even than pure water, but no such proof has ever been given of the efficiency of the zinc solution.

Corrosive sublimate solution 1 per 1000 is likewise recommended. But the strong germicide properties of this substance are counter-balanced by its tendency to form precipitates with albumenoids and other organic material and direct experimentation has shown that it is not a reliable agent for the disinfection of discharges. In reference to this as well as to the other substances mentioned in the circular we fail to find any mention of the importance of time in the process of disinfection. No one not fully familiar with *disinfection methods* could obtain reliable results by following the loose directions given.

The circular ends with a totally unjust praise of sulphur fumigation. Over and again it has been shown that sulphurous acid is not at all germicidal when dry and that even when moist it permeates larger articles very imperfectly. Under the best conditions attainable on a small scale in the laboratory sulphur fumigations are unreliable, while under the conditions existing in ordinary rooms the concentration of the fumes sinks speedily to such a level that the procedure is *totally valueless*.

CHOLERA.

The stringent quarantine measures carried into effect at our Nation's ports of entry, have been signally successful thus far in preventing the introduction or development of a single case of cholera in this country. This is a magnificent triumph for State medicine and sanitary science.

Unfortunately, there has been a considerable amount of friction between the National, State and local authorities, as to the powers of each in the enforcement and regulation of quarantine measures, clearly demonstrating the vital necessity for a Cabinet Officer of Public Health, whose rulings should have all the force and effect of enacted law.

Medical science has so far perfected our knowledge of the habits of the present threatening invader, as to enable the quarantine officers to hold the disease at bay. This has been done with such imperfect regulations as to involve very great hardship, sickness and death to many hundreds of people in the quarantined vessels. While these regulations are apparently justifiable, a single head with unquestioned power and authority, would be able to do all that is necessary, and with a show of mercy to the unfortunate passengers on quarantined vessels.

* * * * * *

Hamburg vessel owners cannot be too strongly condemned for sending their infected ships carrying thousands of passengers to our shores. The captains of these vessels seem to have never thought of the propriety of turning about, and carrying back their loads of living freight to the harbors from whence they sailed. If there are no laws for the penal punishment of such ship captains, such laws should be enacted as speedily as possible.

* * * * * *

The enactment by Congress, of stringent immigration laws, to limit, if not to effectually stop the use of American ports as a common dump for the use of the other nations of the earth will meet with universal approval.

We concede the ability of the American people to absorb, assimilate and utilize nearly everything that comes to them, but the line must be drawn, and this is *a good time to do so*. Let it be made so strong and plain that every Hamburg or other ship owner can understand it, and that without an interpreter.

EDITORIAL NOTES.

Errata.—On page 285, 17th line from top of first column the word *anterior* should be *interior* and 36th line from top of same column *ten* instead of *two* years.

Canadian Medical Association.—We have received from Dr. Herbert S. Birkett, secretary of the Canadian Association, an invitation to attend the twenty-fifth annual meeting at Ottawa. There will be a three-day session, on September 21 to 23, under the presidency of Dr. John L. Bray of Chatham. Dr. Donald Maclean of Detroit, has been invited to deliver the address in surgery. The address in medicine will be given by Dr. Graham, of Toronto. The customary arrangements with railway officials have been made, as shown by the following, taken from the members' notification: "Arrangements have been made with the Grand Trunk and Canadian Pacific Railways whereby members and delegates may obtain return tickets for one fare and one-third. Members and delegates will please bear in mind certificates entitling them to reduced rates *are to be obtained from the station agent at the place of departure*; one full fare is to be paid, and upon presentation of the certificate on the return journey, a ticket will be issued at one third of full fare."

The Re-vaccination of Soldiers.—In 1890, not one case of small pox was reported to have occurred in the British Army. This is evidence of the protection of re-vaccination against a malady once so fatal to armies, and still very disastrous where the measure is inefficiently carried out. Even in the armies and navies of Europe wherein the rules of re-vaccination have been administered vigorously mortality by small-pox has not been wholly eluded. The British Navy especially has found it a difficult matter to exclude mortality from this cause. The Prussian army has an enviable record in this regard, being able to show not more than 100 cases by death, from this cause, in a period of forty years.

Salophen in Rheumatism.—Dr. William H. Flint, of New York City, has had an opportunity to try this remedy at the Presbyterian Hospital, following out the suggestion of Dr. Guttmann of Berlin, made in 1891. The cases were chiefly acute attacks. The drug was administered in fifteen grain doses, put dry upon the tongue, and followed by a swallow of cool water, every three hours; and with sodium bicarbonate in ten grain doses thrice daily. Dr. Flint's report of the treatment may be found in the *New York Medical Journal* for July 30. There was a reduction of *dolor*, *rubor* and *calor* in five out of six cases on the second or third day of the treatment. In the view of the author, the dosage might properly have been larger and prompter relief obtained, but he was desirous of moving in a conservative manner. The heart's action was not weakened nor the stomach upset in any of these cases. There was no distinct effect upon the urinary excretion. No relapses and no cardiac nor pleuritic intercurrences were observed. From these facts the author believes that salophen ranks highly, along with other salicylates, as a potent medicine for acute rheumatism, and has this advantage, over some of the other drugs, that the new treatment does not enfeeble the heart, disturb the stomach nor produce smoky and albuminous urine. Judging from the experience of Dr. Flint the rheumatic pyrexia may be expected to fall to very nearly the normal within twenty-four to thirty-six hours after the first administration. If this experience finds confirmation in trials that are about to be made by the writer and others, the treatment will undoubtedly be "pushed" with the view of bringing down the "febrile movement" even earlier than has yet been done. The remedy appears to be among the safest of the new synthetic preparations.

A New Disinfected Chirurgical Leather or Artificial Chamois.—A very learned German chemist and naturalist has invented a new process of mineral tanning by which a beautiful chamois leather is made from sheep skins. It is tanned with a substance absolutely harmless and not decomposed nor injured by washing in soap suds. It can be soaked with any disinfectant without harm to the quality of the leather. It is claimed that bacterial life and fungoid growths are not produced by long contact of this leather with the human body surface. Very desirable for bandages, artificial limbs, harnesses, eczema, etc. In oil and alum tanned leathers the animal fiber is still liable to decomposition. The oil or alum can be removed by washing or by extraction while the fiber remains in a more or less crude and decomposed or decomposable condition. Ordinary surgical leathers kept in contact with the body of the sick, prove to be nests of bacteria. This leather does not as, 1, The animal fiber is in a neutralized condition or combination with the tanning material and cannot be extracted: 2, The tanning material combined with the fiber, being neither decomposable nor alterable at all, produces one of the most stable compounds known; 3, The *tanning material* is widely diffused in Nature, is one of the essential elements of animal life and not noxious like decomposed and decomposing oil or alum. The samples can hardly be distinguished from chamois. Finer sorts are produced from goat and deer skins.

DOMESTIC CORRESPONDENCE.

To the Editor of the Journal of the American Medical Association:

I desire to call the attention of those who have served as Acting Asst. Surgeons U. S. Army either during or since the War of the Rebellion, to the fact that an Asssociation of Acting Asst. Surgeons U. S. Army was organized in 1868. All past and present Acting Asst. Surgeons are cordially invited to become members, and the addresses of those resident in Chicago, Milwaukee and Cincinnati are especially desired. Circulars can be obtained by addressing the undersigned. Very truly yours,

W. Thornton Parker, M.D.,
Recorder Assoc. Acting Asst. Surgeons.

2220 Wabash Ave., Chicago, Sept. 13, 1892.

SELECTIONS.

A Boom in Lysol.—The chief Sanitary Board of Austria has published, apropos of cholera, a statement regarding the value of some new disinfectants, in which it draws special attention to lysol. It says that the drug is speedily destructive to the comma bacillus, but is much less poisonous to man than is carbolic acid. A further advantage which lysol possesses over carbolic acid as a disinfectant of the hands, linen, etc, is that a solution of it renders the skin smooth instead of rough.—*Medical Record.*

Contagion through Flies.—If, as it appears to have been proven by experiment, flies may be the means of disseminating anthrax. tuberculosis and other infectious diseases, they should be objects of especial suspicion during an epidemic of cholera. They should be excluded from the house as far as possible, and all articles of food and drink should be protected by screens from contamination by them.—N. Y. *Med. Record.*

A Coryza Snuff is thus formulated in the French journal *L'Union Medicale*: Naphthalin,in an impalbable powder ʒ vi.; powdered boracic acid, ʒ vj.; powdered camphor, gr. xv.; extract of violets, gr. xv.; essence of roses, gtt. xx. Sig. Mix, and use as a snuff in coryza.

MISCELLANY.

American Rhinological Association.—Programme of exercises of the ninth annual meeting of the American Rhinological Association, to be held at The Denison, Indianapolis, Ind., September 20 and 21, 1892. The profession is cordially invited to attend the meetings of the Association.

1. Reading of Minutes of Council Meeting; 2. Report of Secretary and Treasurer; 3. Report of Librarian; 4. Reports of Committees; 5. Examination of Theses of Applicants for Fellowship; 6. Balloting for Candidates; 7. Miscellaneous Business.

1. Address of Welcome, E. R. Lewis, M.D.

EMBOLISM OF THE CENTRAL ARTERY OF THE RETINA, WITH THE REPORT OF THREE CASES.

Read before the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, at Detroit, Mich., June 7, 1892.

BY G. E. de SCHWEINITZ, M.D.,

Professor of Diseases of the Eye, Philadelphia Polyclinic, Lecturer on Medical Ophthalmoscopy, University of Pennsylvania, Ophthalmic Surgeon to the Philadelphia and Children's Hospitals, Etc.

Since 1859, when Von Graefe observed the first case in which there was almost instantaneous blindness from obstruction to the central retinal artery, until the present time, a great number of examples of this condition have been placed upon record. In 1885, Schnabel and Sachs (*Archives of Ophthalmology*, Vol. xiv, p. 298) were able to refer to 102 cases published to date, and in the years which have followed at least 32 additional instances have been added to the literature of medicine. Indeed, the entire subject has recently been reviewed in great detail in an elaborate monograph by R. Fisher, "Ueber die Embolie der Arteria Centralis Retinæ," Leipzig, 1891. In spite of these records, the explanation of certain phenomena seen in connection with this accident remains in dispute, and each new carefully observed case contains elements of interest worthy of publication, either because it places at our disposal additional facts, or because it tends to confirm former observations.

Case 1.—Embolism of the Left Central Artery of the Retina. Ophthalmoscopic Examination Twenty Minutes after the Obstruction. April 7, 1891. C. R., a man aged 26, while standing on the street conversing with a friend, without premonition, was suddenly completely blind in the left eye. The absolute character of the loss of vision is attested by the fact that after closure of his unaffected eye, he was unable to perceive the faintest ray of light from an electric lamp situated directly opposite to him. He came almost at once to my office and was examined (10:20 P.M.) twenty minutes after the occurrence. He was pale, complained of a feeling of faintness and vertigo, the pulse was 75, rather strong and bounding, and there was a coarse mitral systolic murmur transmitted to the axilla. Vision in O. D. 6÷6; in O. S. *nil.* The pupils were equal in size, the left unaffected by light, but acting consensually with the other. *Ophthalmoscope.* The oval optic disc, superficially pinkish-gray in tint, but distinctly pallid in its deeper layers, was surrounded by a partially absorbed choroid ring, within which the connective tissue ring could be traced all round. The coloring of the disc was visible through a semi-transparent, delicate haze which covered its surface and spread out into the retina in a circular area of about a disc's diameter; here the color of the haze was more decidedly gray. The macular region was invested with a similar, but more milky haze, and in the centre there was a typical *cherry spot.* These two banks of fog were separated by an area of unaffected retina. The entire arterial tree had very much dwindled, the vessels being represented by faint, rosy threads on which no light reflex could be traced. There was no anomalous vessel. The shrinking of the arteries perceptibly increased during the ophthalmoscopic examination. In contrast, the veins seemed larger, although as compared with the other side, they were smaller than normal. In the lower temporal vein a moderately rapid circulation was visible, characterized by small cylinders of blood separated by clear spaces which moved towards the disc, giving very much the appearance that would be produced by mixing air and colored water in a tube. Rapid and vigorous massage of the eyeball produced no effect upon the embolus and no material change in the ophthalmoscopic appearances, and a current of blood was not developed in the arteries by this manipulation. The ophthalmoscopic examination, which lasted for ten or fifteen minutes, was abruptly terminated because the patient fainted, or at least became so faint that he could not sit upright.

April 8, 1891. The patient was seen at his house under circumstances that made a prolonged examination with the ophthalmoscope well nigh impossible. The chief change which had taken place was the deepening of the milky-white infiltration of the retina. The cherry spot remained as before, the arteries were still small, but not so small as on the previous day, and the beaded circulation in the vein had ceased. There was now faint light perception.

April 10, 1891. The disc was quite pallid, in fact, it was materially obscured by the deepened milky infiltration, the peri-papillary portion of which had joined the macular bank, so that there was no intervening layer of unaffected retina.

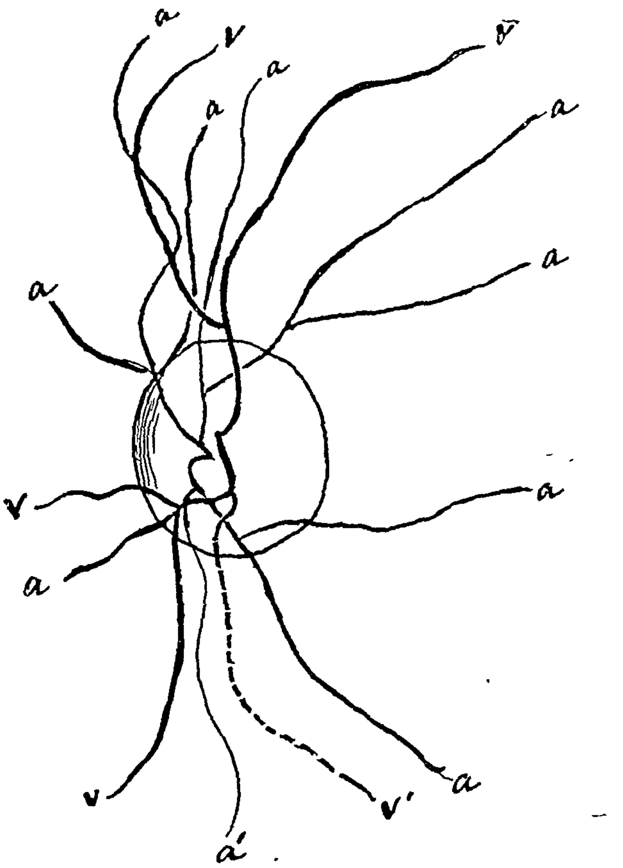

Figure 1.—Representing the retinal veins and arteries after the primary shrinking had given place to increase in diameter; a, artery; v, vein; a', artery which remained small; v', vein which exhibited beaded circulation. *No attempt has been* made to show the œdema.

April 20, 1891. The area of infiltration remained about may be expected to fall to very nearly the normal within twenty-four to thirty-six hours after the first administration. If this experience finds confirmation in trials that are about to be made by the writer and others, the treatment will undoubtedly be "pushed" with the view of bringing down the "febrile movement" even earlier than has yet been done. The remedy appears to be among the safest of the new synthetic preparations.

A New Disinfected Chirurgical Leather or Artificial Chamois.—A very learned German chemist and naturalist has invented a new process of mineral tanning by which a beautiful chamois leather is made from sheep skins. It is tanned with a substance absolutely harmless and not decomposed nor injured by washing in soap suds. It can be soaked with any disinfectant without harm to the quality of the leather. It is claimed that bacterial life and fungoid growths are not produced by long contact of this leather with the human body surface. Very desirable for bandages, artificial limbs, harnesses, eczema, etc. In oil and alum tanned leathers the animal fiber is still liable to decomposition. The oil or alum can be removed by washing or by extraction while the fiber remains in a more or less crude and decomposed or decomposable condition. Ordinary surgical leathers kept in contact with the body of the sick, prove to be nests of bacteria. This leather does not as, 1, The animal fiber is in a neutralized condition or combination with the tanning material and cannot be extracted: 2, The tanning material combined with the fiber, being neither decomposable nor alterable at all, produces one of the most stable compounds known; 3, The tanning material is widely diffused in Nature, is one of the essential elements of animal life and not noxious like decomposed and decomposing oil or alum. The samples can hardly be distinguished from chamois. Finer sorts are produced from goat and deer skins.

EMBOLISM OF THE CENTRAL ARTERY OF THE RETINA, WITH THE REPORT OF THREE CASES.

Read before the Section of Ophthalmology, at the Forty-third Annual Meeting of the American Medical Association, at Detroit, Mich., June 7, 1892.

BY G. E. DE SCHWEINITZ, M.D.,

Professor of Diseases of the Eye, Philadelphia Polyclinic, Lecturer on Medical Ophthalmoscopy, University of Pennsylvania, Ophthalmic Surgeon to the Philadelphia and Children's Hospitals, Etc.

Since 1859, when Von Graefe observed the first case in which there was almost instantaneous blindness from obstruction to the central retinal artery, until the present time, a great number of examples of this condition have been placed upon record. In 1885, Schnabel and Sachs (*Archives of Ophthalmology*, Vol. xiv, p. 298) were able to refer to 102 cases published to date, and in the years which have followed at least 32 additional instances have been added to the literature of medicine. Indeed, the entire subject has recently been reviewed in great detail in an elaborate monograph by R. Fisher, "Ueber die Embolie der Arteria Centralis Retinæ," Leipzig, 1891. In spite of these records, the explanation of certain phenomena seen in connection with this accident remains in dispute, and each new carefully observed case contains elements of interest worthy of publication, either because it places at our disposal additional facts, or because it tends to confirm former observations.

Case 1.—Embolism of the Left Central Artery of the Retina. Ophthalmoscopic Examination Twenty Minutes after the Obstruction. April 7, 1891. C. R., a man aged 26, while standing on the street conversing with a friend, without premonition, was suddenly completely blind in the left eye. The absolute character of the loss of vision is attested by the fact that after closure of his unaffected eye, he was unable to perceive the faintest ray of light from an electric lamp situated directly opposite to him. He came almost at once to my office and was examined (10:20 P.M.) twenty minutes after the occurrence. He was pale, complained of a feeling of faintness and vertigo, the pulse was 75, rather strong and bounding, and there was a coarse mitral systolic murmur transmitted to the axilla. Vision in O. D. 6÷6; in O. S. *nil*. The pupils were equal in size, the left unaffected by light, but acting consensually with the other. *Ophthalmoscope.* The oval optic disc, superficially pinkish-gray in tint, but distinctly pallid in its deeper layers, was surrounded by a partially absorbed choroid ring, within which the connective tissue ring could be traced all round. The coloring of the disc was visible through a semi-transparent, delicate haze which covered its surface and spread out into the retina in circular area of about a disc's diameter; here the color of the haze was more decidedly gray. The macular region was invested with a similar, but more milky haze, and in the centre there was a typical *cherry spot*. These two banks of fog were separated by an area of unaffected retina. The entire arterial tree had very much dwindled, the vessels being represented by faint, rosy threads on which no light reflex could be traced. There was no anomalous vessel. The shrinking of the arteries perceptibly increased during the ophthalmoscopic examination. In contrast, the veins seemed larger, although as compared with the other side, they were smaller than normal. In the lower temporal vein a moderately rapid circulation was visible, characterized by small cylinders of blood separated by clear spaces which moved towards the disc, giving very much the appearance that would be produced by mixing air and colored water in a tube. Rapid and vigorous massage of the eyeball produced no effect upon the embolus and no material change in the ophthalmoscopic appearances, and a current of blood was not developed in the arteries by this manipulation. The ophthalmoscopic examination, which lasted for ten or fifteen minutes, was abruptly terminated because the patient fainted, or at least became so faint that he could not sit upright.

April 8, 1891. The patient was seen at his house under circumstances that made a prolonged examination with the ophthalmoscope well nigh impossible. The chief change which had taken place was the deepening of the milky-white infiltration of the retina. The cherry spot remained as before, the arteries were still small, but not so small as on the previous day, and the beaded circulation in the vein had ceased. There was now faint light perception.

April 10, 1891. The disc was quite pallid, in fact, it was materially obscured by the deepened milky infiltration, the peri-papillary portion of which had joined the macular bank, so that there was no intervening layer of unaffected retina.

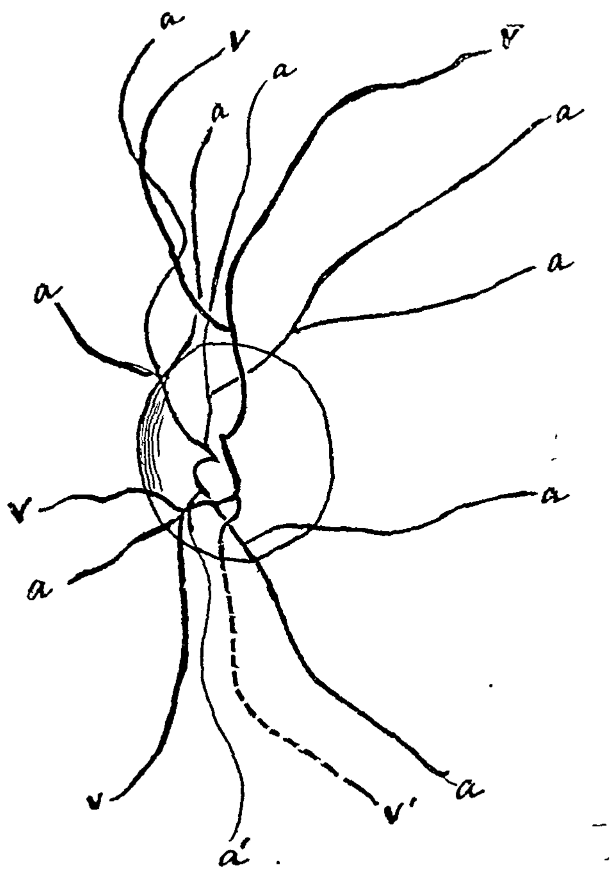

FIGURE 1.—Representing the retinal veins and arteries after the primary shrinking had given place to increase in diameter; a, artery; v, vein; a', artery which remained *small*; v, vein which exhibited beaded circulation. No attempt has been made to show the œdema.

April 20, 1891. The area of infiltration remained *about* the same. The retinal veins were full, and of apparently normal size, while the arteries had materially increased in diameter, and, with the single exception of the inferior temporal artery (which was only a faint thread), could be traced for some distance out into the retina, but were finally lost in the foggy infiltration. (See Fig. 1.) The light perception in the centre of the field was a little more marked. The patient was not seen after this for nearly a month.

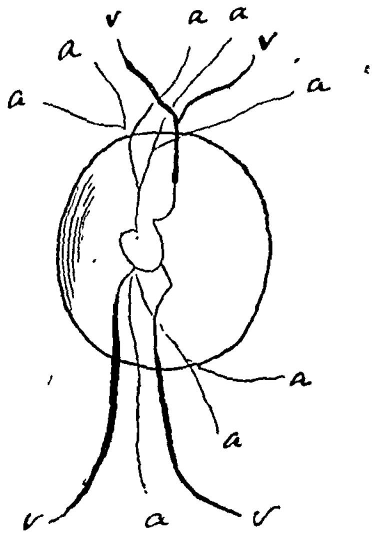

Figure 2.—Representing the retinal veins and arteries 35 days after the occurrence of the embolism. The arteries are mere threads, and are lost soon after crossing the disc. The veins are dark and large in contrast, except in the venous circle on the disc; a, artery; v, vein.

May 12, 1891. The oval optic disc was of a greenish pallor, entirely devoid of capillaries. All the arteries were faint threads scarcely distinguishable upon the disc, and lost entirely, or traceable only as minute whitish lines, after they had passed the margin for less than half a disc's diameter. (Fig. 2.) The veins were also shrunken, but in contrast to the arteries appeared darker than normal. The fog-like infiltration previously described had entirely disappeared, while in the macula was clustered quite a mass of cholesterin crystals. There was not the faintest ray of light perception.

Further data in regard to the clinical history of this patient and his previous cardiac conditions are contained in the following letter received from his physician, Dr. William Pepper: "The cardiac lesion in C. R.'s case evidently dates back a number of years. I was first consulted about it in 1887, when I found a marked mitral regurgitation with a strong systolic murmur and a moderate degree of hypertrophy, not more than enough to effect good compensation. This condition has continued to the present time. He has been subjected to a great deal of care and physical, mental and emotional strain. The heart has borne it fairly well. During this winter there was some increasing anæmia, with a strong tendency to rapid action of the heart and to general weakness of the system. There was also slight feverishness from time to time. This was much improved by complete rest for short periods. In the summer of 1890, when in a location quite free from malaria, he had a series of severe chills, followed by a high fever of short duration. There has been a slight return of this during the present month, May, 1891. Are these truly malarial, or can they be connected with slight points of ulceration which might favor the detachment of a fragment of vegetation? In favor of the malarial view is the fact that the chills have yielded promptly to full doses of quinine."

Some time after the embolism, or in the early summer of 1891, this patient developed a popliteal aneurism, for the cure of which he finally underwent the operation of ligation of the femoral. Afterwards an aneurism appeared in the course of the brachial artery. Preceding the development of these aneurisms, he had an attack of rheumatic fever, or at least an attack which was thus diagnosticated.

Remarks.—The sudden onset of the blindness, the classical symptoms of acute anæmia of the retina from obstruction of the central artery, and the cardiac and vascular disease in this patient, render it more than probable that the lesion was an embolus. Some interest attaches to the opportunity of observing the ophthalmoscopic changes so soon after the lodgment of the obstructing body. The picture did not materially differ from that which has often been described, but it is interesting to note how rapidly the œdematous change may occur in the retina after it has been deprived of its blood supply. The formation of two areas of infiltration separated by a band of comparatively unaffected tissue, is not readily explained, unless it be assumed that this region was not deprived of its blood supply.

The second point of interest in this case is one that has been noted in other instances, namely, that although the primary effect was to obliterate vision absolutely, and that at first the retinal arteries dwindled away to mere threads, after a time, beginning about seventeen hours after the lodgment of the embolus, the arteries increased in size, and so long as twelve days afterwards, with the exception of the inferior temporal artery, remained of considerable magnitude. During this period of the increase in the size of the vessels, there was faint light perception; in fact, on the day immediately following the accident, the patient declared that he could tell an object passed in front of his eye. Gradually, however, this return of sight disappeared, the arteries shrank, and the eye became absolutely blind.

Schnabel and Sachs have dwelt considerably upon this point, and enforced their observations with one autopsy. According to them, after a *partial* embolism of the trunk of the central artery, there are two causes which interrupt the circulation: one is the embolus itself, and the other is the spasmodic contraction of the walls of the artery. The latter gradually disappears, and then the vessels become filled again without there having been any change in the character of the embolus itself. The ultimate deterioration of vision, or its complete loss, depends upon the fact that there is no change in the position of the embolus. These observers believe that there is only one symptom which will decide whether an embolus partially or completely obstructs the flow of blood. It is partial if there is fulness of the vessels, or if there is circulation of the blood as indicated by the movement of the blood in the right direction seen after the embolism has occurred. The presence or absence of vision is of secondary importance in this respect.

Case 2.—Embolism of the Right Central Artery of the Retina. Examination Five Months after the Accident. Partial Preservation of the Temporal Field of Vision. S. H., a man aged 72 years, presented himself for examination October 22, 1890, with the following history: In May, 1890. when feeling perfectly well, with no premonitory symptoms, and while standing at his dressing case in the morning, he suddenly appreciated that the sight of the right eye was blotted out. No exact data are at hand from which to decide the completeness of the loss of vision, but from his own account and from that of his most intelligent family physician, it is probable, for many hours at least, that the obliteration was absolute. No one was at hand to make an ophthalmoscopic examination, but the patient was put to bed, purged, given sedatives, and his temple was leeched. After a time he began to see slightly, but did not find it convenient to consult any one until the date just mentioned.

He had always been a healthy man until about the time of the embolus, when his doctor discovered some sugar in the urine. This appears to have been a temporary condition, and when I examined him there was neither sugar, albumin, nor tube casts. There was high arterial tension; the temporal and radial arteries were distinctly hard to the touch. There was no increase in the area of cardiac dulness; the first sound was somewhat muffled and the second sound clanging. There was no murmur.

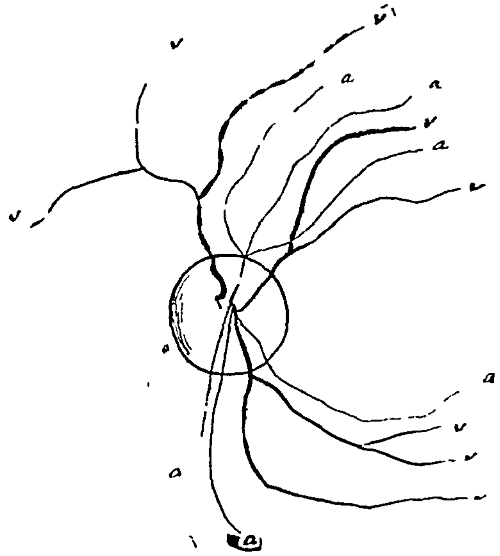

FIGURE 3.—a, artery; v, vein; v', beaded vein. A diagrammatic sketch. No vessel passes to the temporal side, and fine, transverse branches are absent. T, temporal side; N, nasal side.

Ophthalmoscope. The optic disc was nearly round,entirely atrophic, being of a greenish-white color. The arteries, where they could be traced, were mere threads, and none could be followed to the temporal side. The veins in contrast were dark, and the upper temporal vein, or at least the main branch of it, was beaded, dark, well filled portions being divided from each other by entirely collapsed areas. The finer tranverse branches could not be seen anywhere. (Fig. 3.) The vision in this eye consisted in object perception in the temporal portion of the field. In the left eye the vision, after correction of a slight astigmatism against the rule, was 6÷6. There were faint opacities in the anterior cortex of the lens, an oval, normally colored optic disc, and no changes in the central circulation.

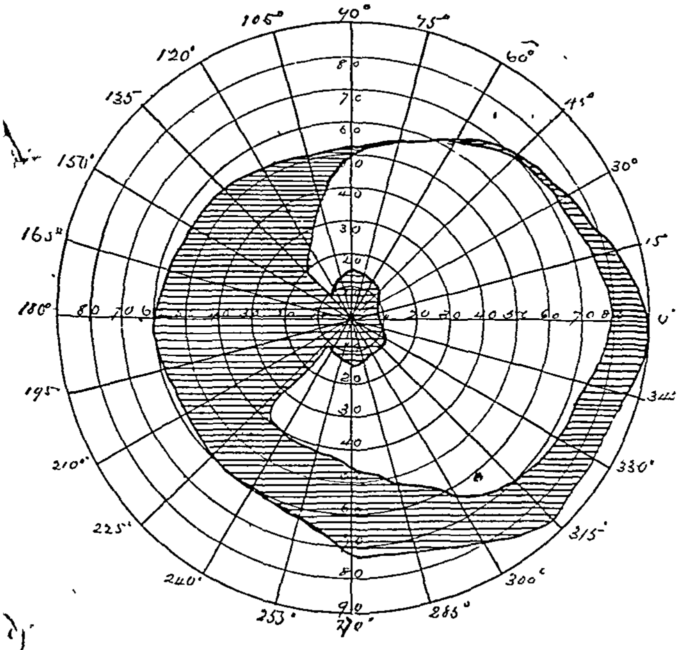

FIGURE 4.—Diagram of the field of vision of Case 2. The shaded area represents where vision was lost; the unshaded area, where there was preservation of form-sense.

The field of vision of the affected eye is represented in the diagram. (Fig. 4.) The shaded portion indicates the area in which vision was lost and the white portion the preserved field.

It will thus be seen that the greater portion of the nasal field is wanting, and that the centre of the field of vision is sharply cut out by an area thirty degrees in its long diameter, which on the nasal side joins the general obliteration of the inner portion of the field of vision. In the area of preserved vision light-sense and form-sense remained; color-sense was wanting.

Remarks.—The case which follows has many features analogous to those in the one just reported; indeed, it may be looked upon as a study of the symptoms which were probably present in the early stage of the affection in Case 2. For this reason I will defer the remarks until I have quoted Case 3.

Case 3.—Embolism of the Left Central Artery of the Retina. Examination Fifteen Hours after the Accident. Preservation of a Small Patch of the Temporal Field. Mrs. E. E., aged 66, presented herself for examination May 1, 1892, at about 2 o'clock in the afternoon. Fifteen hours before she appreciated that she had suddenly become blind in the left eye. There was a slight aura preceding the extinguishment of sight, characterized by what the patient called a "glimmering before the eye", probably some form of photopsy. The patient was in good health, had suffered no recent illness, but had done a good deal of stooping on the previous day, particularly in the act of gardening.

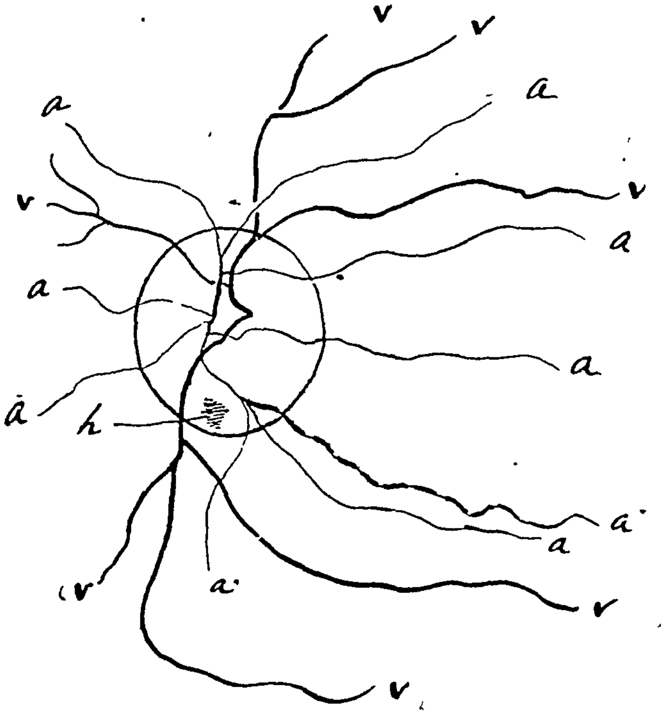

FIGURE 5.—v, veins; a, artery; a', beaded artery, carrying blood of darker color than that in the other branches, and resembling a vein; h, hæmorrhage in the disc.

When examined the vision amounted to faint light perception in a small area of the temporal half of the field. The optic disc was oval, distinctly gray or gray-red in color; all of the arteries were subnormal in size, but of a fairly normal color, with the single exception of a large branch of the inferior temporal artery, which, from its point of origin from the main trunk near the lower margin of the disc, as far as it could be followed in its curve along the lower temporal retina, was beaded, and appeared as if a series of constrictions had been placed around it. Moreover, in contrast to all of the other arteries, it carried much more darkly colored blood, so much so that at the first examination it was thought to be a vein. (Fig. 5.) There was a faint milky haze, most marked between the macula and the disc, and the fovea was represented by a dull, brownish-red spot showing through the fog. There was a small hæmorrhage on the disc lying between the inferior temporal artery and vein.

May 2, 1892. A careful map of the field of vision was obtained with the result which is exhibited in the diagram. (Fig. 6.) It will be observed that a small patch remains upon the temporal side, and that the centre of the field of vision is sharply cut out, in fact, that the general appearance of the map is closely similar to the one obtained in the previous case. In the area of preserved field light-sense remained, but form-sense and color-sense were absent. The ophthalmoscopic appearances were about the same as on the previous day.

May 16, 1892. It is unnecessary to give the daily record of the ophthalmoscopic appearances in this case; suffice it to say that gradually the haze disappeared and the disc became more and more atrophic. Today the following note was made: Disc uniformly gray and devoid of finer capillaries; only one small macular branch visible and one small vessel on the nasal side of the papilla; the veins are about the same size as the arteries, in fact, the upper temporal veins are smaller than the arteries, but both systems are diminished in size. The beading of the lower temporal artery continues. The hæmorrhage on the disc has been absorbed.

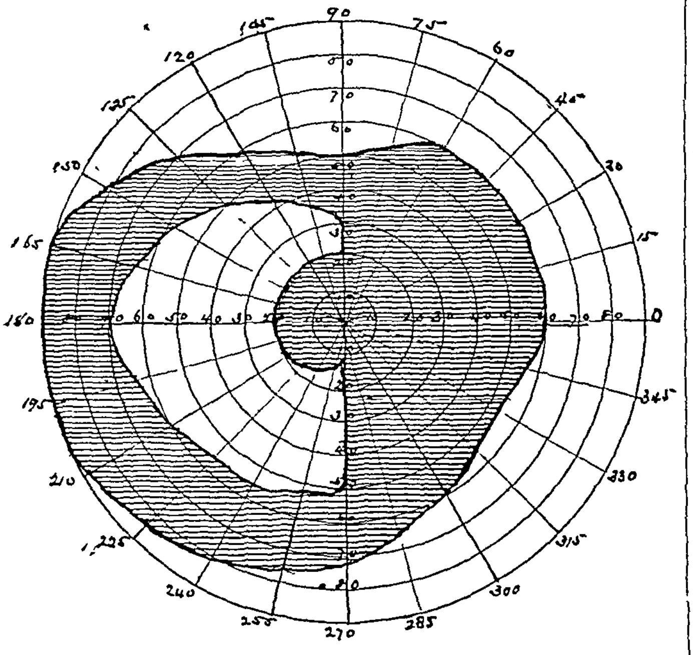

FIGURE 6.—Diagram of the field of vision in Case 3. The shaded area represents where vision was lost, the unshaded area, where there was preservation of light-sense.

May 24, 1892. Still greater atrophy of the disc. The upper temporal artery for about a disc's diameter above the papilla is obliterated, and then continues as a fine thread. The other vessels are about the same.

The family physician, Dr. James B. Walker, has kindly reported upon the condition of the heart as follows: An enlarged left ventricle, with atheromatous vessels, but without marked valvular lesion. The urine, of a specific gravity of 1022, was free from albumin and sugar. At the last visit, on May 24, the preservation of the small patch of vision upon the temporal side continued.

Remarks.—In Case 2 the diagnosis of embolism, in contradistinction to thrombosis of the artery, is not quite so clear as in the first case which was reported, but may fairly be assumed to have been the lesion on account of the absence of a previous attack of temporary blindness in the affected eye, a simultaneous attack of temporary blindness in the unaffected eye, and giddiness, faintness, or vertigo—symptoms which Priestly Smith has taught to be somewhat diagnostic of thrombosis. In addition to the curiously constricted appearance of the upper temporal vein, the interesting feature of this case resides in the map of the field of vision, and the preservation of an area upon the temporal side in which form-sense remained.

In Case 3 there is some question between embolism and thrombosis, as the patient's general condition was such that the latter lesion might readily have formed. However, the usual ophthalmoscopic signs of embolism were present, and those which have been supposed to indicate thrombosis were absent. Small hæmorrhages along the course of the vessels have been noted in embolism; indeed, in one instance recorded by Knapp (*Archives of Ophthalmology and Otology*, Vol. I) there was extensive infarctus. A hæmorrhage upon the surface of the disc is, perhaps, more uncommon.

The dark color of the inferior temporal artery, so that the hue resembled that of venous blood, probably indicated slowness of the circulation. This phenomenon has been noted by V. Jaeger, Schneller, and is referred to by Schnabel and Sachs. In Schneller's case the arteries for some time had the appearance of narrow retinal veins.

The chart of the field of vision in this case closely resembles that of the former example. In each there was an almost exactly similar patch of the temporal field, in which in the one, form-sense, and in the other, light-sense was retained. In a number of instances of embolism, presumably of the central trunk of the artery, an eccentric (temporal) patch of the visual field has remained unobliterated, moreover, in the absence of any visible cilio-retinal vessel. Fischer, who discusses this phenomenon at some length, suggests several explanations. In his own patient, a portion of the retina which surrounded the papilla like a girdle retained its sensitiveness to light, and, according to this author, owed this preservation of function to a slight blood supply from ciliary vessels through the smallest cilio-retinal branches. It is possible the same explanation is applicable to cases in which the area of retained vision (light-sense or form-sense) occupied a larger portion of the nasal retina and caused the partial preservation of the temporal field.

Another explanation, discussed by Fischer, is that the diminished flow of blood in the central vessels after embolism is less marked in the areas near the papilla than in the more remote sections of the retina. In other words, it is assumed that all portions of the retina do not suffer equally from the diminished supply of blood, and that a portion of the nasal retina in part retains its functions. In a case of so-called hæmorrhage into the optic nerve observed by Magnus, fourteen days after the sudden blindness the patient began to see to the outer side. The exterior half of the retina and the macula remained blind. Magnus considered this condition of differential diagnostic import between embolism of the central artery of the retina and hæmorrhage into the optic nerve, and on the strength of it excluded embolism. Fischer, who quotes this case, is not in accord with Magnus as to the value of this point.

In Case 3, there was no apparent difference in size of the vessels passing to the nasal and the temporal side of the retina to account for the retention of a patch of functionally active retina. In Case 2, no small transverse branch was to be seen, and no vessel passed to the temporal side of the retina. Probably, as Fischer admits, neither of the theories which have been suggested is satisfactory, and we are not in position to explain the reason why a part of the nasal retina retains, partially at least, its function. Evidently, in some manner the blood supply of this portion of the retina is not so decidedly obliterated as elsewhere, or else by a collateral circulation it receives nourishment, although in an imperfect manner.

Discussion.

Dr. Edward Jackson, Philadelphia:—As bearing upon the question of embolism or thrombosis, I have in mind a case in which the history pointed toward the latter. A young man otherwise apparently healthy, gave a clear history of repeated attacks of impairment of vision in the affected eye. These attacks had occurred for some years, at first at long intervals, then more frequently. The final attack occurred on a Sunday morning while he was reading the newspaper. He said the sensation was exactly similar to that experienced on former occasions. He stopped reading and sat for a few minutes waiting for it to pass off but the trouble did not pass off; and instead, vision rapidly grew worse until light perception was lost. I saw him twenty-two hours after the occurrence of the trouble. Light perception was then entirely lost. Œdema of the retina was very marked. The margins of the disc were obscured and the retinal veins contracted irregularly. There was no movement of the column of blood. The arteries were not materially altered in appearance. The patient subsequently remained in good health until the occurrence of an attack of typhoid fever from which he died.

As bearing upon a point in reference to Dr. Ayres' case, I have in mind a case which came to me last November with extensive hæmorrhage in the region of the macula and a second hæmorrhage in the neighborhood of the optic disc, neither causing complete loss of light perception. They had occurred without any apparent predisposing cause. The patient was inclined to ascribe the occurrence to exposure to tobacco smoke, which he never could stand. He had been in a room filled with smoke until he suffered from great nausea and discomfort, but had not vomited. He went on the street and coming to a street lamp noticed something wrong with the sight. There has been almost complete recovery with no recurrence of the hæmorrhage in six months, and the man is perfectly healthy in all respects, so far as can be judged by repeated careful examinations.

Dr. S. C. Ayers, Cincinnati:—A curious thing is that so many cases of embolism or thrombosis occur in the morning. Many patients wake up and find the eye blind. This was the case in the three instances which I have reported. I am certain that we have some cases of genuine embolism from the fact that the arteries remain permanently obliterated. In regard to the case reported, I am sure that it could not be embolism. What it was, unless thrombosis with temporary obstruction, I do not know.

"IMPURE" PARETIC DEMENTIA AND ITS FORENSIC RELATIONS.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY JAS. G. KIERNAN, M.D.,
FELLOW OF THE CHICAGO ACADEMY OF MEDICINE, LECTURER ON FORENSIC PSYCHIATRY UNION LAW SCHOOL OF CHICAGO.

Many European and some American alienists have drawn the line between insanity attacking an intact organization and attacking one already disordered by heredity or disease. What is true of insanity is also true of paretic dementia. This certainly becomes tinctured with certain features according to the organization it attacks. The organization attacked, may already be the victim of a constitutional disease like phthisis in which case the emotional exaltation of the spes phthisica becomes exaggerated with the emotional state of true paretic dementia, permeated, however, by a suspicional phase. The claim has been made that these are not paretic dementia plus the individual defect, but new types of the paretic dementia. Fournier, for example, went so far as to claim that syphilis produced a pseudo-paretic dementia. I have already shown that exceedingly valid grounds exist for refusing to admit the existence of such a type.[1] Bonnet[2] has recently has recently sustained my position in a memoir crowned by the French Medico-Psychological Association.[3]

Regis has gone even further than Fournier, for he claims that beside the type of paretic deméntia which becomes developed in its own time, and which is the true paretic dementia, there are other cases which occur unexpectedly, some time before, others after the ordinary period, which may be said to range between the ages of twenty-five and sixty-five years. The first may be designated as premature paretic dementia, the second as late paretic dementia. Cases before the age of twenty-five years, are very rare, and only a few cases are recorded coming on before the age of twenty. The premature type, unlike the ordinary type, has always a powerful etiological factor, such as heredity, syphilis, traumatism, saturnism, or general or local diathesis. These causes appear to determine in these cases an early predisposition, and prematurely to place the brain in those conditions in which it is found in mature life. Premature paretic dementia has a slower progress and a longer duration; it is more frequently subject to remissions, and is susceptible of a more or less permanent cure. To the designation premature and to the positiveness of the position here taken, I have elsewhere[4] shown that most decided objections exist. The symptoms which Regis has grouped under this title may appear at any age, and are due to the organism attacked. A careful examination which I made of the subject some years demonstrated ago to me,[5] that this was the true explanation of the facts cited by Regis in support of his position. Whatever be the etiological factor, the organism attacked tinges the paretic dementia, and not the etiological factor. The normal organization furnishes the typical paretic dement. The organism in which a neurosis has been set up by phthisis, lues, gout, rheumatism, traumatism, lead-poisoning, insolation, heredity, ataxia or other causes, furnishes atypical cases of paretic dementia presenting many features in common.

Klippell[6] claims that among the arthritics, as among other diathesitics, types of paretic dementia may occur; pure paretic dementia, paretic dementia with complicatory neuroses, and finally the pseudo-paretic dementia found in diathesitic conditions.

These atypical cases simulate those of other psychoses at various times during their progress.

Foville[7] states for example that, during the last few years, cases of paretic dementia have been noticed in which delusional states added to muscular agitation assumed alternately the form of maniacal exaltation and melancholic depression, and it has been proposed to class these as paretic dementia a double form. The chance of error that we most often meet with, is the possibility of confounding the period of excitement of circular insanity, with the beginning of the expansive period of paretic dementia. The resemblance may be very great, both as regard bodily and mental symptoms. When intellectual disorder is added to the maniacal exaltation of circular insanity, it frequently assumes the form of the grandiose delusions so frequent in paretic dements. Even when there is no delusion properly so called, the resemblance may be very great. The mind deranged with enterprises, the opinion of self in the intellectual, artistic and poetical domain, exaggerated; the optimism generalized, in a word accompanied by impulses to theft, to excesses of all kinds, to the most compromising actions, might produce the appearance in the two psychoses of almost identical characteristics. It is well known, that certain paretic dements at the onset of the excitement may not present any speech or motor disorder. On the other hand, in certain cases of circular insanity, the close connection between the emotions and the cerebral activity may impart to the speech a degree of tremulousness, very difficult to distinguish from that of paretic dementia. Finally, as Falret has shown, in a few cases of circular insanity, pupillary derangements, apoplectiform and epileptiform attacks have been noticed.

A pyschic element of great value would be the inception of dementia which is common enough at the onset of paretic dementia to be considered constant. But this is often so disguised in consequence of the general state of excitement, that it is almost impossible to ascertain its existence.

Regis[8] thinks he has found a criterion in the nature of the patient's feelings. He claims that the paretic dement is really kind-hearted, generous and even prodigal, desirous of being agreeable to everybody, and spreading around him the treasures of a common benevolence. The patient suffering from circular insanity, is wicked above everything, cantankerous, ironical and clever in injuring everybody. We are far from denying this is often so, but we have known paretic dements, who were caustic and mischievous, and patients suffering from circular insanity, who are generous and beneficient.

Gilles claims,[9] that circular paretic dementia bears the same relation to circular insanity, that exalted and depressed periods of paretic dementia do to mania an dmelancholia; circular paretic dementia is especially frequent in hereditary cases. The remissions occur with great suddenness and apparent completeness. In the depressed state intellectual and organic failure with trophic disorders occur, in the expansive period, temporary amelioration is likely to appear, eschars, congestive attacks, the menstrual period and acute diseases form the transition of one phase into another. Circular paretic dementia may appear suddenly after one or two attacks of simple insanity, or in the course of true circular insanity.

The alternating type is most frequent. The duration of the psychosis is longer than the ordinary type of paretic dementia.

How difficult the diagnosis between circular paretic dementia and circular insanity is, may be judged from one of my cases. A patient who has a strong hereditary taint, is regarded by me as a paretic dement, and by so excellent alienists as Drs. Dewey and Bannister. as a circular lunatic.

The types of paretic dementia due to lues, traumatism, insolation, phthisis, lead poisoning, heredity, etc., but particularly the hereditary types, are exceedingly likely to assume this circular character.

The rheumatic and gouty types have prolonged remissions, which may, as Spitzka, Regis and myself have observed, pass into recoveries. In my experience, the other types do not recover as Regis claims, but there is a long-lasting querulent, paralucid condition, in which the patient while retaining to a limited degree his former exalted opinion of himself conceals this under resentment evinced in lawsuits or fault finding. The exalted opinion is often the result of a delusion of memory. The same is true of the depressional delusions, which are sometimes so thus retained, as to affect business transactions. One of my patients with decided hereditary stigmata, was attacked by paretic dementia. His periods of exaltation and depression alternated twice or thrice and disappeared, leaving a paralucid querulent pessimistic state. He has an inward conviction, from what were evidently memory delusions based on this former depression, that every thing was going to go wrong with his business. Under the influence of this state he sold out some stock which, by a "bear" movement induced by a lawsuit, had been forced down in value. This law-suit and the resultant "bear" movement, had been foreseen by him when he purchased the stock. The stock rose above par within a week after he sold it. The remission gave place to a period of depression, followed by one of emotional exaltation during which he was committed to an insane hospital. Suit was brought by his conservator to annul the sale of the stock. The jury under the instructions of the court decided that the sale should stand. This decision was in full accord with repeated decisions of the Illinois and Iowa Supreme Courts, which held that persons of unsound mind are to be held bound by an executed contract or conveyance where the transaction is fair and reasonable, and in the ordinary course of business, and where the mental condition of the party is unknown to the second part, and the parties cannot be placed in status quo ante.

In another case with hereditary taint, complicated with lues, there occurred periods of paralucid querulency, emotional depression, and exaltation. The patient previous to the demonstrable onset of the paretic dementia had contracted to have two houses built. The contractor, after making several sub-contracts, failed. The sub-contractors demanded payment of the paretic for work which the contractor had been previously paid. This was refused. The patient was sent to an insane hospital, whence he was discharged in a paralucid querulent interval. Despite my advice to the contrary, he was placed in charge of his property. In a short time he verbally agreed to pay the contractors their bills. Owing to a new period of exaltation requiring hospital treatment, these promises were not fulfilled, whereupon suit was brought. The jury decided for the plaintiffs for the same reason as in the previous case.

These impure types are hence of peculiar forensic interest, since they nullify the ordinary prognosis as to the duration of remissions in paretic dementia and of the disease itself.

A prominent clinical feature of these cases is the temperature. Rottenbiller[10] has found the paretic temperature is subnormal, and that extraordinary daily variations, without apparent cause, are frequent (in one case the temperature rose from 97 F. in the morning to 102.6 F. in the evening, and fell again to 88 F. the next morning); these characteristics are present in the early stages of the disease and in remissions.

This in my experience has been almost exclusively the case with the premature paretic dements. In these, the asymmetrical axillary temperature to which I called attention[11] about a decade and a half ago is peculiarly frequent.

[11] Jour. Nerv. and Mental Disease, 1878.

Regis has sufficiently albeit too strongly covered the point of age. The luetic, gouty, rheumatic, traumatic and hereditary types occur at any age. The luetic cases resulting after the age of 65, are of rather long duration. In three such cases, the patient reached the age of 73, but each resided the whole period in an insane hospital. In three hereditary cases, occurring after 65 (one male, two females), of less duration (6 years); three sons were also afflicted at from 17 to 23 with paretic dementia. The sons died ere their parents from intercurrent complication due to trophic changes: the spinal symptoms were especially predominant. In epileptics who became paretic dements at the climacteric period the psychosis ran its usual course, and rarely lasted three years after its onset. In ataxics however, the remissions were frequent and protracted, but querulency existed.

The Hebrew race, as Spitzka[12] several years ago pointed out, seems to be peculiarly liable to this type. Heredity and lues prepare the soil which this psychosis attacks. Pure paretic dementia is, in my experience, rare with Hebrews.[13]

The forensic results of this type of paretic dementia, have already been shown. This psychosis constitutes at times no little financial danger to communities from the precipitation of panics.

DISCUSSION OF ELECTRICAL EXECUTION.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty third annual meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

BY A. D. ROCKWELL, M.D.,
OF NEW YORK.

While I do not believe that the best use to which a man can be put is to kill him, yet all will agree that if the law will kill, let it kill decently. It is evident that the sentiment against hanging and in favor of some method quicker and less repulsive is strengthening and that other methods will sooner or later replace the rope everywhere. Mr. Edison while in Paris during the exposition gave his opinion so positively in regard to the efficiency of electricity that the medical section of the French Academy of Sciences aided by Marcel Duprez, a prominent electrician, have had the matter under careful investigation. There is always opposition and friction attending changes for the better, and this change has been no exception to the general rule. The whole tendency of our civilization is, however, in the direction of humane methods in dealing with criminals and that form of execution which is quickest and least repulsive should be adopted. It is a mathematical impossibility that any human being receiving in proper form a electrical current of lethal energy should appreciate even for a fraction of a second the slightest pain. It has been ascertained that the brain is one-twenty-fifth of a second in recognizing an impression, and one-twenty-eighth of a second in telegraphing that an impression has been received, and as nerve force travels only about 100 feet a second, while the velocity of the electric current is millions of times greater than this, the brain has absolutely no time to appreciate a sense of pain. As between electricity and certain other methods of capital punishment, it is not altogether clear that the former is the best that could be suggested. The guillotine and the garote are practically instantaneous and painless in their action and attended with only a fraction of the paraphernalia and expense of the method now adopted in New York State. There is, however, an apparent brutality attending both these methods that repels, and a mutilation and shedding of blood, which public opinion in this country seems unwilling to tolerate.

The action of poison is open to none of these objections, and it seems somewhat singular that it has not more strongly commended itself to the philanthropic mind seeking simpler and more humane methods in the legal taking of human life. But as between electricity and the rope there can, it seems to me, be no question. Let us suppose that it had been customary to execute by electricity instead of by hanging, and that some one in the supposed interests of humanity should suggest that the former method be abolished, and the latter substituted; that a method practically instantaneous and painless, unattended by mutilation and without any distressing outward manifestations of pain, be replaced by one which usually fails to extinguish life for ten or twelve minutes, which in many cases it is reasonable to believe is attended with torture, and where the convulsive manifestations are horrible to witness—such a suggestion could not have the slightest claim for serious consideration, and as a matter of fact would never be offered.

After the passage by the legislature of the State of New York, of the law substituting electricity for hanging in the execution of criminals, there arose a terrible storm of opposition that apparently had for its basis extensive commercial interests. It was claimed by the opponents of the new method, that electricity was by no means certain to destroy life without the infliction of great pain, and the popular mind was agitated by repeated assertions of the possibility and probability of repulsive disfigurement by the heat and chemical action that would necessarily be developed in the use of currents of such great power. To determine these points and to advise the State as to the best methods of procedure, a commission was appointed consisting of Dr. Charles Mac Donald, Chairman of the State Commission in Lunacy, Prof. L. H. Laudy of Columbia College, and the writer, who both at the Edison Laboratory and at the various prisons of the State, experimented largely upon animals, and tested many devices and methods for the application of the current. There could be no charge of cruelty in these investigations for in no single instance was there any evidence that the slightest pain was inflicted.

The largest animals, such as horses and a bull, instantly succumbed to an electric pressure of one thousand volts, while dogs and calves were as readily destroyed by five and six hundred volts.

But one impact of the current was found necessary, for death was instantaneous in every case.

Immediate examination after the opening of the circuit invariably failed to elicit the slightest respiration or heart beat, and careful and persistent efforts at artificial respiration conducted by Dr. Fell of Buffalo with the latest and most approved appliances were without avail.

In view of the fact thus satisfactorily demonstrated that one thousand or at the most fifteen hundred volts would instantly kill any animal large or small, we very naturally inferred that any human being would succumb even more readily, but to make assurance doubly sure, it was recommended that not less than 1,500 or 2,000 volts be employed in the execution of criminals. To our great surprise therefore it was demonstrated at the first electrical execution, and confirmed in every subsequent attempt, that it was far more difficult to kill a man by electricity than any ordinary domestic animal however large. In the only execution which the writer attended, when four criminals were successively subjected to the electric stroke, the first contact of twenty seconds with a voltage of 1700 left its victim apparently lifeless with the exception of a slight fluttering of the pulse and what appeared to be a slight expiratory effort.

---

[12] Jour. of Nerv. and Mental Disease, 1880.

[13] Review of Insanity and Nervous Diseases, Vol. II.

Because of these faint evidences of vitality it was decided then, and has been customary since to repeat the shock once and sometimes twice. That the victims were, however, in every instance so thoroughly devitalized by the first shock as to preclude the possibility of resuscitation, and that every vestige of consciousness was instantly obliterated, admitted of not the shadow of a doubt. In these cases a man's brain acts in two ways, and I should say that the reasons for this increased strength of current necessary in the case of a human being were both psychical and physical. In the first place, the man knows what is coming, and every nerve and muscle is tense with involuntary resistance. There is a mysterious likeness between nervous force and electric force; not a resemblance exactly, but a something about each which science has yet to fathom.

I have no doubt that this nervous tension operates directly to impede the action of the electricity, while the secondary effect is physical. The body conducts electricity by virtue of its saline solutions.

Now fright drives the blood away from the surface to the central portions of the body.

When a man is placed in the chair he is necessarily terribly frightened, and the result is that the surface tissues are unnaturally dry, and hence inferior conductors. With an animal these influences do not prevail, but the most striking confirmation of the probable truth of this suggestion lies in the fact of the greater readiness with which life is extinguished in men from accidental contact with electrical energy.

Even where the contact has been incomplete and imperfect, linemen have been instantly killed with electrical potentials no greater than those employed in judicial executions. When a man thus accidentally comes in contact with the current, his will or nervous force is in a passive state and offers no resistance to the action of the current, while the surface of the body is usually flushed with the exertion of work, and in the highest state of conductivity. Notwithstanding the efforts of a united press to exaggerate results, no one who has once witnessed a properly conducted execution by electricity can fail to commend it as a most humane method as compared to hanging. Aside from the fact that a human life is being taken by violence, there is little in connection with the execution that is revolting to the senses. After the first convulsive movement as the current is received, every muscle is simply tense and motionless until the current is broken, when relaxation takes place and the man is to all intents dead.

It will be recollected that the press raised a great outcry against the use of electricity, not only because of its supposed inefficiency, but because of what was described as repulsive mutilation by burns and scalds. While the degree of heat generated, and the influence exerted upon the superficial tissues, varied in the different cases, according to the position of the electrodes and the density of the current near the points of contact, in no instance was there any such repulsive disfigurement as has been intimated, and in all but one or two the effects produced were so superficial and slight as to be unworthy of comment. It cannot be denied, however, that owing to the limited area through which the tremendous voltage required has to operate, and the immense resistance offered to its passage, there occurs a remarkable drop in potential and an astonishing development of heat, which without the exercise of the most intelligent and careful supervision might result in such severe burning as to bring under public condemnation a method which thus far commended itself to all eye witnesses.

But it is not voltage alone that kills, but its rate of expenditure in the body as expressed by ampères, and the time consumed in its expenditure as expressed by the volt ampère seconds indicating the measure of the heat developed during the action of the current. As stated by the distinguished electrical expert, W. J. Jenks, "none of these factors are well settled as yet in their relation to the energy actually required to cause instant and painless death. By death, I mean now not alone cessation of consciousness of a perfectly healthy human being in an interval too brief for thought to measure, and the establishment of conditions which produce gradual and final expenditure of the stored nervous energy of the brain and the subordinate centers of distribution of vital force—such as the pneumogastric nerve and the spinal cord. I mean also, total paralysis of all the vital organs, and of the nervous centers by which they are directly or indirectly vitalized, and by which the muscles of the extremities are actuated, so that when the current is broken there can be no reflex action of the muscles, such as would indicate the presence of residual life energy, or a possibility of its resuscitation."

The question which physicists must determine is how with a comparatively low voltage the same number of ampères that are expended upon the periphery and therefore in a measure lost, could be made to act exclusively on the centers of life and nervous activity, instantly devitalizing them, while leaving no outward manifestation of the terrific power employed.

It has been asserted that the subject of executions by electricity is one with which the physician should have nothing to do, and vigorous protests have been made against the propriety of allowing the subject of legal executions to be discussed in our medical societies.

In arguing that the function of the physician is to save life and not to be in any way connected with devices that destroy—it is forgotten that in one of the departments of our art, our noblest efforts are enlisted in taking, for the purpose of saving life; and when death is inevitable the physician is at hand to soften the transition from visible time to invisible eternity. When the law, therefore, decides that some new and better method be adopted in the disposition of those against whom its heaviest penalty has been decreed, who but the educated physician is to decide upon the humanity of such change, and who but he should be selected to advise the State as to the proper technical methods of procedure.

Whatever is worthy in action is proper in discussion, and as one of the advisory commission, appointed by my State, in the interests of the best methods of execution by electricity, I have felt that our work was never along more truly professional lines, or more in the interests of humanity.

ELECTRODES, AND THEIR APPLICATION IN ELECTROCUTION.

Read in [illegible] he
Forty-t [illegible]

BY GEO. E. FELL, M.D., F.R.M.S.,
OF BUFFALO, N. Y.

So long as the death penalty is regarded by the law as a necessity, so long will electrocution be the most humane method of executing it. This statement is made only after the most careful observation, extending some years over this inquiry, and after having witnessed the execution of William Kemmler and Joseph L. Tice at Auburn, N. Y. The term "humane" in this connection has a wider application than is generally considered. In the execution of the death penalty, the carrying out of the saddest mandate the law requires of its officers, the sense of *duty* has nerved them to their work. Even should they feel that the law may be overstepping its bounds in taking human life, it must be conceded that for the good of the greatest number its behests must be carried out. It should be remembered that the ends of legal justice are usually reached by slow processes; that malice is not a factor in any proper judicial decision, but justice mainly, when the decisions are reached through honest legal process. These facts should and do go a great way towards supporting the executive officer in the discharge of the most trying ordeal which an officer is called upon to perform. Humanitarian factors in the execution of the death penalty enter not only into the effect upon the culprit, in the prevention of physical or mental suffering, but also to a marked extent upon the immediate executors of the law. Electrocution when properly carried out offers the readiest, least troublesome of preparation, least horrible and most humane method of carrying out the death penalty. While the results of the application of this method have heretofore demonstrated these statements to be true, as compared with other known methods, there is yet, I believe, chance for improvement in the methods utilized, so far as the application, at least, of the electrodes is concerned.

The electrodes first suggested, in the Harold P. Brown chair, which was described in the Kemmler inquiry, consisted of a sponge adjusted upon a plate of copper to fit upon the sole of each foot of the culprit, this forming a double electrode. The other, a somewhat similar contrivance or cap, of suitable metal, placed over the skull, with a rubber cap to fit tightly to retain the moisture in connection with the sponge. No special detail of application of moisture or fluid to wet the electrodes was devised—possibly because the first chair built upon this plan (which now lies in the basement of Auburn Prison) was not considered suitable for the purpose it was intended to fulfil. The chairs in use really have fewer objectionable features than the one just mentioned, in that they conform to the ordinary shape and peculiarities of the chair commonly used.

The next arrangement, which was the Kemmler chair, provided one electrode to apply to the spine and to the upper portion of the skull, to carry out the suggestions I first made in connection with this subject, "that the apparatus to be used should be arranged to permit the current to pass through the centers of function and intelligence in the brain." (See Report of Commission to investigate and report the most humane and practical method of carrying into effect the sentence of death in capital cases, page 84.)

The last method of carrying into execution the death penalty by electricity, so far as the electrodes are concerned, was the application of a wet sponge to the thigh and the forehead of the culprit.

These three different applications of the electrodes may now be considered. It must be conceded that the objective organ, or organs, which must be influenced to produce the most rapid death, consist of the heart, the center of the circulatory, the brain and spinal cord, the centers of the nervous, systems. If this is conceded we think there should be no difficulty in arriving at the best location of the electrodes which will the most efficiently destroy the activity of these different portions of the organism. What should be taken into consideration, of course, is the extent of resistance offered by the tissues through which the current is passed, the desideratum being to apply the electrodes so as to offer a minimum of resistance together with a maximum of influence of the current upon the organs mentioned. The application of the electrodes to the soles of the feet calls for the passage of the current through the entire extent of the limbs before the vital organ, the heart, is affected by it. The application of the electrode to the thigh also presents a greater extent of tissue than is necessary, in my opinion, and in reality is not so satisfactory for other reasons. In fact both these methods prevent the greatest intensity of the current from being expended upon the heart. In other words, the conductor represented by the cross section of the whole body, cannot permit that intensity of current that would be presented were the lower electrodes applied more closely to the cardiac region. When it comes to the application of the electrodes to the head we will find that there is valid objection to the forehead electrode as used at Sing Sing, and in the case of Joseph L. Tice at Auburn. Understand, that we are endeavoring to find the best theoretical points of application of electrodes. We must admit, of course, that electrocution may be carried out successfully without placing the electrodes in theoretically the best positions. Given a sufficiently powerful electric current applied to the hands, or to any vital portion of the body, its influence is sufficiently powerful to destroy life. But what is desired is to do this in the best way from all standpoints, standpoints of convenience in application as well as of the completeness of the work with the absence of reflexes or distortions of the body, which might seem objectionable. As to the forehead electrode, it is only necessary to look at a longitudinal section of the encephalon or entire head to see that much of the current may be expended without influencing the cerebrum or the cerebellum, except through dissemination to the head as a conductor. Whereas, were the electrode applied to the top of the head, as in the Kemmler execution, there could be no question as to the course of the current. Furthermore, it is important to destroy the reflexes of the spinal cord; this would be better accomplished by the application of the head electrode to the top of the head than to the anterior portion. Then, again, I think there is no question but that the application of the electrode to the top of the head can as easily be carried out,or more easily (as in the Kemmler execution), than can the forehead electrode (strapping) method used at Sing Sing. The objection to the application of the electrode to the spine, as in the Kemmler execution, was simply that it was not so easily accomplished as probably, to the thigh; yet theoretically the location was the more desirable.

A still more desirable location, however, both theoretically, or from the physiological standpoint, and also from the standpoint of results in experiments upon lower animals (in which it has been demonstrated that the nearer the electrode is placed to the heart, the more suddenly its action is made to cease), would be the application to the abdomen, in the epigastric region. (See Dr. Tatum's experiments in my report on the "Influence of Electricity on Protoplasm," President's Address before the American Microscopical Society,in this city,August, 1890.) The size of the electrode (within reasonable bounds; it should be, of course, quite large, say 16 to 24 square inches of surface), would probably have very little effect upon the results. The object, however, it seems to me, is that the full intensity of the current be applied to the cardiac region, the force being then expended directly upon the heart before great dissemination of the current is produced by the great cross section of the body in this region. By none of the means heretofore used would it be possible so markedly to influence the heart by the passage of the electric current. The abdominal application, also,could be more readily accomplished. The electrode could be applied before the culprit left the cell, by a strap around the body, the electric connection being made after he was placed in the chair, and the saturating of the electrodes carried out by the same irrigating measures (fountain syringe) used at Auburn at the Tice electrocution. We think there is no question that that result would be more satisfactory, if it were possible to have anything more satisfactory than the execution that took place when Tice was suddenly ushered into eternity at Auburn.

I cannot close this article without referring to the unjust, impracticable and unreasonable statements urged by the opponents of electro-execution; and I have a very great degree of satisfaction, after witnessing the humane taking-off of Tice and Kemmler, in that I have been a strong advocate of a method which so effectually takes away from the execution of the death penalty so many of the terrors that formerly characterized it. I again most emphatically repeat, "that it can be truthfully stated that electro-execution, inspired in the interests of humanity, and with the methods employed, has demonstrated the truthfulness of all that has been claimed by its advocates. If criminals must be executed, there is no method so certain and ready of applicability, if the apparatus is properly provided." (See Proceedings of the American Microscopical Society, August, 1890.)

Discussion.

Dr. Robert Newman, New York City:—The subject dwelt upon in the papers of Drs. Rockwell and Fell with regard to electrocution, is one of the most important that can command the attention of the medical profession, as well as every humanitarian. I do not think these two papers should go by unnoticed. They should be thoroughly discussed and widely read when published. I move, therefore, that this Section ask the Committee on Publication for an extra supply of copies of these two papers, to be distributed largely over the whole world. If they are published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, they will have a limited number of readers.

I shall never forget, when Kemmler was executed, how the press maligned electricians and said electrocution was a failure. At the time I was in Berlin. These ideas ought to be dispelled. I do not know of anything that has been more maligned than electricity, both by the ignorant and by malicious persons; consequently we ought to do something to dispel erroneous ideas and tell the truth. If electricity has been maligned, electrocution has been much more so, particularly in Germany, and by men who ought to know better. If several thousand copies of these two papers were sent to editors all over the world, it would be the practical thing to dispose of this matter.

This idea of feeling pain during electrocution cannot be too soon dispelled from the public mind generally. The sooner it is done the better it will be for science and humanity.

Dr. George E. Fell, Buffalo, N. Y.:—Regarding Dr. Rockwell's reference to the electric current being much more rapid than the nerve current, I will say that this subject was brought up in the National Electric Light Association at Niagara Falls in 1889. Professor Anthony urged that we could not claim that the question of velocity of the electric current would settle the point as to whether death by electricity "would be painless or not." The electrical executions appear to have settled it conclusively and to uphold the generally accepted belief that the speed of the electric current through a living human organism is very many times faster than the nerve current, which has been estimated by Helmholtz to be about 111 feet per second.

One of the most interesting features in connection with electrocution is this, if a post-mortem be made shortly after you find that a great portion of the blood in the muscular tissue is forced into the visceræ of the body. The kidneys, liver, lungs and spleen and brain are remarkably congested. On cutting into the muscular tissues post-mortem we find that very little blood will flow. This instantaneous tonic contraction of the muscles and almost immediate excessive congestion of the viscera is in itself enough to produce death. The Kemmler execution, which was so horribly mutilated by the press of the country, was just as good as the Tice execution, except the current was kept on longer than was needed.

Regarding the question of linemen being instantly killed, I have often-times questioned whether that is so. A man in Buffalo caught both electrodes of a dynamo and was said to have been killed instantly, but it was found on enquiry that he breathed a little afterwards. The Tice electrocution occupied 45½ seconds from the time the current was turned on until the execution was over. I believe in all instances in making and breaking the current even if it be an alternating one. The effect on the body is much more marked by thus doing than by the continuous current, unless of very high voltage. A current of five or ten seconds will not produce heat enough to amount to anything. and I believe if the current is made and broken at intervals of from three to not more than five seconds the time of execution can be cut down one-half less than the Tice case.

Dr. A. D. Rockwell, New York City:—Mr. Chairman: I have very little to say in addition to what I have already said in my paper. Theoretically, perhaps, the position of the electrodes as suggested by Dr. Fell may seem correct, but practically I believe the method as adopted to be preferable. In the second series of executions, one electrode was placed on the forehead, and the other on the calf of the leg.

In the Kemmler case, one electrode was placed at the small of the back where it is difficult to obtain a perfect adaptation, and where the conduction is by no means all that can be desired. With the application of the electrode in such a place, I ascribe in a measure the somewhat unsatisfactory result of this first test of the efficiency of electricity in judicial executions. Kemmler himself was aware of the imperfect contact and voluntarily pushed himself back upon the electrode.

We want, of course, to get as near as possible to the centers of vital force, but with the better knowledge that experience has given, it does not seem to me that it will make much difference where the electrodes are placed. Taking into consideration the possibilities suggested in my paper, of expending the force of the electric current on the central nervous system rather than upon the skin, thus avoiding the danger of burning, against which such an outcry is made, currents of greatly increased voltage can be used. With such tremendous pressure complete devitalization would take place, so that there would remain absolutely no residual life energy.

ON THE REFLEX THEORY IN NERVOUS DISEASE.

Read in the Section of Neurology and Medical Jurisprudence at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY L. BREMER, M.D.,

OF ST. LOUIS, MO.

The subdivision of practical medicine into a great number of specialties has not proved an unmixed boon to either science or the welfare of humanity. If one peruses the reports of the specialists and becomes familiar with the trend of their work, one is struck with the peculiar antagonism that exists among the respective representatives or followers of the several special branches. The chief interest of their reports generally centers in the observation that by successfully treating a disease of the organ to which *they* pay special attention, symptoms in distant organs which other specialists claim as their domain, have vanished; the additional remark being generally made that the patient had been treated by such and such a specialist of another order without any benefit.

A few such results, misconceived as a rule, as to their true nature and import, will render the young specialist enthusiastic; from an enthusiastic he is apt to develop into a fanatic, who builds dogmas on misunderstood facts.

One of the chief causes of these aberrations from the true intents and purposes of practical medicine is to be found in the erroneous conception and interpretation of reflex action in disease.

Ever since the custom became prevalent among physicians, especially those practicing specialties, to look upon localized lesions as the causes of disorder in distant organs, the theory of the reflex origin of disease took a firm hold of the professional mind, to the benefit of our science and patients in many, to the detriment of both in many more, instances.

By misuse of the term, and its misapplication to practice evil results have in the course of time by far out-classed the positive good it might have wrought within proper and legitimate boundaries.

The introduction of the term "Reflex" in medicine dates back to the works of Descartes who first applied it to the involuntary closing of the lids which takes place when an object is approached to the eye. The doctrine of the reflex was later on enlarged and elaborated by Marshall Hall, Grainger, Johannes, Mueller, et al. The essence of this law is, as is well known, the response by muscular contraction of certain parts on the application of a stimulus to certain sensory or sensorial nerves. The irritation, then, is reflected as a *movement in a corresponding muscular area*, and motion is essential as a result of indirect stimulation.

The physiological experiment gave a clew to the understanding of many formerly inexplainable morbid phenomena; spasmodic affections and other motor disturbances could be traced to certain local irritations and were in many instances relieved or cured after such local troubles had been remedied.

But when the profession split up into specialties which subsequently spread and developed to present proportions, the theory of reflex action in disease was soon called to aid in the explanation of morbid conditions, which had absolutely nothing to do with that law.

The fact was lost to sight that a true reflex presupposes a *reflex arc* composed of an *afferent* nerve, a *central* nerve cell, and an *efferent* nerve. By ignoring the proper definition of reflex action great confusion was created by mixing up "Associated Sensations" or what I would like to call for brevity's sake "Co-sensation" (Mitempfindung) with reflexes. Thus quite a voluminous literature of "Reflex Neuroses" sprang up, treating of local or general, sensory or sensorial, even mental affections, caused, as alleged, by local maladies.

This mistake has had a peculiarly disastrous effect on gynecology. Five years ago I read an article on this subject before the St. Louis Medical Society, published in the *Weekly Medical Review*, 1887, p. 8 fl., under the head "Gynecology in Neuroses and Psychoses."

The remarks on this matter, made at that time, were based upon observations in private and hospital practice (St. Vincent's Institution for the Insane, St. Louis). Abridged and slightly modified they are about as follows:

Without denying the possibility of nervous and even mental derangement arising in women from comparatively trivial diseased conditions of the general organs, such as catarrh, cervical laceration or stenosis, uterine displacements or ovarian disorder, I agree with those who believe that the frequency of such cases are vastly overestimated, and that the prevailing practice of treating slight local affections with a view of bettering or curing such morbid conditions as hysteria, neurasthenia and allied diseases of the nervous system, are generally nugatory and injurious.

These injurious results of local treatment consist in aggravating the nervous symptoms. and creating a state of chronic invalidism, the prevailing condition among the women of the better classes in our days, the cures, if they do take place, being generally ascribable to other factors, principally suggestion. In many instances such alleged cures are apparent rather than real. There are women who claim that they are benefited by every local application and frequent the physician's consulting room year in and year out.

Gynecological treatment has a corrupting and debasing influence on some neuropathic and psychopathic females who develop a craving for local appliances and manipulations, a speculo-mania so to speak, frittering away their time in the doctor's office, which they have not to spare, and which they ought to devote to their homes and children. From this neglect of the household duties, domestic infelicity and subsequent divorces are apt to result. The remote causes of the latter are in not a few instances traceable to the gynecological chair. A woman who meets with disappointment in married life is now-a-days inclined to seek relief in the gynecologist's office, as she would formerly apply under like conditions to her spiritual adviser. All her thinking becomes concentrated on her womb, her egotism (generally hysterical) assumes immense proportions, she poses as a martyr to imaginary or quasi-imaginary disease, and in the worst cases worships her doctor as her hero and benefactor.

Meanwhile, the continued doctor's bills are far from having a soothing influence on the mind of the disgusted husband who sees through this farce and conceives an inextinguishable loathing for his wife. The finale of the drama is enacted in the courts under the designation of cruelty, neglect and incompatibility of temper.

Another significant fact is, that married female morphinists are almost invariably patrons of the gynecologist's office at one time or another in their career, and that they are willing to, and often do undergo, all kinds of surgical operations on the womb and its appendages, operations which generally, to say the least, are superfluous. This craving for surgical interference about the genital sphere, sometimes painful and dangerous in character, may seem incomprehensible and even incredible to some, but it is a fact familiar to those who have had opportunities to observe or treat this class of drug victims. The medical history of such patients generally contains a passage which runs like this: The operation was successfully performed and the local trouble is cured, *only* "a little nervousness," in the language of the operator, remains. This small amount of persisting nervousness was, however, sufficient to land the patient at some sanitarium.

Specially harmful and uncompromisingly to be condemned are gynecological examinations and treatment for minor ailments in young unmarried women who, following the fashion of the day, and having their heads full of misunderstood physiological notions, apply to the doctor for local treatment, or still worse, are persuaded into it against their will by weak-minded and fanatical women whose special object in life seems to be to hunt up victims for "local treatment," as it is termed *par excellence*.

Without hesitation, I go the length of saying that gynecological treatment under such circumstances is a crime, that its effects upon the mind of the young woman is that of defloration. Her moral tone, her manner of judging things is altered and lowered; with the consciousness of there being even a shadow of a flaw on her virginity, those subtle qualities disappear which constitute the charm of girlish innocence; her mind is polluted, she is unfit for marriage. and all this, because her doctor happens to hold the opinion that by manipulating the uterus he can cure neuroses. It is the bounden duty of the rightly thinking physician to shame such patients out of gynecological treatment and to help, by so doing, to restore them to health, reason and decency.

But the greatest mistake founded on the reflex delusion, and a very prevalent one at that, is gynecology in mental diseases. Having been connected with an institution for the insane for a number of years, I have had ample opportunity of watching the results of such uterine manipulations. There is scarcely a female between twenty and forty-five admitted to the asylum that has not been treated for womb diseases as the probable cause of insanity, and in case this has not been done, the attack coming on too suddenly, the suggestion is made by the friends or relatives that womb disorder is probably at the bottom of the mental trouble. Somehow it is a consoling thought to relatives of insane women to shift the blame from the brain to the womb and ovaries, especially where the cloud of heredity hangs over the family, and the doctor who pronounces the case "mere nervousness" dependent on womb disease is pretty sure, for a time at least, to meet with approval on the part of the female members of the family, and in case the patient, after a protracted local treatment is committed to the insane asylum, everybody is satisfied that everything that could be done, has been done, whereas in reality everything was done to intensify the trouble and render a cure, if not impossible, at all events highly improbable. It is a maxim in psychiatry, even more so than in general medicine, that the more recent a case presenting itself for treatment, especially institution treatment, the better the chances of recovery. These chances are impaired and sometimes destroyed by the worse than useless gynecological procedures. I say worse than useless, because in many instances they do positive harm. In the predisposed they precipitate the mental cataclysm, they kindle the flame of insanity that was slumbering beneath the embers, they confirm and fix morbid thoughts in grooves that cannot be smoothed out and turn them into channels that refuse to be dammed up.

I know of patients who were thus treated for apparently curable melancholia at home until mania supervened, and others whose delusions were fostered and deepened by local treatment; syphilophobia, imagined pregnancy or fancied destruction of the womb being the result. Frequently the doctor's personality enters into the delusion of such cases, an occurrence which gives rise to very annoying, unpleasant and easily misinterpreted situations.

In the same article I alluded to the unscientific and barbarous practice of spaying women for nervous disorders, having apparently their starting point in the ovaries.

Much had been said and written on this topic before I read that article, and much has been said and written against the practice since by neurologists. Although there has been a healthy reaction in some quarters owing to the greater spread among physicians of neurological knowledge, the evil is, I believe, even greater to-day than it was five years ago. While at the medical centers the truth has at last dawned upon those who specially treat women's diseases, and while it has been solemnly stated that women have other organs than wombs and ovaries that may be at fault and need looking after, and whilst there is a laudable attempt in those quarters to *unlearn* certain things in gynecology, as it has been put, the seed of the evil has been sown too long and too thickly as to be hampered in its spread and growth by some isolated anathemata that may occasionally be hurled against the abuse by a few authorities. Too ma[illegible] useless gynecological operations have been [illegible]nessed and admired by the present generation [illegible] physicians, and their minds have been too powerf[illegible] impressed *ex-cathedra*, for more than two decades, with the alleged beneficial results of gynecological procedures, to make room for the hope of any amelioration in the near future. The mind of the general practitioner is chronically infected with the delusions taught for years by books and in the colleges, and the speculo-mania among women prevails epidemically, having spread from the cities, its former exclusive seat, to the country population. It is a hopeful sign, however, that advanced and enlightened gynecologists are of late moving in the right direction.

What has been said of gynecological practice as being to a very considerable extent based on delusions, holds also true, though not nearly to the same extent, in the specialty of genito-urinary diseases in men. The well-known chains of nervous symptoms attending diseases of the bladder, prostate and kidneys in neurotic men have also, in many quarters, given rise to the idea that such local conditions caused the nervous disorders reflexly. Aside from the fact that at best only motor disturbances, such as spasms of voluntary and involuntary muscles (vessels, intestines) could be called reflex, many of the nervous manifestations are co-sensory, whilst the most of them (at any rate their persistance) are the result, but not the cause of them.

Mistaken notions about the reflex action have in this particular field of medicine, too, wrought an immense amount of harm, and the modern nuisance of illegitimate orificial surgery is one of the parasitic growths that luxuriates on, and at the expense of, legitimate genito-urinary surgery.

The irritable bladder, the irritable urethra, prostate, rectum, or perineum with distant associated nerve complication, affections which do not call for operative interference, any more than the irritable breast or the irritable heart, have all more or less unnecessarily been tampered with from ignorance of the fundamental teachings of neurology. Causes of functional central and coarse systemic nerve-disease (tabes e.g.) that were locally treated as vesical or rectal affections, abound in the personal recollection of neurologists, and all these improper practices were done on the reflex theory.

Another phase in the evolution of the theory of, and practice on, the law of reflex action, illustrating the blending of reality and imagination, truth and fiction, is the relation of ocular defects with certain neuroses. Since it became known that visual abnormalities often accompanied nervous diseases, oculists tried to establish a causal connection between eye-affections and neuroses, the same as gynecologists, aurists, rhinologists, dentists, etc., did before. The reflex theory gained here a new field for application.

The startling statements of the remarkable results obtained in the treatment of chorea, epilepsy and hystero-epilepsy and neuroses in general by the mere correction of ocular defects called forth the famous inquiry of the Steven's Commission. The investigation ended, as might have been foreseen, like a regular doctor's quarrel, or a theologian's dispute, each side being more confirmed than ever in the correctness of their respective positions. In perusing the history of this "Stevens' Commission" there is one point that strikes one more forcibly than any other: the patience and perseverance of both patient and oculist. Month after month elapsed without any material benefit being appreciable in the patient's condition, and yet they continued to present themselves with a regularity and endurance worthy of a better cause. The tenacity of such confiding sufferers finds its amalogon only in gynecological patients and in persons afflicted with chronic catarrh of the middle ear, who are specially hopeful and continue treatment to the last.

As with the latter classes the enthusiastic physician who treats them is in the enviable and impregnable position of the Indian medicine-man who prophesies rain until it finally does rain. The remissions and intermissions in all functional nervous diseases, and for that matter, those due to organic trouble; also, are powerful allies of the doctor who has the knack of holding nervous cases by performing small and insignificent operations on them, however indifferent they may be.

There is an old and undisputed maxim: "The world wants to see performers." This is especially the case in the neurotic world. Nothing, however, produces such an overwhelming and occasionally such a beneficial effect on the fertile, though morbid imagination of the sufferer from nervous disease, as an instrument of precision and its application. The nerve crank will swear by the oculist's "Phorometer" as he will testify to the wonderful effects of magnetic water. He will continue to have his eyes' muscles clipped by the oculistic impostor and marvel at the great advances which have been made in medicine.

I know of cases of incipient insanity that were treated by such muscle-clipping; it is needless to say with what result.

Certainly the aid of scientific and conscientious ophthalmologists to neurology and to internal medicine generally has been of the greatest advantage, and has established many valuable points touching the relation between eye and brain, and this knowledge has benefited many sufferers who, without this aid, would have continued in chronic martyrdom. I myself bear cheerful testimony to the prompt relief of some functional nerve disturbances following the use of properly selected glasses and other rationally directed ophthalmological treatment; my protest is aimed at the ocular "reflex" humbug that started in New York and bids fair to imbue the profession with the same erroneous and harmful ideas as have obtained in other specialties.

A great stir in the medical world was created when Hack announced in 1882, that he had cured a great number and variety of neuroses by cauterizing diseased portions of the nasal mucous membrane, removing small polyps and relieving catarrhal conditions generally. The firmness and precision of his reports gave a great impetus to the study and treatment of nervous affections having their supposed origin in diseased conditions of the upper air-passages. More and more the nose, throat and larynx were inspected, for the *causa nocens* in nerve diseases, and soon there was a galaxy of brilliant reports adorning laryngological literature, dazzling and perplexing the unsophisticated observer.

In Hack's report, and still more in those of his followers real reflex affections, such as asthma, continued sneezing, spasms of the glottis, and coughing, were again mixed up with associated neuroses, neuralgias and headaches, *e. g.* After the enthusiasm has subsided a little, and especially after the electric search-light of neurological inquiry had been turned on a number of these marvelous cures, it became evident that many of the successes were only temporary and that spastic seizures and sensory disturbances would return after shorter or longer abeyance, in spite of the removal of the local affections.

Like in other therapeutical booms, together with the unavoidable reaction, cases are now being reported where grave and permanent neuroses have resulted from cautery of the upper air-passages, and truly progressive specialists have begun to realize that back of the local disease there is often a central neurosis which refuses to be favorably influenced by local treatment, but yields, together with the peripheral disease, to a rational general plan of treatment. There are, however, too many left yet who believe that catarrh is the root of nearly all human evils, who imagine that nearly all morbid nervous conditions are caused reflexly from the nose, and who even believe that they can cure hysteria and insanity by local means.

While it is perfectly right and proper and simply a matter of course, to eliminate any peripheral irritations which naturally tend to intensify existing nervous derangements, it must be remembered that back of the unimportant peripheral, there is an all-important central disorder and that local means are of no avail when central ones are overlooked.

It would be needless to dilate upon the mis- and abuses of the reflex theory in aural, dental and other local diseases. Here, as elsewhere, reflex troubles are met with, but not to the same degree as is claimed by many. Some dentists especially do a great deal of damage to patients afflicted with facial neuralgia because they labor under the mistaken idea that all such affections start from the teeth. By the jarring attending operations on teeth, they often aggravate the trouble. The pulling of sound teeth for the relief of pain, a procedure which even in our days is not unfrequently resorted to, cannot be too strongly and unqualifiedly condemned.

I cannot refrain from devoting a few words to another delusion which has taken a firm hold upon the profession and which relates to the rôle that an abnormal condition of the prepuce and clitoris is believed to play in certain nervous affections of children.

Reflex epilepsies and reflex paralyses have been indiscriminately and recklessly attributed to such abnormal, often excessively trivial conditions. The reports of the speedy relief, and cure of seemingly hopeless maladies in children published in the beginning of the seventies read like tales of 1001 nights. A simple operation on the preputium or the clitoris, especially circumcision in boys and the removal of a ring of hard and inspissated smegma from the fossa glandis penis was said to have changed cripples into healthy individuals.

While I was perusing these reports one peculiarly struck me very forcibly; it was the absence of neurological criticism and the prevalence of letters written by exulting mothers who bore testimony to the wonderful change wrought by the operation, but who in their writings displayed an unmistakable hysterical temperament. What this means, both as to the reliability of such testimony and the character of the disease in their offspring I need not dwell upon [illegible] this time and place. Of late the miraculous reports have not been so frequent, although the delusion is still prevalent, that nervous disorders are caused instead of simply aggravated by perputial or clitoridian abnormalities. Again, in order not to be misunderstood, I emphasize that peripheral disease here, as elsewhere, ought to be treated, because in a certain percentage of cases (not in all, by any means!) they give rise to co-sensory and reflex disorders, possibly even reflex paralysis; I protest only against indiscriminate and senseless generalization.

The most remarkable cases of this class were the paralyses reported as cured. To my mind they were cases of poliomyelitis chronica infantum, which, while improved by relieving local irritative lesions, were certainly not completely restored.

That cases of reflex paralyses do occur, there can be no manner of doubt. Instances of this kind have been reported in the medical history of the War of the Rebellion and have likewise been observed during the Franco-Prussian War. Thus, *e.g.*, if a person, as one report has it, receives a bullet in the region of the tenth rib, and the arm on the same side is immediately paralyzed, the course of the ball precluding all possibility of an injury to the nervous apparatus of the arm either peripheral or central, we must admit that this is a true reflex paralysis.

Such cases have been almost invariably observed in sudden and violent injuries; whereas the paralyses alleged to be due to distant lesions of a chronic nature must, in my opinion, be regarded with suspicion.

The same is true of the reported reflex atrophies, whether resulting from acute or chronic distant lesions.

Our several paths in life are divergent; with the divergence in direction there is necessarily connected a difference in the facts gathered on the several fields of observation; from this difference there ensues a discrepancy of opinions and their inevitable clashing. It is by such antagonism, and in particular by our intra-professional strifes and combats that truth is finally evolved and errors disappear.

It might appear that the foregoing remarks are but an example of the well-known *orationes pro domo*, so common in specialistic literature, and that they are no more or less than one of the often witnessed efforts of a specialist emphasizing the importance of that branch of medicine which forms the subject of his predilection.

Far from it! The object of my criticisms was to bear testimony to the harmful and noxious feature of specialism, as tending by its luxuriant growth to overshadow, obscure, and dwarf "internal medicine," so-called, *i.e.*, that science which alone is capable of rendering the specialist fit for his work, and insuring that success which is not gauged by the amount of money he makes (often unearned and undeserved), but by the real and substantial aid which he bestows upon his fellow men. Of all the branches of internal medicine, however, which specialists ought to cultivate, and a satisfactory knowledge of which alone can prevent self-deception on the part of the physician and unjustifiable meddling harmful to the patient, neurology stands foremost.

REFLEX URETHRAL AND GENITAL NEUROSES, URETHRAL NEURALGIA AND HYPERÆSTHESIA AND NEURALGIA OF THE TESTES.

Read before the Section of Neurology and Medical Jurisprudenc[illegible] the Forty third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY G. FRANK LYDSTON, M.D.,

OF CHICAGO.

There are a few morbid conditions of a functional character which, although often times an integral part of organic diseases of the organs which it is my especial province to consider, are occasionally either morbid entities or else the prominent source of complaint on the part of the patient—indeed we are apt to be more often consulted regarding these functional or nervous derangements than the diseases upon which they frequently depend.

There is, perhaps, no subject in the whole range of genito-urinary disturbances, of greater importance than the varied phenomena involving nervous derangements, that are due, directly or indirectly, to pathological conditions of the various portions of the urethral canal. It is certain also, that in no class of cases which come under the observation of the genito-urinary surgeon, is an accurate diagnosis of greater importance, or more difficult to accomplish. I feel, therefore, that a contribution to the special study and treatment of such cases is to say the least, warrantable.

When we consider the vast amount of labor and talent that have been devoted to the study of the reflex neuroses of the female, due wholly or in part to pathological entities affecting the uterus and its appendages, it is certainly surprising that more attention has not been given to analogous conditions in the male, due to disturbances of the generative organs and especially of the urethra.

Taking as our point of departure the prostate body, we will find quite a close similarity between some of its morbid conditions and those affecting the uterus. Physiologically, the prostate, or at least a portion of it, is the homologue of the uterus, there being the closest resemblance in the muscular structure of the two bodies. If the muscular tissue becomes perverted in growth, we have in the one, uterine myoma, and in the other, prostatic hypertrophy, the structure of the two morbid processes being strikingly similar. When, as is occasionally the case, the "third lobe" of the prostate becomes so circumscribed as to form a distinct tumor, it is generally not unlike a pedunculated fibroid. It will be found also that certain remedies which have a pronounced action upon unstriated muscular fibre, have a somewhat similar action upon the prostate and uterus, this being especially true of secale, ustilago maidis, and hammamelis. Certain sedative remedies act very similarly upon irritative affections of the uterus or ovaries, and the prostate. To carry the argument a little further and directly approach the subject of neuroses, it will be found that certain irritations affecting the prostate, will produce effects quite like those produced by utero-ovarian irritation in women. False spermatorrhœa (spermatophobia), pseudo-impotency involving disgust for the sexual act, melancholia, hypochondria, neuralgias whether of the contiguous or remote nervous filaments, and nervous inhibition amounting to almost complete paresis, are all possible results of urethral or prostatic irritation, and these conditions are all represented by similar disturbances, such as hysteria and allied conditions in the female, due to morbid conditions of the generative organs. The analogy between the results of prostatic catarrh and those of cervical catarrh, as shown in one of the cases herewith reported, is sometimes especially striking.

One of the interesting features of stricture of the urethra, is the ensemble of symptoms of a nervous character that is so often seen, and which neuroses are frequently entirely disproportionate to the degree of organic trouble present. Cephalalgia, neuralgia in various localities, particularly sciatica, lumbar and intercostal neuralgia, are quite common, but are probably regarded by both physician and patient, as coincidences rather than as bearing any consequential relation to the stricture. Associated with these are others (quite as prominent in some cases) of a purely mental character, such as melancholia, hypochondria, disturbed sleep, incapacity for intellectual effort, and deterioration of business capacity, perhaps associated with great irritability of temper. Disturbed digestion and general faulty nutrition are quite constant. That these various morbid conditions depend upon the stricture is never fully appreciated until that organic entity is cured, when the complete restoration to health demonstrates their true relation to the primary source of irritation. Many of my patients tell me that they had become so accustomed to their little ailments that they had come to consider them a matter of course, and had never dreamed of their association with the stricture until the latter was cured. One of my patients remarked that he did not know how sick he was until he had been cured of his stricture.

Certain cases of gleet are associated with considerable mental depression which is commonly attributed to the moral effect of the supposed drain upon the system. This mental disturbance I believe to be in many instances the result of reflex irritation through the sympathetic system, which is so closely associated with the functions and nutrition of their sexual organs.

Morbid conditions of the urethra not only cause reflex neuroses in other portions of the body, but they are often a reflex result of disease of contiguous strictures; thus I have noted cases of spasmodic stricture dependent upon hernia and varicocele. Dr. Otis has described some very interesting cases of chronic spasmodic stricture of reflex origin. Operations about the arms are very often followed by spasmodic stricture and urinary retention. Morbid conditions of the anterior portions of the urethra often cause reflex disturbances of the deeper portion of the canal, or indeed, of the bladder. This is very familiar in connection with the results of contraction of the meatus.

One of the most annoying complaints which the surgeon is called upon to treat in connection with the genito-urinary apparatus, and especially in stricture, is neuralgia and hyperæsthesia of the urethra. This disorder is most often the result of long standing urethral inflammation, or stricture with its attendant gleet, and frequently persists long after all organic disease has apparently been cured. The majority of patients who suffer from urethral neurosis of this kind are either of an emotional, highly sensitive nervous organization, often simulating "hysteria in the male," or of a gouty temperament, with highly acid and concentrated urine. Anæmic and cachectic patients are especially liable to it if nervous or rheumatic. In such patients the imagination has been overwrought by the dread of serious results from urethral disease, and the mind depressed by a sense of self-degradation. The condition of the mind as well as that of the urethra, has been impaired by long continued treatment of something which, although trifling in itself perhaps, is to the patient a terrible morbid entity, and a mental incubus from which he is never free excepting during the hours of sleep. Quack literature, irritating injections, over-enthusiastic treatment, sexual starvation and excitement without gratification, are all disturbing elements in his case, and if we superadd the results of dissipation, intemperance and dietetic errors, what wonder is there that he never gets well, or that he magnifies the slightest unusual sensation about his sexual organs into something new, serious and startling. Such patients will say to us when we try to convince them that their gonorrhœa, gleet or stricture is practically well: "But, doctor, I am not quite right, I have a funny feeling at this point in the canal;" or the complaint will be varied by a description of severe burning or cutting pains in the canal during micturition, or a tender spot, usually near the meatus; sometimes the pain radiates to other portions of the sexual organs. On examination with the urethroscope, nothing appears which would account for the trouble: and treatment is usually of little avail, unless we succeed in obtaining the patient's confidence and inducing him to believe that his trouble is not organic and will soon wear away—only too often, however, he goes from surgeon to surgeon in the vain endeavor to find relief, until, despairing and disgusted, he resigns himself to what he considers inevitable fate, and lapses into confirmed melancholy and hypochondria.

Morbid states of the prostatic anus and vesical neck, with or without coexisting stricture, occasionally give rise to urethral neuralgia; great irritability of mind alternating with depression and melancholia. Vesical calculus and tumors are especially liable to be complicated by it. Hyperæsthesia of the urethra is so often associated with stricture and gleet, that it is worthy of consideration in every case in which obstructive spasm occurs during instrumentation; some canals will be found to be so hyperæsthetic that a chronic spasmodic condition exists. In some cases of chronic spasmodic stricture or urethrismus, local lesions of the mucous membrane exist, while in others nothing abnormal is to be detected.

Hyperæsthesia of the Testicle is an interesting condition which sometimes results from reflex irritation from stricture; more often, however, it is due to excessive sexual indulgence, or the opposite extreme, *i. e.*, ungratified or prolonged sexual desire. It is most apt to be associated with cachexia, gout, neurasthenia or anæmia. The testicle may be relaxed and soft, or full and firm to the feel. Oftentimes varicocele is present and acts as an efficient cause for the affection. Hypochondria, melancholia and various mental perversions of a delusional character are not unusual, and may perhaps be associated with a sluggish portal circulation or dyspepsia. Sudden deprivation of customary sexual indulgence is said by Curling to be a frequent cause. The symptoms consist in extreme sensibility and tenderness, either of the entire testicle or some spot upon its surface. So exquisitely tender is it that oftentimes the contact of the clothing and the various bodily movements cannot be borne.

Neuralgia of the Testicle is really an exaggeration of hyperæsthesia, and has in addition to hypersensitiveness, paroxysms of shooting, cutting pain in the organ. The causes are much the same as for hyperæsthesia, syphilis, gout and neuralgia having a prominent place in its etiology. Urethral stricture quite often, and prostatic and bladder disorders occasionally, cause it. The pain is much like that of renal colic, and is sometimes attended by retraction of the testis from spasm of the cremaster, and the sick, faint feeling and cold perspiration characteristic of shock. I believe that some cases are really due to irritation of the renal pelvis and ureter by sharp crystals in the urine, and this acting reflexly produces pain in the testis. Usually only one testis is involved. As a rule, the patient can walk about, but in the severe cases he is apt to be greatly prostrated, and in addition, he usually suffers from pain and soreness on movement.

The Treatment of the neuroses which have been presented consists in following some very plain indications, as well as putting in practice numerous general principles. First and most important of all is attention to the patient's mental condition. His mind should be diverted from his physical ills, and at the same time kept free from all sources of sexual disquiet. Questionable literature and the society of loose women must be avoided; in short. an attempt should be made to correct the impression so prevalent among men, that man's chief mission upon earth is the procurement of material wherewith to cloy his sexual appetite. *Once dispel the idea that his penis and testes constitute the axis around which his earthly existence revolves, and one will have done more for his patient than if he had fed him the entire contents of a drug store.* Having allayed sexual disturbance of a purely mental or moral character, it remains for us to secure for our patient physical sexual rest, it being sometimes a matter of nice judgment to determine whether moderation or strict continence is best for the patient's welfare. In a general way it may be said that those neuroses which are dependent upon or complicated by actual inflammation, acute or chronic, demand absolute continence, while in those of a purely nervous character, moderation is to be advised. It is always a hard matter to determine the degree of success of our prescription in this matter, as the patient's penis is not only quite liable to gain the mastery over his reason and judgment, but over his morals as well, and he will therefore be apt to consider that a lie to his doctor, like Rip Van Winkle's drink, doesn't count.

Second only to sexual rest, is the correction of urinary acidity. This may be corrected by diet and remedies combined, the diet being by far the most important. The proper standard for a suitable diet is bread and milk, but this may be varied within narrow limits. Nitrogenized food, stimulants and tobacco must be strictly prohibited. As an adjuvant to this regimen, the Turkish bath does excellent service.

The best remedies to correct hyper-acidity of the urine, are the acetate and citrate of potassium, liquor potass, and in gouty or rheumatic patients (who are especially liable to neurotic symptoms from urinary disturbances) lithia, colcicum, and salicylic acid. Mineral waters are very useful, the Buffalo Lithia and Waukesha waters being especially useful. Several of my patients claim great benefit from partaking freely of the Garfield Park mineral waters.

Sedatives and anti-spasmodics are often useful in these cases, the following being of service in different cases, viz.: potassium bromide, gelsemium, hyoscyamus, camphor monobromate, *morphia*, salixnigra, and ergot. Tonics are often required, the best being the chloride of iron, strychnine, arsenic and quinine. In those rare cases of spasmodic stricture of malarial origin, quinine is of course a specific. Three very useful drugs are the phosphide and bromide of zinc, and the bromide of arsenic, these being great favorites of my own.

In many cases of urethral neurosis, surgical interference is required, thus a contracted meatus must be cut, a stricture dilated or cut, a hernia or varicocele operated upon or properly supported, etc. *The paramount indication from a surgical standpoint, is the relief of obstructive and inflammatory lesions of the genito-urinary tract.*

Cases of irritability and hyperæsthesia of the testis are by no means promising. The use of anodynes is ordinarily reprehensible, as the disease is chronic in character, and a narcotic habit may be readily acquired. If hygiene, the steel sound, the suspensory bandage and marriage do not cure, the case is apt to be hopeless. Galvanism and the application of ice bags, are said to be of service. Castration is not to be thought of, but the idea suggests itself to me that in an obstinate case, stretching the spermatic cord with incisions into the tunica albuginea might be successful. If varicocele exists, an operation may be successful in curing the neuralgia. Hammond suggests pressure upon the cord for the relief of obstinate cases, upon the theory that in this way the sensibility and conductivity of the affected nerve fibres will be obtunded. Return in opposite after removal affected organ.

A very interesting case showing the great annoyance which may reflexly arise from slight irritation of the genito-urinary tract came under my observation a few days ago. A gentleman 28 years of age had been troubled by frequent micturition, especially at night for some years. At times he would be compelled to rise four or five times at night to evacuate his bladder. The only point in his history of any importance was a gonorrhœa some seven or eight years ago. He confessed to masturbation and sexual excess in times past, but stated that sexual apathy had prevailed of recent years. On examination, I found a meatus which had been badly cut by some surgeon one year ago. Just within it was a very irritable and resilient stricture of a calibre of twenty Fr. Not a stricture perhaps, in the eyes of some surgeons, but a decided stricture in my opinion. This contraction was so irritable that attempts at exploration threw the entire canal into a state of spasmodic contraction. I found it impossible to pass a bougie through the deep portion of the canal. Cocaine was applied and a meatotomy at once performed. As soon as the meatus was free, I passed a 32 Fr. solid steel sound into the bladder without the slightest effort. The night of the operation, the patient had the first uninterrupted sleep that he had enjoyed for years, this experience being repeated every night following until he left for his home in the West.

We have here a case of vesical and prostatic hyperæsthesia, and chronic spasmodic stricture—urethrismus—instantly relieved by removing the reflex source of irritation, a resilient and irritable meatal contraction.

Another interesting case of a somewhat different type is at present under my care. This case shows how posterior irritation may reflexly excite disagreeable symptoms in the anterior portion of the genito-urinary tract. A young man of twenty-five who had suffered from several severe attacks of gonorrhœa, presented himself to me complaining of severe burning and hot, lancinating pains along the pendulous urethra, localized at times at a point one inch posterior to the meatus. These painful symptoms were chiefly manifest after urination, although present in the intervals. The patient was extremely neurotic and suffered from sexual hypochondriasis. Otherwise he was in normal condition. The urine presented no pathological features, save tripper fäden and mucous casts of the prostatic follicles of the characteristic horse shoe nail variety. Examination with the bulb showed a urethral calibre of 34 French, and an absolute freedom from contractions. There were several points of tenderness in the penile urethra and excessive tenderness in the prostatic region. Rectal examination showed the prostate to be slightly enlarged. I made the diagnosis of urethral neuralgia and hyperæsthesia dependent upon posterior urethritis and follicular prostatitis. There was no cutting to be done, and the treatment therefore, consisted of intermittent dilatation with large sounds, and the application of nitrate of silver solution to the prostate. These applications were alternated with the application of the continuous current, positive pole, to the deep urethra. Internally, tonics were given, the tr. ferri chlor. being mainly relied upon. The case has slowly but markedly improved, a fact which is particularly gratifying in view of the stubbornness of such cases.

I wish to state, in passing, that I envy those surgeons who have such brilliant success in the management of this type of genito-urinary neurosis as is claimed by some. Personally, I had rather see the gentleman with the cloven hoof walk into my office, than one of these patients.

The explanation of the obstinacy of such conditions is to be found chiefly in faulty sexual hygiene, matter over which we have but little control.

As illustrative of the interesting character of some of the cases described, I take the liberty of presenting the following, selected from my case book.

Case 1.—Reflex vesical irritability and intercostal neuralgia from contracted meatus. W. R., age 39. This gentleman had had numerous attcks of gonorrhœa in his youth, the last attack having occurred about fifteen years ago. Since this last attack he had been troubled with frequent micturition, necessitating his rising six to eight times during the night, and causing great irritability of mind. Micturition was occasionally quite difficult, requiring fifteen or twenty minutes for its completion, the stream being especially slow in starting. Every spring and fall and whenever he was overworked he suffered from a severe attack of pleurodynia, which had been variously diagnosed as pleurisy, impending pneumonia, cardiac neuralgia, intercostal nearalgia, etc. In two of these attacks in which I attended him, there was an elevation of temperature of about four degrees, with considerable prostration, leading me to believe that the attacks were of a rheumatic character. On examination of the urethra, I found the meatus so small as to barely admit a small probe, and excessively tender and inflamed. A slight gleety discharge was noticeable, which the patient stated had been a constant symptom for some years. I at once enlarged the meatus to 34 French, and attempted a thorough exploration of the canal. I found that steel sounds would not pass the muscular urethra on account of the intense spasm which they induced, soft bougies, however, passed readily up to 18 French. Above that size could not be passed without producing intense pain. No organic contraction of the canal could be demonstrated by either urethrometer or *bougies a boule*. The second night after the meatotomy, the patient slept soundly for the first time in some years, and he has continued to secure his natural rest ever since, it being now three months since the operation. The flow of urine has become quite free, and starts as soon as an attempt at micturition is made, the act of micturition being of normal frequency. A marked improvement in the general health is noticeable, and the nervous irritability has in great measure disappeared. There has been some increase of weight, but as the patient is naturally spare, this has not been very marked. The attacks of pleurodynia have not recurred, although the usual time for their occurrence has passed; and as time goes on, I am confident that the theory of their dependence upon the urethral irritation, will be confirmed. The gleet has disappeared entirely, and there has been a decided increase of sexual vigor; in short, as the patient expresses it, he is "himself again."

Case 2.—General sympathetic disturbance and neuralgia of the testes, from stricture of large calibre and follicular prostatitis. J. G. R., aged 45. This gentleman had had several attacks of gonorrhœa, the last one having occurred some 20 years ago. For the last four years had been suffering with irritation of the urethra, which had been referred to stricture, and treated by dilation. Later on he had been "quacked" for diabetes, prostatic enlargement, Bright's disease, rheumatism, and several other afflictions, with no effect save to convert the patient into a confirmed hypochondriac. At the time he consulted me, he had been suffering from paroxysmal pain in the testes, with occasional "burning" sensations in the testes, perineum, and cranial vertex, and pains of a rheumatic character in the limbs. On examination of the urethra I found that it would admit an 18 English sound quite readily, save that some pain was experienced at a point one inch from the meatus. At this spot the *bougie a boule* demonstrated the existence of a linear stricture of large calibre. The prostate was found to be somewhat tender, but not enlarged. On examining the urine I found that it contained membranous shreds, which from their appearance I judged to be from the prostatic urethra, and the result of follicular prostatitis. A slight gleety discharge was noticed, evidently of a similar origin.

The meatus and stricture were cut to a calibre of 40 French, with a complete relief to the neuralgia of the testes. The rheumatism in the limbs has greatly improved, but the feeling of heat in the testes, perineum, and head has in a measure persisted, although much better. These latter symptoms I attribute to prostatic irritation, more particularly because applications to the prostatic sinus, of a sedative or astringent character, produce a marked and speedy amelioration of them. I have found also that the shreddy appearance of the urine was increased by each application to the prostate. Hot boracic acid irrigation has been substituted for these applications. and the case is slowly improving. The connection between the neuralgia of the testes and the stricture in this case is demonstrated by the improvement resulting from urethrotomy.

Case 3.—Pseudo-impotence from contracted and irritable meatus. This case and case 4, I will not give in detail, but will present the salient points:

A young man of 27 had suffered from several attacks of gonorrhœa, the last of which ran into a gleet which lasted about a year. There has been no trouble with urination, but about six months before I saw the patient, he noticed a loss of sexual power. He would succeed in securing an erection at times, but erection would suddenly cease in the performance of the act of copulation. On examination I found the penis and testes apparently normal, but the meatus was quite narrow and excessively sensitive. There was no deep or penile stricture.

The meatus was incised to 34 French, and sounds passed to the bladder every third day for several weeks. At the end of a month improvement was reported, and in about two months the patient reported himself as entirely recovered from his sexual disability.

Case 4.—Vesical atony from contracted and irritable meatus. This patient, 40 years of age and a gambler by profession, gave the usual history of numerous gonorrhœas and also of syphilis. Micturition had for a long time been attended by pain and smarting at the meatus, and a slight gleet had been present for some years. For about a year the stream had grown less and less forcible, until quite a strenuous effort was necessary to empty the bladder. On examination the meatus was found to be only moderately contracted, but very tender, the lips being everted and reddened. No deep strictures were discoverable. The feeble flow of urine through the catheter demonstrated the vesical atony. As the obstruction was only moderate and was congenital, the atony was explicable only upon the theory of reflex spasm of the cut off muscle and inhibition of the detrusor urinæ. Meatotomy to 40 French resulted in an almost complete cure as demonstrated by examination six months after operation.

Other cases of a neurotic character have occurred in my genito-urinary practice, but these cases will serve for the purpose of illustration. In all of my cases, due attention has been paid to general hygienic and medicinal measures, but the details of treatment would simply result in prolixity, without adding to the value of the report.

I have found that reflex neuralgia of the testes, penis and cord, and spasmodic stricture are by no means rare as several instances among my patients serve to demonstrate.

Discussion.

Dr. J. G. Kiernan, Chicago, Ill.:—The subject of reflexes is an interesting one, and a Chicagoan is in duty bound to take it up, for we have a remarkable genius there who cuts out "pockets" of the rectum, removes the clitoris, the ovaries for insanity and neuroses, and then the patient recovers—if he or she, as the case may be, does not jump out of a window. He claims to have cured moral insanity by removing pockets of the rectum. Some of the patients are no better than they were before these pockets were removed. He has cut the "pockets" of several reporters, but they are as great pathological liars as they were before. To come down to the main point, there are certain instances in which we are justified in a limited use of the reflex hypothesis, in connection particularly with the genito-urinary organs of the male. It is well known that the first symptom of renal disease in horses is paraplegia, and what occurs in the lower animals may occur exceptionally in mankind, especially in those degenerate types who resemble animals. These cases are extremely rare, and the burden of proof rests on those who report them.

Dr. Hughes for the last twelve years, in the *Alienist and Neurologist*, has denounced the abuse of spaying and removal of the tubes. I have seen five cases in an insane hospital in which the lucid interval was converted into excitability by oöphorectomy, and such cases frequently appear in the literature. These gynecological procedures have had the same result. That gynecological procedures have been scandalously abused in the treatment of the psychoses and neuroses, is the opinion alike of gynecologists and neurologists. The "reflex" hobby has been ridden to death.

Dr. C. H. Hughes, St. Louis, Mo.:—I think the paper of Dr. Bremer is a most admirable and pertinent one, and when it is published in the Transactions it will go before the general profession, where it will do some good. I think that the time has come for iterating and reiterating the fact that this reflex theory has been carried farther than the physiological, anatomical and pathological facts warrant. We know from the particular direction that our own studies have taken for the past thirty years or more in regard to this subject, that some of the claims for the reflex disease are absolutely groundless, and physiologically, pathologically and logically ridiculous. It is not difficult to understand how a wave of irritation, starting from a congested ovary, has been a point of local irritation, may be transmitted along the ganglionic system so as to involve the heart in ganglionic functional disturbances. But it is a difficult thing for a neurologist to understand how an indurated cervix can by any process of reasoning, based upon anything known in the physiology of the nervous system and its connections; or how a cicatrix, which twenty-five or thirty years ago was made with impunity and said by gynecologists to be harmless, can be the *fons et origo* of mental aberration. These gentlemen mistake sequences in the neuropathic for consequences, and jump at the most erroneous of conclusions, and gynecology has brought itself into disrepute during the past three decades in its history to such an extent that its own votaries are to-day engaged in retracting their formerly promulgated errors. They call them "nerve" counterfeits of uterine disease, because they now understand better than they did a quarter of a century ago the nervous mechanism and nervous diseases of woman. The very diseases which in the literature of gynecology were treated of twenty-five years ago as gynecic neuroses dependent upon uterine diseases, are confessed to be neurological counterfeits of uterine disease. It is the province of this Section to further enlighten the general profession, and I am not sure but that some of the genito-urinary surgeons may receive some enlightenment in the same direction from neurology. Fortunately they have not gone so far. If Dr. Lewis A. Sayre had taken more account of the neuropathic condition of his patients and their constitutional tendencies, he would not have expected so much from a circumcision, and attributed the results of change of air and of environment, and general tonic treatment, to his little operation on the foreskin.

Can any gentleman tell me how we might have a facial neuralgia dependent upon ovarian congestion? Can any gentleman explain to me by what physiological process of action it can be shown, or by well established clinical experience it can be demonstrated, that we can have such a pathological result from a cicatrix of the cervix? Yet it has fallen under my observation to have treated such patients. I remember to have read of a case months ago which was finally cured, which had undergone nine years of gynecological torture upon the hypothesis that the patient's neuralgia was a reflected uterine irritation. The woman's husband was a doctor and her brother was a doctor, who blamed the woman's uterus, and their suggestion was confirmed by subsequent consultants.

While I say, as a neurologist, that all sources of a peripheral irritation should be removed in suffering patients, because the neuropathic are a peculiarly irritable class of patients, and local irritation depresses and lowers general nerve tone and thus aggravates neuropathic conditions elsewhere, intensifying actual nervous conditions in other parts of the system and bringing into activity latent states of instability through lowering of the nutrition of the nerve centers, the ever ready reflex theory is far too often misapplied and too unwarrantably evoked.

Dr. William Fuller, Grand Rapids, Mich.:—Personally I desire to thank Dr. Bremer for his paper on account of the high moral tone of the sentiments expressed in it. I feel that the Section is to be congratulated upon having such a paper as that. I think that the abdomen is too often opened upon too slight pretext. A careful diagnosis is now ignored. I can recollect a time when it was more disgrace to a surgeon who upon opening the abdomen should find what he did not before expect, than it is now to kill a patient on the table. Laparotomy is an indefinite word, and should be confined in its use to those instances in which the abdomen is opened by mistake or for information only. The glory of having "made our last fifty or hundred laparotomies" is to some persons a dangerous sentiment and to be deprecated, as an aspiration liable to disgrace legitimate surgery in the eyes of the profession and of the people. The present craze to unsex woman is an outrageous abuse of the art. The ovaries of one woman were removed on account of pains from gall stones. I would suggest the removal of the testicles for slight nervous disturbances in males as a counteracting measure.

Reflex derangements mostly follow definite courses in the nervous system, affecting related bodily functions and mental emotions. Sexual diseases affect the passions, produce hystero-epilepsy and moral defects. Masturbators become religious melancholics, and nearly all the peculiar religious sects and wild philanthropic schemes have their foundation in derangement of the sexual system.

Dr. J. E. Emerson, Detroit, Mich.:—I desire to personally thank Dr. Bremer for his excellent paper and for its vigorous tone. I have experienced the grievances which he has expressed from fanatics who have made so much of the reflex neurosis theories in regard to disease, more especially in cases of insanity, where many practitioners insist upon making a vaginal examination in every case of insanity in a female. Dr. Goodell has called attention to the fact that women have other organs besides the uterus and its appendages, whose diseases may excite disorders of the nervous system exactly as they do in men.

In spite, however, of my approval of the paper, I must say that my own experience compels me to utter a word of caution in regard to certain ocular defects which cause reflex neuroses in the form of headaches, or even more serious functional disorders. In many cases I have been convinced that astigmatism or a defective coördination of the optic muscles produced these conditions; but I feel grateful to the doctor for his paper, which attacks this fanaticism so vigorously.

Dr. H. N. Moyer, Chicago, Ill.:—While there is a certain element of truth in the reflex theory of disease, still I think it has been carried too far, and Dr. Bremer's paper is just what it ought to be. Dr. Goodell and other gynecologists are finding it out. There are a great many counterfeit conditions of the uterus and its appendages that are mere expressions of a general neurosis. I think the true principle lies between these two extremes. There is an immense amount of harm done by some men in looking for some little point of irritation in the special organs of which they treat, and the moment they find an array of symptoms they attribute them to that one thing.

Dr. G. Frank Lydston, Chicago, Ill.:—Mr. Chairman, in regard to what has been said of laparotomy being overdone and carried entirely too far, if I am not mistaken I was a pioneer in ridiculing that particular thing.

Dr. Hughes said the neurologist could teach the genito-urinary surgeon some things in regard to reflexes. I have no doubt about it, and that is precisely why I am here. A friend of mine asked why I was going to read a paper in the Neurological Section. I replied, "simply because I can get a more scientific discussion on my paper in this Section than anywhere else." I came here to learn, not to teach.

There are certain points regarding the abuse of gynecological operations, particularly with reference to the cure of mental phenomena, that have been suggested to me by practical experience. Recently I read in the Transactions of the Southern Surgical and Gynecological Association a report of some 30 laparotomies, successful and unsuccessful, reported by a Southern surgeon, in which he recounted a number of patients upon whom he had operated for the cure of mental phenomena. Of those who lived through the direct and remote results of the operation, several were cured, others were not, and still others committed suicide. One I believe, was cured at the end of a year, after operation. Such cures are probably cases of acute mania. I had an illustration of such a case in my own practice a short time ago. A young lady of extraordinary talent, with a high-strung hereditary nervous temperament, and extremely neurotic, became suddenly insane as a consequence of over study. I was called to see her, not knowing what I was going to find. I found her violently insane, and she had been in that condition for some little time. One of my professional friends with whom I conversed, took the ground that laparotomy was indicated, and that the ovaries ought to be removed. As I was interested in the family, I said, "we will wait a little." At the end of 18 months the young lady became perfectly well. I am satisfied that if I had not had a personal interest in the family, oöphorectomy would have been done, and the case cured—in a year and a half.

As far as my own position is concerned with regard to the reflex genito-urinary neuroses, I do not wish to be understood as trying to diagnose something out of nothing. I believe we have conditions of the genito-urinary organs—painful or otherwise—which produce effects upon the brain or nervous system in general. I believe that the diagnosis of reflex nervous irritation can not be thoroughly established until we can, as Dr. Hughes suggests, map out a definite relation between the source of irritation and the reflex. I do not believe ovarian irritation can produce a facial neuralgia any more than that the moon is made of green cheese. It is necessary for us to find the primary seat of irritation in order to justify a diagnosis of reflex derangement.

A certain gentleman attending this convention has had an experience in his own case, that shows a definite relation between a tendency to melancholia and nervous depression, and genito-urinary irritation. The case was treated for neurasthenia and other things by a well known neurologist in the city of Chicago. There was no explanation given as to the localization of this particular lesion. I happened to know that this gentleman had an irritable prostate. He subsequently came to me, I examined him and found an irritable meatus with chronic inflammation behind it. He also had prostatitis. Meatotomy with the application of nitrate of silver to the prostate gave the gentleman the greatest possible relief.

Dr. Hughes was vigorous in his condemnation of the theory of certain remote nervous disturbances being produced by cervical reflex irritation. How then must we explain those cases of obstinate vomiting in pregnancy, unquestionably due to cervical irritation, which are relieved by moderate dilatation of the cervix? There seems to be a direct relation between cause and effect under such circumstances. One point should not be overlooked with regard to the relation of irritation of the genital organs and remote functional disturbances. A comparatively slight irritation in this region will produce a disproportionate functional disturbance elsewhere because as we well know, there is no location in the body in which the sympathetic supply is richer than in the sexual organs. The structure of these organs proves conclusively, the greater importance of irritation of these tissues as compared with others with relation to the liability to reflex irritation of parts more or less remote from the primary disturbance.

Mignonette for Tapeworm.—In Russia the flowers of the mignonette are used as a remedy for tapeworm. A decoction of the flowers is made, and the liquid is drunk fasting. It is then followed with a dose of castor oil. The entire worm is rejected in a few hours.—*Pacific Record.*

RETINAL EXCITATION OF CORTICAL ORIGIN IN VISUAL HALLUCINATION.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY C. G. CHADDOCK, M.D.,
OF TRAVERSE CITY, MICH.

The question to be considered under this title is: Does ideational activity of the cerebral cortex ever induce centrifugal excitation of sensory end-organs through their afferent sensory nerves, and thus lead to the sense of objectivity, or projection, that is the characteristic feature of hallucination?

For the sake of clearness, consideration of the question is confined to the sense of sight.

Quite commonly hallucination is made to include all phantasms that have no other than a subjective foundation; but to answer the present question, a stricter differentiation of subjective phantasms than the common definition implies, is necessary. Phantasms having a peripheral origin, though without objective, or external, cause, must be distinguished from those having a central origin. Following Emminghaus,[1] the former may be allowed to fall within the term *illusion;* and hallucination may be made to include only those phantasms that have a purely central origin.

In answer to the question of the occurrence of peripheral sensory excitation of central origin, authorities are not in accord, but the voice of affirmation is much stronger than that of negation.

The belief ordinarily entertained is that in an hallucination there is a backward nervous "current," from center to periphery, which perfects the sense of its objectivity.

The prevalent idea is an assumption; for, in the nature of the case, such a reverse "current" cannot be proved to occur; and we may therefore examine the ground upon which this assumption rests, and make a theoretical application of the principle it involves.

Emminghaus[2] says: "The assumption that in hallucination there is a nervous excitation that advances from center to periphery, rests essentially upon the fact that under certain circumstances, visual phantasms *change their location.*"

Krafft Ebing[3] states that with perfection of objective projection of an hallucinatory image, there is probably secondary excitation of the organs of sense involved.

Wundt[4] also holds to this view, basing his opinion upon the statement that visual hallucinatory images may excite after-images, as well as upon the fact that the phantasms move with movements of the eyes.

Sir David Brewster[5] believed that all hallucinations involved the appropriate sensory organs. Esquirol[6] promulgated the theory of the purely central origin and nature of hallucinations.

While D. Hack Tuke[7] thinks that cortical activity is in itself sufficient to produce hallucination, he still allows that the end-organs may be involved secondarily in some cases; and as criteria for the determination of secondary (?) retinal excitation he states as follows:

"If visual hallucinations present the same phenomena as those observed in luminous after-images, they may be regarded as involving the retina."

The phenomena referred to are that the phantasm cannot be artificially doubled; that it covers real objects; and that it moves with the motion of the eye. These phenomena include all the evidence of secondary retinal excitation that other authorities mentioned adduce.

But in visual hallucinations all these phenomena might be present without involvement of the retina at all; that is, they do not demonstrate that the retina is involved. For the visualization of a mental image not involving the retina would necessarily be projected in the immediate field of vision and cover objects in that field, or be fused with them. Thus while these tests will demonstrate whether a visual phantasm is of subjective or objective origin, in the nature of the case it cannot prove involvement of the retina, or at least that retinal excitation is of central origin, when the phenomenon is thus demonstrated to be subjective.

With primary subjective retinal excitation and secondary elaboration of the impression (illusion), we are not dealing here; phenomena of this nature are in perfect harmony with the physiological process of visual perception. It is only the possibility of the reverse process, with the primary stimulus having a central origin, that is here called in question.

Centrifugal excitation of the retina in visual hallucination is not a *sine qua non.* There is abundant evidence to prove that mental images undergo objective projection in the absence of the sense organs that would be involved. Where visual hallucinations have occurred with atrophied optic nerves, if centrifugal excitation took place the element of objectivity must have been supplied without the aid of the retina.

But let it be assumed, that a reverse stimulation occurs and affords the elements of distinctness and objectivity essential in hallucination. For the sake of clearness and simplicity, let it be assumed that the mental image is to be projected visually and involve one retina; that the mental image is that of an object of two dimensions of a given size situated a certain distance from the eye. Then, in accordance with the assumed premises, if this image be projected with an accompaniment of corresponding retinal excitation which assists in the induction of the sense of its distinctness, the retinal area excited must be exactly that area that would be stimulated if the actual figure were before the eye under the conditions of distance and dimension imposed.

In the absence of knowledge of any nervous mechanism designed to select nerve-fibres which shall convey the nervous excitation back to the retina, we may allow that cortical activity attending consciousness of the image in itself conditions such a selection of nerve-fibres as must convey to the retina excitation that distributes the stimulation there in the form of the image. In order that the image thus formed on the retina shall add distinctness to the mental image, it must, in the whole of its dimensions, be confined to the very limited area of the retina in which, as is well known, distinct vision is possible—the fovea centralis. For if the secondary retinal image were indistinct, as it would be, if disposed upon an indifferent retinal area it could not reinforce the distinctness of the mental image. If, for the sake of distinctness, the retinal image must be confined to a certain limited area, and the necessity for this seems clear, then its objective projection would necessarily be like the projection of the distinct image on the retina when the eye is at rest. The apparent visual angle would be all that could assist in the projection of the secondary retinal image. But the visual angle in itself has no determining effect in developing an idea of space; and therefore in the assumed case it could alone have no effect in determining definite projection of the assumed centrifugally conditioned image. Therefore, the secondary retinal image, even though it correspond in form with the primary mental image, could not in itself condition an objective projection in harmony with the idea of objectivity with which the image is present in consciousness, and therefore, for distinctness of projection of the mental image, the aid of some other element than that supplied by the secondary retinal image would be required.

[7] Hallucinations and the Subjective Sensations of the Sane, Brain, Vol. xi, p. 41.

Now, let the hypothesis be complicated by bringing binocular vision into consideration; let the assumed mental image effect both retinæ. Then it must be assumed that the area of stimulation, in one retina,is physiologically correlated with the stimulated area of the other, in order to have perception of a single image. But in this instance, as in the preceding, the projection that results in that the images are identical, will be subject to the same conditions as obtained under the preceding assumption.

To still further complicate the matter, let the image, to be projected, be inverted with the third dimension.

An object having three dimensions seen in binocular vision impresses simultaneous images on each retina that are not identical, save when the object is seen in distant vision; in fact, an object of three dimensions viewed with convergence of the visual axes, may impress images on the retinæ that differ almost absolutely from each other. It is largely owing to the disparity of these simultaneous images of one object on two co-related retinæ, which undergo subjective fusion into one image, that the idea of the third dimension of the object is derived. Now, in the assumption of the reverse stimulation of the retinæ by a mental image of an object of three dimensions, it would not suit the purpose of the assumed secondary excitation were this single mental picture to be photographed identically on each retina; for then the objective projection of them would not possess that want of identity necessary for the induction of the sense of its third dimension. But a single mental image cannot be consciously resolved into two images from which the former might be derived, without having consciousness of two images successively; and it is therefore impossible to conceive, when the mental image is derived from two or more aspects of an object, how consciousness of the single image could condition a centrifugal excitation of co-related retinæ by disparate images. Here again the centrifugal retinal excitation would necessarily lack that determinateness to supply which it is assumed.

The fact is that all our reproduced mental images are complex simultaneous reproductions of a series of simple visual preceptions that were originally received in series and fused by association. The limitation of visual perception conditioned by retinal structure and function is in extreme contrast with the almost unlimited power of simultaneous reproduction in combination of serial, simple perceptions in memory. In the very nature of the case, then, a complex mental image could not condition a centrifugal excitation that is objectively impossible; the retinal excitation, were it to occur, would necessarily be simple, or at most but a reproduction of some element of the mental image. Thus exact simultaneous correspondence between the mental image and any secondarily induced retinal image, is impossible.

Under all circumstances, then, under which we can theoretically conceive a mental image as exciting a reverse "current" to the retina, there would be more or less disparity between the mental image and the resulting sensory excitation; that is, that additional quality with which secondary sensory excitation is presumed to supply the primary mental image for the sake of distinctness, is found to be so indeterminate, that if it were to occur it could only confuse the original mental image.

But if secondary excitation of the retina could not intensify the quality of distinctness in a mental picture, might it not, nevertheless, add the element necessary for its objective projection? Let it be assumed that it does. Then any visual sensation that does not correspond with the mental image present in consciousness is capable of adding the sense of objectivity: any elementary visual sensation, one as well as another, would serve the same purpose.

If this be true, what need is there to assume that there is any reverse sensory stimulation at all? The retina, like all sensory organs, is almost constantly subject to inadequate subjective stimuli, and any or all of these might aid as efficiently in inducing a sense of objectivity as an indeterminate stimulus travelling backwards.

Discussion.

Dr. Wm. Fuller, Grand Rapids Mich.:—Dr. Chaddock's paper reminds me of a case that came under my observation, in which a man was able to see two images with one eye—*monocular diplopia*. When both eyes were open he saw two images of the same object, a true one and another smaller one nearer to him, and placed a little above and to the right. When the left eye was closed both images were seen in the same position, but when the right eye was closed the true image only remained. With the right eye closed he could place his finger on the head of a pin at the distance of two or three feet from the eye, but with the *left* eye closed or with both eyes open he was unable to do so, on account of the uncertainty of the position of the object. There was paresis of the left extremities, especially of the arm. The man had received a severe blow on the right side of the head, over the coronal suture, about a month before, at which time he was unconscious for several hours. The diplopia was observed immediately upon the recovery of consciousness, and has remained up to the time of examination. In walking he lifts his feet high, as the floor appears to him to be elevated before him. The defect in vision was corrected by prisms and disappeared after a short time, about two weeks.

Dr. Welsh, of Grand Rapids, saw the case with me and reported: Distant vision, right eye, 20-30; distant vision, left eye, 20-30. Ophthalmoscope showed a normal fundus.

His opinion was that the false image was the relict of a mental impression which was forgotten after correction had been maintained for a sufficient period to efface it. The case is an interesting one, and I would like some gentleman present to give a satisfactory explanation of it.

The Chairman:—I have not seen a case like it, and am not aware that there is such a case described in literature.

Dr. James Taylor, of London, Eng., stated that such a case was reported in the Transactions of the Ophthalmological Society of Great Britain.

Dr. L. Bremer, of St. Louis, Mo., had seen two cases of monocular diplopia, one case being due to a cerebellar tumor. A number of other physicians saw this case.

Dr. J. H. Kellogg, of Battle Creek, Mich., also reported a case of monocular diplopia, and stated that ophthalmologists believe that such cases are due to irregularities of the cornea or crystalline lens. He had a case in which a man declared that he saw three images at one time with one eye, but these images were not always present. The speaker found only two objects present.

Dr. L. Bremer stated that the eyes of the individual whose case he had reported had been examined by a competent ophthalmologist and nothing had been found to throw light on the condition. The whole question of cortical vision is still very much mixed.

Dr. C. K. Mills, of Philadelphia, said the separation of the optical or cortical field of vision by some lesion might possibly furnish an explanation in some cases, but we have no definite knowledge in regard to these cases.

The Chairman:—I do not believe it is possible for us to have a diplopia through an affection of the cornea or lens. Displacements and disturbances of the lens are exceedingly common; but so far as I know, the condition under consideration is a very rare one.

EARLY NATIONAL LEGISLATION ON THE SUBJECT OF QUARANTINE.

BY STEPHEN SMITH, M.D.,
OF NEW YORK.

The approach of cholera again to our shores, will awaken a new interest in the character, management and efficiency of our quarantine defences against foreign pestilences. The crucial test which is now applied to our present system of State quarantines, and the evidences of their total inadequacy to meet a great emergency, will doubtless renew with great vigor the popular agitation in favor of a National quarantine organization. As a contribution to the discussion of that subject the following facts in regard to the efforts made in the first sessions of Congress may prove of interest, if not of permanent value.

On the organization of the Federal Government, in 1789, several of the sea-board States had quarantine laws and regulations of more or less efficiency. In most of these States the laws were originally adopted by the colonial governments, and in some they had been in effect for nearly a century. South Carolina enacted a quarantine law as early as 1698, Pennsylvania in 1699, Rhode Island in 1711, New Hampshire in 1714, New York in 1758. These early laws were chiefly designed to prevent the importation of small-pox, though yellow fever and ship or typhus fever had attracted attention as diseases capable of transportation. Yellow fever had several times, but at long intervals, been epidemic in seaboard towns having a large commerce with the West Indies, as at Boston in 1693; Philadelphia in 1699, 1741, 1747, 1762; New York, 1702, 1743; Charleston, 1699. But it did not attract attention nor excite great public alarm until commerce with the West Indies, after the Revolutionary war, was fully established. From 1762 to 1791 the country was entirely free from yellow fever. This immunity has been attributed to the parliamentary acts known as the "commercial monopoly," and the war of the Revolution, which prevented all direct commerce with the West India ports and the United States. With the restoration of an active commerce with the West Indies yellow fever again began to make its appearance in those ports where this trade was most active. The first outbreak occurred in New York in 1791, in the West India shipping, and the pestilence proved very severe and fatal, and caused great public alarm. In 1793 it appeared in Philadelphia, and was then universally attributed to the shipping from the West Indies. The pestilence now began to excite public alarm, especially in neighboring cities having personal and commercial intercourse with Philadelphia. New York, Chestertown, Baltimore, and Annapolis took active measures, and finally established rigid land quarantines against Philadelphia. In 1794 it appeared in New York, Philadelphia, and Baltimore, and the public excitement was so great that there was a renewal of the land quarantines in various sections. In 1795 the fever again prevailed at New York and Norfolk, Va., and vigorous measures of protection were discussed and adopted by the authorities of other exposed towns. It would be impossible at this distant period to properly estimate the current events of the time when yellow fever first became widely epidemic at the close of the last century, had we not passed through a similar epidemic in 1878–'79. Then, as now, the disease was regarded as contagious and infectious, and all of the precautionary measures were designed to prevent the contact of the sick with the well. Maritime and land quarantines were established, and the latter was enforced with the shotgun. In most of the details the measures of prevention in 1793 were the same as in 1878, more than three-quarters of a century later.

In order to understand the first act of Congress relating to quarantine it will be necessary to refer to the exciting events of that period. The following extracts from the papers of that date, kindly furnished by Dr. J. M. Toner, of Washington, reveal the intense excitement of the communities living in immediate communication with the centers of infection:

In 1793 the citizen of "Chestertown," Pa., held a public meeting. Their first resolve was:

> "It appearing to this meeting, from the information they have received, that the said disorder (an infectious disorder which at present prevails in the city of Philadelphia) has extended itself from Philadelphia to Trenton, Princetown, Woodbridge, and Elizabethtown, on the post-road to New York, it is the opinion of the meeting that the same has been occasioned by the stages passing through those places."
>
> "2d. *Resolved*, therefore, That it is necessary and proper for the welfare of the inhabitants of this town that the stages should not pass through this place, and that notice of this resolution be given to the stage owner; and further, that if the said owner should refuse to comply with this resolution, that then the chairman shall call a second meeting to deliberate on and adopt such measures as self-preservation may in that case dictate and justify."

The mayor of New York, Richard Varick, issued a circular to the profession of that city, September 11, 1793, stating that "Great apprehensions are entertained by many of our fellow-citizens that, notwithstanding every prudent and legal precaution, the contagion of that distressing infectious disorder may be brought into this city by means of the open intercourse between the two cities, which cannot be lawfully interrupted by any power in this State." He informed them that a hospital had been provided for the sick, and requested reports in writing of every person arriving from Philadelphia who should be taken sick.

On the 17th of September, it appears that

> "The corporation, at the request of citizens of New York have come to a resolution absolutely to prevent all intercourse between this city and the city of Philadelpia, and for this purpose guards are set at the different landings with orders to send back every person coming from Philadelphia to this city; and if any persons shall be discovered to have arrived in this city after this date, it is the resolution of the citizens immediately to send them back."

On the 12th of September of the same year the governor of Maryland issued a proclamation establishing a rigid maritime and land quarantine. One provision is as follows:

> "And I have, with the advice of the council, thought further to direct that all persons coming to Baltimore Town, to Havre de Grace, to the Head of Elk, or by any other route making their way into this city from [illegible] other place known to be infected with [illegible] shall be subject to be examined, and prevented from proceeding, by the person who will be appointed for the said purpose."

The plan of requiring each traveler to carry certificates of not having been recently exposed to the fever was also adopted, as appears from the following: On the 24th September, the citizens of Havre de Grace held a public meeting

> "to take into consideration their exposed situation on the post-road from Philadelphia, where a malignant fever now rages with great virulence" and passed the following resolutions: 1. That it is our opinion that no persons should be suffered to cross the Susquehanna who do not bring with them certificates, signed by some magistrate, of their not having lately come from Philadelphia or any other infected place. 2. That the citizens of this place embody themselves and act as a guard at the lower ferry of the Susquehanna to prevent any person crossing that does not come with the above certificate.

In other instances travelers were questioned under oath as to their recent movements. The corporation of Annapolis, Md., passed an ordinance September 27, 1793, appointing a health officer and requiring him

> "To examine upon oath or otherwise all strangers that may come to this city by water or in stages, and if, upon examination, he shall be of opinion that there is no reason to apprehend that the said disease, or any other malignant disorder, will be communicated or introduced by the person or persons so examined, he shall grant a certificate or certificates to that effect." Another officer was required "on Mondays and Fridays to attend at the entrance into the city by land and give information to the said health officer of the arrival of the stage." The inhabitants were forbidden to harbor any traveler who had not been examined, as follows: "That whatever inhabitants of this city, or the precincts thereof, shall after the publication of this by-law, take or receive into his or her house or family any person who shall come to the city in a stage, or any person who shall come to this city by water, until such person shall have obtained a certificate from the health officer of the city . . . shall forfeit and pay the sum of three pounds."

The inconveniences which travelers experienced by this land quarantine may be inferred from occasional letters of correspondents. A gentleman who left Philadelphia for the South, wrote, September 25:

> "We were stopped about seven miles from Baltimore by armed men who used us with every indignity and hatred truly indicative of *malice prèpense*. These detained us in the stage from five in the afternoon until ten the ensuing morning. During this interval one of these ruffians, who appeared to be a German, snapped his piece at one of our party who seemed inclined to leave the stage with the apparent design to go among the bushes near the road. This guard in their tender mercy were pleased to hand us a piece of dry cheese on the end of a pitchfork. After this quarantine we were permitted to go to Gray's Garden and thence to perform another for the space of two days and nights."

Another writes on the same date from Philadelphia:

> "On Friday evening all the New York and Philadelphia land stages returned to this city with their passengers mortified and fatigued. They were refused a passage through New Jersey. One of the drivers had a very narrow escape with his life, being cruelly fired upon at Trenton; the ball passed within a few inches of his ears. No provisions were to be obtained on the road nor any accommodation of any kind even for the lady passengers."

In 1794 Philadelphia had an opportunity to retaliate upon Baltimore, where yellow fever prevailed severely. October 3, 1794, a public meeting was held in Philadelphia "to take into consideration the propriety of stopping all communication with the town of Baltimore during the present contagious disorder now raging in that place." At a subsequent meeting it was unanimously resolved "to stop the intercourse between this city and Baltimore, by land and water, on account of the contagious disorder now raging there; and a committee of twenty was appointed to see that this retaliation be carried into effect in such a way as to occasion the least possible injury to the public or breach of humanity to individuals." The governor of Virginia also issued a quarantine proclamation against all vessels from the port of Baltimore.

In 1795 Philadelphia also adopted a rigorous maritime and land quarantine against New York and Norfolk, Va., very much to the annoyance of New York. The governor of Pennsylvania, Hon. Thomas Mifflin, requested the Board of Health of Philadelphia, August 29, 1795, to inform him as to the prevalence of "a contagious disorder" in New York. The reply was that there was sufficient reason to believe that "a contagious fever" existed in that city, and that "the urgency of the case and the present anxiety of the citizens will justify" the stoppage of all intercourse between the cities. On August 31, 1795, the governor issued his proclamation, "with a sincere regret for the unhappy occasion," prohibiting for the term of one month, or until such prohibition shall by proclamation be lawfully removed, all intercourse between the said city of Philadelphia and the said city of New York and the said town of Norfolk, and any place or places within five miles thereof, respectively, as well by land as by water; the authorities of Philadelphia were directed,

> "with all possible vigilance and lawful authority and power, to guard the various avenues or entrances into the city of Philadelphia by land and water, so that any person or persons having been in the said city of New York or the said town of Norfolk within the space of ten days, and attempting to transgress the said prohibition by approaching nearer to the said city of Philadelphia than five miles, shall be forthwith remanded to the place or places whence such person or persons respectively came."

On the 4th of September the New York board of health protested against the proclamation, and condemned the Philadelphia board for obtaining information through other channels than its own official records. The chairman of the health committee of the New York board, John Broome, wrote to the chairman of the Philadelphia board, Richard Zittermary, September 4, alleging:

> "The committee are so thoroughly persuaded that any information the inspectors of the board of health may have received which can justify the proclamation in question is unfounded that they have directed me to request from you, as chairman of the board of health for the city and liberties of Philadelphia, copies of the several letters as far as respects such information, together with the names of gentlemen who wrote them, and to express a hope that on future occasions the inspectors of the board will do them the justice to believe them full as capable and equally disposed with any individuals of this city to give every necessary information on a subject so interesting to the happiness and interests of both places.

The Philadelphia board refused to comply, as it would be a breach of confidence.

The governor of New York, Hon. John Jay, addressed a letter to the Medical Society of New York, September 4, asking for information in regard to the alleged contagious disease. He said: "The proclamation, by exciting alarms and apprehensions throughout this and neighboring States and in foreign countries, naturally tends to produce embarrassments to the commerce of this city, and to interrupt that intercourse with the country which is at all *times necessary to the convenience* and interests of both." The Medical Society, through its president, Dr. John Carleton, acknowledged the prevalence of a fever in low situations having an easterly exposure, with virulent symptoms which characterize fevers of the malignant sort. But though "the sensibility of the public mind on a subject of this nature, giving reality to apprehension, converted the necessary efforts for security and prevention into sources of fear and terror," the collective opinion of the society was that the fever was slightly, if at all, contagious, and was the same that occurred annually, having been rendered more malignant by local causes.

Governor Jay communicated these facts to Governor Mifflin, but the proclamation was not modified, and expired by limitation.

The public feeling in New York in regard to the proclamation of non-intercourse with Philadelphia appears in the following extract, from the *Daily Advertiser*, New York, September, 7, 1795:

"The prohibition of intercourse between this city and Philadelphia is a proceeding very singular, and deserves severe animadversion. It is a *measure that, to say the least,* wears the aspect of a most unfriendly disposition, as it *naturally tends to create unnecessary* fears abroad, which may occasion an order for our vessels to perform quarantine in foreign ports to the great injury of our trade.

"It seems the board of health of Philadelphia reported to the governor the existence of a contagious disease in this city *on the* authority of private letters, without even writing *to our* health *committee* for a state of facts. This is a most extraordinary proceeding, when the reports of our committee have repeatedly informed the public that the epidemic now prevailing exhibits no decisive evidence of a specific contagion. Scarcely *in one instance* has an attendant on the sick taken the disease.

"This fact was known to the board of health and the governor of Pennsylvania, and yet the *world* is to be alarmed for the safety of Philadelphia, when the disease has not proved contagious enough to *occasion any general alarm in* New York. The disease is almost wholly local. Most parts of the city are entirely free from it. But one person died yesterday, and not more than five or six dangerously ill. In the name of common sense, must all the business of New York be impeded by the *ill-timed inquiries of Philadelphia?* Is this a generous *return for* $5,000 raised *in* New York to assist the suffering poor of Philadelphia during their great calamity? When dangers become real, will *not* the citizens of New York be alarmed? Let the public judge. The epidemic of *this city is not a new disease. It is a disease that* occurs more or less at this season *in most of the* sea-ports. It is not the disease that should occasion alarm, but its contagion, which depends mostly on local causes."

This protest of the New York papers seems very familiar reading in our time, and equally so the response of the Philadelphia correspondent of the *Daily Advertiser*. He writes, September 10:

"Our New York brethren, it seems, are very *angry at the* proclamation of our governor prohibiting the intercourse for one month, unless after ten days' absence, *and complains* that our board of health advised it, without writing to New York to obtain a state of facts. That they should be angry is very natural, but that the suspension of direct intercourse, for the present, take place, is no less just. The proclamation, however, was *not issued before sufficient* information was obtained of its necessity, though this did *not* come from the *committee of health*. On the *contrary*, every measure had been previously taken to have a true knowledge of the facts, and the result was that an epidemic fever raged in the upper part of the city, *of which* numbers died; that it was highly malignant, consequently there was every just reason to apprehend its introduction into *this city*, and self-preservation justified the measure adopted: The citizens of New York should *recollect that the first alarm* of this fever originated full six weeks since, and that it was not *until* two weeks past that the committee would even allow the existence of any fever than the *common one of the season*; that at least, when increasing mortality could no longer *justify an attempt to conceal* the truth, they did acknowledge the existence of an epidemic, but asserted its confinement to the upper party of the city. This was enough of itself, as it is ridiculous to suppose that a fever *which had* been gradually increasing for three weeks was not spread *by contagion. The yellow fever of 1793* in Philadelphia was also chiefly confined for the first month to the neighborhood of its original appearance; the rest of the city was never more healthy, as is now rung in our ears *constantly with* respect to New York. But how did this fever of Philadel*phia spread, and how is that now* spreading at New York? We all know how positively the Baltimore committee denied last year that the yellow fever prevailed there: it was the bilious fever, fall fever, prevailing fever, *unknown fever*, every name but the right one was given it; thus it is at New York. *It appears that* both our port physicians wrote for the true state of the facts, and *instead* of these we have a *lengthy disquisition upon the origin of contagion*. . . . The citizens of New York should *recollect that a burnt child* dreads the fire, and that though the intercourse is prohibited, yet that humanity is joined with our precaution, and so far from firing upon their stages, denying the passengers any food but at the point of a pitchfork, and obliging them to sleep in the woods, *nay even mixing the healthy with the* sick upon Governor's Island, all of which were done to those from *Philadelphia in 1793*, the people of New York are merely prevented from coming nearer to this city than five miles, where they may meet with every accommodation and transact their business by letter."

Richmond and Petersburg, Va., quarantined against Norfolk. At a meeting held in Richmond, August 27, 1795, it was resolved:

That the committee appointed at a late meeting for the purpose be *immediately authorized to* engage *a proper* vessel and guards, and to lay such restrictions on the entrance of passengers, carriages, and goods, by land or water, into this city from Norfolk, or any other place infected with the pestilential fever now raging at Norfolk, as to them shall appear *necessary*."

Owing to the death of a person at Petersburg, who came from Norfolk sick with the fever, it seems that "guards are now placed out, to stop all persons coming from Norfolk to this town by land or water."

(To be continued.)

THE "BRITISH MEDICAL JOURNAL."—The success of the *British Medical Journal* has been almost phenomenal. Dr. Withers Moore, the past-president of the Association, recently expressed the *opinion that* such success was largely due to the management of the able editor, Mr. Ernest Hart, who, he said, had brought *The Journal* to such a pitch of excellence that it was a sort of model journal for all the medical journals throughout the world. The staff is a large one, and includes Dr. Dawson Williams, who is an able assistant to Mr. Hart. Mr. Fowke, the general secretary, is said to have great business and executive capacity *The revenue* from advertising during the last year was $70,000, a very respectable sum, and quite an assistance to a journal of any description. In addition, the sums received for subscriptions and sales of *Journals* amounted in the aggregate to over $80,000 during the year. The *total* annual revenue is now about $155,000.—*The Canadian Practitioner.*

ANOTHER MEDICAL PRINCE.—At the University of Edinburgh, the medical commencement was held during the first week in August. Among those who received the degree of bachelor of medicine was an Indian prince, Sir Bagh[illegible]at Singh Jareja, the Thakore Sahib of Ghoudal. He is said to be the first native prince of Hindustan to acquire that particular degree, or any other Scotch medical diploma. His subjects purpose to signalize the *unusual event by* erecting a statue to *their ruler*, in his capitol in Ghoudal, in which the newly made Medical Prince will appear in the gown *and* hood of his degree, worn over his full native costume.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, SEPTEMBER 24, 1892.

INTESTINAL ANTISEPSIS.

In view of the greatly extended scope and the added accuracy in prognosis with which surgery and midwifery have been, almost recently, endowed, comes the consideration of the possible utility and value of similar methods in other branches of medical science. After passing such prominent landmarks as the specific action of quinine in malaria and the salicylates in rheumatism, probably the intestinal canal offers the widest field for research. The lines upon which procedures may be laid against intestinal parasites are: *first*, the mechanical method, or that by evacuants; *second*, the antiseptic, or direct destruction and *third*, the neutralizing, or an antitoxic disposal of the ptomains produced in the canal. Calomel, for instance, may fulfill all the indications, while naphthalin could be placed only among antiseptics. FURBRINGER and BOUCHARD have studied the production and destruction of such intestinal poisons. BOUCHARD has classified intestinal antiseptics as those that are freely soluble, those that pass into solution with difficulty or remain insoluble, and lastly, those that permit of chemical change into new compounds having special advantages. Phenol, calomel and salicylate of bismuth may be severally accepted as examples of these divisions. This writer has especially maintained that of these the insoluble compounds are most useful. According to his reasoning, the best results are to be obtained from a finely-pulverized insoluble drug, that may act throughout a long distance, and one administered in often repeated small doses.

The experimentation of ROSSBACH with salicylate of bismuth would strongly strengthen the theoretical efficacy of an antitoxic treatment.

That the value of the treatment of intestinal diseases with antiseptics is not yet established, may be judged from a review of recent experiments on the bacteriological condition of the digestive tract and of the fæces during health and disease. While SALKOWSKI shows a marked decrease in the number of colonies incident to the administration of chloroform; and while FURBRINGER shows somewhat irregular results, but results which, in the main, give from five to twelve thousand colonies less per gram of fæces, with than without the administration of naphthalin and calomel, STERN, in a very careful and complete investigation, apparently overturns previous conclusions.

STERN conducted his experiments upon a recently approved method. As a test bacterium the *B. prodigiosus* was employed. This microörganism offered peculiar advantages. It is innocuous, has a resisting power similar to the typhoid bacillus, can live at body temperature and in a slightly acid medium, and upon the plate, is easily recognized by its color. The trial patient was put upon a special diet. When the bowels moved an examination for *prodigiosus* was made, the result being uniformly negative. Then an ample quantity of prodigiosus culture was administered and after two hours followed by the antiseptic in question. This was continued at regular intervals until the end of the experiment. Calomel and naphthalin in 25 grain doses showed no influence upon the appearance and disappearance of the *prodigiosus* colonies from the intestine. Camphor, chloroform and iodoform likewise gave negative results. The great care in the manipulations and in the tabulation of the results, certainly entitles these experiments to be considered reliable; but their value, as the author himself admits, is not conclusive. On the one hand, in spite of the fact that the *B. prodigiosus* offers a similarity to *B. typhosus* yet it is hardly reasonable to assume that the conditions within the intestine are the same for the saprophyte and the parasite. On the other hand, an antiseptic may give one reaction to a medicament in artificial media, and another, quite different reaction in the intestinal tract.

So far as making determinations for the pathogenic bacteria themselves many obvious difficulties at once render the subject impracticable because animals are not available. What would be invaluable data from experiments on man are entirely beyond our reach.

The demonstration of a few thousand colonies, more or less, of entirely harmless saprophytes in the intestine after the administration of an untried drug cannot be taken as sufficient reason to lay aside a line of treatment that has so many theoretical and clinical advantages. The theory is that known anti-bacterial drugs, when introduced into the digestive tract, there exert their antiseptic properties.

BAUMANN measures the activity of albumen decomposition by the amount of iodol, skatol and kresol produced. For pathogenic bacteria, the severity of the general symptoms should be in direct ratio to the amount of ptomains produced, and therefore indicate their *quantity* and *quality*. That the general symptoms of such diseases as cholera and typhoid are modified by intestinal antiseptic treatment, is evidence that some influence has been brought to bear upon the intestinal contents. That the general mortality from typhoid fever in the Paris hospitals was reduced from 35 per cent. to 18 per cent. by the use of salol and chloroform, besides the advantage of this method of treatment in minor cases of gastritis and gastro-enteritis, is still ample enough proof that antisepsis in the intestine is not without a purpose.

CHOLERA.

Since our last issue a very few cases of cholera have been developed in New York and its vicinity, but in each instance the physicians in attendance with the coöperation of the public health authorities have been able to prevent any further spread of the contagion. We have in this a full and complete proof of the value of quarantine as a protective measure against the introduction and spread of this disease.

This epidemic has shown to the world that the researches of scientific physicians have developed a positive knowledge of the cholera poison and of its method of spreading from one individual to another. That it is solely through an introduction of the poison into the alimentary canal, and is neither inhaled nor absorbed through the skin. Hence it is, that the infection is always from the use of a cholera contaminated water or food supply. We now know that the comma bacillus is able to live for a considerable, perhaps an indefinite length of time in water that is impregnated with organic or vegetable matter.

On account of its sponge-like absorbing powers, milk is one of the most frequent sources of the infectious poison, because of its almost universal use as an aliment by infants and children.

Dr. Shakespeare, of Philadelphia, has made most critical observations of the cause, course and spread of the disease, from which he formulates two laws bearing upon its spread, viz.: (1) The tendency to infection varies exceedingly among individuals, and is with the majority small. (2) Disturbed conditions of the digestive apparatus greatly increase the susceptibility of an individual, and render him more liable to an attack after exposure to the infection. From which he teaches that a healthy stomach secreting normal acid juices, is capable of destroying this infectious bacillus. If, however, this living infectious bacillus escapes beyond the lower end of the stomach and passes into the small intestine, the contents of which are alkaline, multiplication with enormous rapidity takes place, and the disease is established.

From which we learn that certain acids destroy or render the comma bacillus innocuous. Hydrochloric acid, taken in small doses during or after meals, will add to the antiseptic powers of the gastric secretions. Irregularities of diet, alkaline drinks, loss of sleep, emotional excitement, fear, mental depression, and every disturbing influence, should be so far as possible avoided, as they weaken the powers of resistance that should naturally exist in every healthy individual.

These conditions will not in any instance, in and of themselves produce cholera, but they do render the individual so susceptible, that if exposed by the passage of the infectious bacillus into the alimentary canal, an easy victim to its virulence. The positive knowledge of physicians as to these facts should cause them to faithfully instruct all health boards and public officers in their duties in enforcing upon the people the extreme importance of absolute quarantine measures in every case of cholera; of the vital necessity of a pure, uncontaminated water supply, and of attention to the preparation of food. Special watchfulness should be exercised over the food and drink of children.

Every school, public and private, should receive the practical attention of a physician, who should formally talk during a school hour to the assembled children and teachers of their duties in this regard.

This should be done with much care and tact, so as not to create a feeling of fear, or mental anxiety, but to produce a sensation of security, rest and assurance of safety for those who follow the doctor's directions. These directions are neither a hardship or a task so severe as to be difficult to carry out. The children should be taught the danger of dirt, that filth and dirt cause sickness; that sickness means pain, suffering, misery, hard times, less education, poverty and poor living; that dirt conduces to a lack of self respect and promotes bad morals; that this cholera epidemic, like every other cholera epidemic, was generated, born in filth, spread through the medium of filth and now threatens us through impure water and improperly prepared food, and the handling of dirty substances; that absolute cleanliness of person, of houses and grounds, pure water and wholesome freshly prepared food are a combined bulwark and fortification that is strong to resist an attack of this insidious enemy.

The use of hydrochloric acid diluted as a drink meals, and the avoidance of other drinks comme itself most highly as a prophylactic agent. A remedy referred to by Dr. Stewart, of Philadelphia, that might be used where it is suspected that infection might occur, is hydronaphthol. *This is a* remedy that is valuable in cases of intestinal disturbances of various kinds, which are induced by fermentative processes. Hydronaphthol may be given as a prophylactic in doses of from three to five grains, largely diluted in water, three to five times a day. Hydronaphthol is almost a specific in the treatment of dysentery, and is a valuable agent in all cases of enteric disease. Peroxide of hydrogen is another remedy that will no doubt be of great value in the treatment of cholera. It is all important that the prodromic stage should be recognized and treated as cholera.

PIPERAZINE IN GOUT.

The popular knowledge in regard to the new "gout-water," containing piperazine, is spreading, and laymen in the horse-cars have been overheard discussing the merits of the water. But it is not yet so widely understood that there are other forms of the drug in addition to the aqueous solution of the hygroscopic crystals: for example, the *Notes on New Remedies* in its Berlin letter, informs us that the chemists have been enabled to produce tablets of piperazine. These compressed tablets contain the ordinary daily dose of 15 grs. They are easily disintegrated and dissolved in water, a manifest convenience in the case of travelers and vacation seekers. A granular effervescing powder has also been produced: in this form, the drug is said to be more palatable—although the crystals should be nearly tasteless—and the patient is led to imbibe more freely of water than he otherwise would—a point which is helpful in bringing out the best effects of the piperazine treatment.

Dr. Schweninger, the well-known medical friend of Bismarck, has recently made known his experience with the drug in over one hundred cases. He states emphatically that piperazine has given relief to cases of both acute and chronic gout to an extent that has been an agreeable disappointment. No remedial substance has done so much for gouty patients, in many years of trial of many remedies, as has this new product. He considers it "an exceedingly valuable addition to our treasury of medicaments." It has succeeded in cases where "all other remedies" have been tried in vain. The relation of piperazine to uric acid has been stated in the following terms: "It has the power of dissolving twelve to fourteen times as much of that acid as lithia will dissolve."

One important point in the use of piperazine for chronic gout is regular and persistent dosage. The remedy cannot be pushed, neither can it with advantage be experimented with in a haphazard way. It requires considerable time to dissolve out the uric acid from the system, even longer than is required to quell the painful symptoms of the disease.

it

of

PAN-AMERICAN MEDICAL CONGRESS.

The Committee on Organization of the Pan-American Medical Congress will issue the preliminary announcement of the Congress within a few weeks. This announcement will show that the organization has been perfected in almost every colony and country of the Western Hemisphere. The local medical societies in each of the constituent countries are made auxiliary to the Congress, which will be held in Washington, D. C., September 5, 6, 7, 8, 1893.

Dr. Reed, of Cincinnati, Secretary-General of the Congress and Chairman of the Committee on Organization, announces that after extended correspondence between himself and Dr. Maragliano, of Genoa, General Secretary of the International Congress, the date of the Rome meeting has been finally and definitely set for September 24, of next year. This gives an interval of sixteen days between the Washington and the Rome meetings, during which time an easy trip can be made from the former to the latter city. It is possible that a steamer may be chartered direct from New York to Rome.

EDITORIAL NOTES.

Keeley's Lawsuits.—Dr. Keeley has concluded to part with some of his golden gains to the legal fraternity of London. He has entered libel actions against the *Lancet* and the *Press and Circular*, in order to punish those journals for calling him a mischievous quack and inducing the friends of temperance to withdraw their partly promised support. The *Press and Circular* refused to publish Dr. Keeley's letter of vindication or explanation chiefly because the writer advanced no proof corrective of the "bad impression created by the almost universal condemnation of the so-called cure in the United States." Dr. Keeley is urged by these journals not to delay his actions for libel, and they promise to show him up.

Ownership of Prescriptions.—A recent trial in a Detroit court resulted in placing the ownership of prescriptions in the hands of the patient and not in those of the pharmacist. Testimony going to show that druggists everywhere regard the prescription as their rightful property was excluded, on the ground that the patient has the highest claim to the written formula.

Prize on Infant Therapeutics.—A bequest of Dr. Henry Roger, late of Paris, will put the French Academy of Medicine in possession of a fund, yielding one hundred dollars per annum, to be devoted to the purposes of a five-yearly prize. An award of $500 will be made for the best essay on the medical treatment of children.

An Anti-Cancer League.—Dr. Verneuil, of Paris, is said by the *Medical Press and Circular* to be the moving spirit of an association of prominent medical men, whose object is to attack the subject of cancer in concert and from all directions. The program has been devised with the utmost liberality by M. Verneuil, and he has succeeded in obtaining the cordial support of many of the best of his compatriots. Prizes and grants of substantial assistance will be made whenever deserved, and published records of work performed will be provided for whenever any advance shall have been made. Membership in the League has been fixed at about four dollars per annum; while sixty dollars will constitute subscribers to life membership. All that is needed, therefore, to ensure success, seems to be an active sympathy on the part of the profession which will bring into the movement a large number of working members, and of non-workers as well, all actuated with a zeal to overthrow cancer. There will be a small body of officers; as for example, there will be a central committee with a medical, and a surgical, and a general secretary; a similar officer will represent the department of experimental and regional pathology; also a treasurer. The coöperation is desired of all pathologists, clinicists, biologists, microbiologists and veterinarians. All explorers and geographers will be invited to obtain facts bearing upon racial and climatic peculiarities in the distribution of the disease.

It is expected that if the work moves along conformably to the plans laid down by M. Verneuil, a rich harvest of facts will be reaped, and there will be eventually congresses held upon the subject, and discussions organized upon all the causal and preventive questions therein comprised.

There is no obstacle against the formation of other Leagues in other countries, along similar lines of activity, and a cosmopolitan aspect might be added to the work of the Parisian committee, if a goodly number of large cities should volunteer to join in the same crusade against a foe that has recently been growing in strength.

The North Carolina Board of Health.—The *Bulletin* of this State Board contains a notice of the great loss "the old North State" has sustained in the decease of Dr. Thomas Fanning Wood.

The following changes in the *personnel* of the Board are announced to have taken place in consequence of Dr. Wood's death: "At a called meeting of the North Carolina Board of Health held in Wilmington, on September 7, 1892, Dr. George Gillet Thomas, Wilmington, N. C., was elected as a member of the Board to fill the unexpired term of Dr. Thomas F. Wood, deceased. Dr. Richard H. Lewis, Raleigh, N. C., was elected Secretary of the Board, and to him all communications should be addressed after October 1, 1892."

SOCIETY PROCEEDINGS.

American Association of Obstetricians and Gynecologists.

Fifth Annual Meeting, at St. Louis, Mo., Sept. 20–23, 1892.

Dr. George H. Rohé of Catonsville, Md., read a paper upon

THE RELATION OF PELVIC DISEASE TO PSYCHICAL DISTURBANCES IN WOMAN.

The author pointed out the frequency with which bodily conditions influenced mental states. Thus a torpid condition of the intestines, Bright's disease, putrefactive processes in the intestinal canal, etc., might give rise to melancholia and other disorders of the mental functions. It is not irrational to suppose likewise that diseases of the female sexual apparatus would have a not inconsiderable influence in the production or perpetuation of mental disorders. As a contribution to the knowledge of the subject the following report was submitted:

In a hospital containing 200 insane women, 35 were subjected to vaginal examination and 26 found with evidences of pelvic diseases. In 18 of these the uterine appendages were removed with the following results:

Sixteen recovered from the operation and two died. Of the 16 recovered, three have been discharged from the hospital completely restored, both physically and mentally. In 10, considerable improvement followed the operation in both physical and mental conditions, and in 3 the operation was of too recent a date to allow any definite expression of opinion.

The mental disorder present in the 18 cases was melancholia in 6 cases, simple mania in 1, puerperal mania in 4, hysterical mania in 1, periodic mania in 2, hystero-epilepsy with mania in 1, and epilepsy with mania in 3.

The author basing his opinion upon his experience, concludes as follows:

"The facts recorded demonstrate first: that there is a fruitful field for gynecological work among insane women; second, that this work is as practicable and can be pursued with as much success in an insane hospital as elsewhere; and third, that the results obtained not only encourage us to continue in the work, but require us, in the name of science and humanity to give to an insane woman the same chance of relief from disease of the ovaries and uterus that a sane woman has."

Rufus B. Hall, M. D., Cincinnati, Ohio, read a paper entitled

A CLINICAL REPORT OF GALL BLADDER OPERATIONS.

He reported 7 cases, all of the gall bladder operations that he had made. In three of which the common duct was obstructed from 3 to 7 and 9 weeks respectively. The case with obstruction for 3 weeks recovered from the operation. The case with obstruction for 7 weeks had gall stones for 3 years before operation and at the time of the operation had a stone impacted in the common duct, and malignant disease at the head of the pancreas and obstructing the common duct. The case with obstruction for 9 weeks had a stone so firmly impacted that he had to incise the common duct for its removal. The three cases were in extremus at the time of operation from the long continued cholæmia. The cases with obstruction for 7 and 9 weeks died from exhaustion on the 3rd and 6th days after the operation. The remaining cases in which the cystic duct was obstructed recovered, making five recoveries and two deaths. With the light of his experience the author would hesitate to advise an operation in cases where there had been complete obstruction of the common duct for 7 to 9 weeks. The power of recuperation in such profound and continued cholæmia is so feeble that we can hardly hope for other than a fatal termination. The author of the paper is strongly inclined to the opinion that there is a causative relation between gall stones and malignant disease in and about the gall ducts and head of the pancreas. He thinks that the long years of continued irritation from the presence of gall stones and the consequent repeated attacks of hepititus favors the development of malignant disease in and about the gall ducts. He urges early exploration in obscure hepatic disease of a number of years' standing, even if a positive diagnosis of gall stones cannot be made, and cites a case in which he removed 91 gall stones under similar circumstances. In that case the patient had pain in the region of the gall bladder and liver but no other signs of gall stones. If early operation was made there would not be so many cases of obstruction of the common duct with the high mortality following that complication. If all of the cases operated upon where the common duct was obstructed could be tabulated, the mortality would probably be very great. On the other hand, the operation in cases where the common duct is not obstructed, the mortality is very small. These facts should be sufficient to warrant early exploration.

Honors to Huxley.—The members of the medical profession will receive with lively satisfaction the announcement of the appointment to a seat in the Privy Council of Professor Huxley.

SELECTIONS.

The Test for the Comma Bacillus.—In view of an impending epidemic of cholera in this city, and probably in the greater portion of the other cities this side of the Atlantic, I desire to give your readers the usual method of examination of dejecta of suspected patients as practiced in the Bacteriological Institute at Berlin last summer.

The articles necessary for the examination are: 1. A microscope with Abbe's condenser and the oil-immersion system. 2. A solution of fuchsin 1 gm. (Rubin) in 90 cc. distilled water and 10 cc. alcohol. 3. A few pipettes, glass rods, object-glasses or cover-glasses, and slides. 4. A few platinum wires melted or soldered to the end of glass rods. 5. A few hollow slides. 6. Ten to twelve glass plates or glass panes about 12 ctm. long and 9 ctm. wide. 7. About a dozen ordinary flat plates. 8. An alcohol lamp, or gas being preferable, a Bunsen burner. 9. A number of test-tubes with sterilized gelatine. 10. A number of test-tubes with sterilized nutrient bouillon. 11. A few Erleymer's glasses, about one-third filled with 1 per cent. pepton solution; 1 gm. pepton, 0.5 gm. chloride of sodium, 100 gms. distilled water. 12. Concentrated sulphuric acid.

The dejecta of suspected patients are scattered in as thin a film as possible on a plate, and this is carefully examined with the aid of a platinum wire for a mucous flake, "Schleimflocke," which is laid on the edge of the plate and isolated.

From this we take a piece the size of a pin's head, and sterilize a platinum loop (by drawing it through a Bunsen burner), and then rub it on a cover-glass until it is evenly divided; then remove all superfluous material by pressing another cover-glass over it, and allow it to get air-dry.

Then draw it three times through a Bunsen burner in the same manner as we proceed in the examination of sputa for tubercle bacilli, and by means of a pipette add a few drops of the fuchsin solution for about one to two minutes to the cover-glass, and then wash it off in distilled water. Then add a drop of water to the cover-glass, lay it on a slide, and examine it with the oil immersion system.

If we wished to preserve the specimen we could, after staining with the fuchsin solution, wash off the excess of stain with distilled water, and allow it to get thoroughly air-dry, then add some Canada balsam.

In some cases called "foudroyant," where the intestinal contents have a colorless or pale red color, with slimy (mucous) flakes or with a flour-soup mass, we will frequently find, especially, however, in the reaction period with cases running a slow course, no mucous flakes, but large quantities of blood. Here there are, besides cholera bacilli, large quantities of other microörganisms, and sometimes only the cholera bacilli sparingly, so it is advisable, to render a diagnosis absolutely positive, to add to microscopical examination the examination by the aid of "cultures."

Cultures can best be made in "hollow slides" by smearing the border with vaseline, then bringing a small drop (from a platinum loop) of sterilized bouillon into this hollowed groove of the slide, and inoculating this latter bouillon with the smallest possible particle of the suspected mucous flake. The cover-glass is carefully laid on the vaseline, which serves to render the groove air-tight, and also prevents the evaporation of this drop of sterilized bouillon, which is then laid aside in a temperature of 20° to 22° Celsius. The room can be heated if the temperature of the air is below this. It takes about twenty hours to have the bouillon turbid, and this slide (hollowed, containing the infected bouillon) can be examined with the oil-immersion without disturbing the culture. The best place to examine is the border line, and even if but few cholera bacilli were formerly present, they grow so rapidly that they will be easily recognized by their curved shape.

Culture Method by Schottelius: Take 100 to 200 cc. of the suspected dejecta from intestinal contents, and place them in a beaker glass containing 250 to 500 cc. of mild alkaline meat bouillon, and mix thoroughly; then let this mass stand about twelve to twenty-four hours at a temperature of 30° to 40° Celsius. After this time the cholera bacilli have usually increased in numbers, and are found on the upper layer of the fluid. By introducing at the upper layer a platinum loop, and taking out a small drop (about the size of a lenten seed), and rubbing it on a clean cover-glass, we allow it to dry thoroughly (air-dry); then draw it three times through a flame to fix it, and finally stain, as previously described, with the fuchsin solution.

Post-mortem Tests: To examine suspected intestinal contents I open the abdominal cavity carefully and ligate, with aid of two stout cords or twine, a piece of the ileum (about 3 to 4 centimetres in length), well filled with fecal contents, near the cæcum. It is well to apply a ligature close to the upper ligature, and another below the lower ligature, and cut between the two ligatures, so that the intestinal contents will not be spilled in the abdominal cavity and prevent the completion of the autopsy. It is well to cut out a piece of the intestine, about 3 to 4 centimetres in length, from the upper portion of the ileum, and to lay the excised portions into ordinary water until ready for use, *i. e.*, examination of contents. The method is the same as has been described, *i. e.*, take a small piece of flocculent mucus, about the size of a pin's head, and examine it. Gelatine stroke and stick cultures, and also potato cultures, can be made for examination. They also grow on blood serum and agar.

A practical point is the following: Koch found cholera bacilli in the water of an East Indian tank. But it is the rule that the cholera bacillus does not develop very much in our ordinary water, owing to the presence of other bacteria which easily destroy the cholera bacillus; but they do develop marvellously in sterilized water (water free from bacteria); so, for instance, soup is an elegant medium for their development.

Human beings are usually infected through the mouth—*i. e.*, through food, etc.—and it is found that if the stomach is partly filled and has sour reaction (gastric juice), the latter acts as a barrier to the infectious material.

Cholera bacilli require for their growth a mild alkaline nutrient medium, and are very sensitive regarding mineral acids.

By adding 0.07 to 0.08 per cent. of muriatic or nitric acids to a neutral nutrient solution the growth of the bacilli was stopped. This statement is found in Günther's Bakteriologie, p. 210, and is made by Kitasota.—Louis Fischer, M.D., in *N. Y. Med. Record*.

It is a noteworthy fact that not a single case of small-pox occurred during the year 1890 in the British Army. If this be not evidence of the protection afforded by re-vaccination against a malady once so common—and still disastrously fatal in armies where this precaution is not vigorously enforced—then logic and reason are mere accomplishments.—*Medical Review*.

Unfit for Colonization.—An agent of Baron Hirsch reported that the Jewish peasants in the Odessa district are so degraded that the Argentine Republic would not allow them to be sent to the Jewish colony there, and that it is therefore expected that they will be sent to the United States.

BOOK REVIEWS.

A Manual of Diseases of the Nervous System. By W. R. Gowers, M.D., F.R.C.P., F.R.S. Second edition, revised and enlarged. Vol. 1, Diseases of the Nerves and Spinal Cord. Philadelphia: P. Blakiston Son & Co.

The work of Dr. Gower's in its first edition has been so long before our readers that we do not think an extended and critical review of these pages is needed at this time. The title page says that this second edition is revised and enlarged; a comparision with the older work shows that indeed it is a new edition and not a reprint, as is too often the case.

A careful examination shows that the author has brought to his task a wealth of clinical experience and such a profound grasp of the philosophy of medicine, that his work easily ranks first among the English treatises on diseases of the nervous system.

The typography of this, the American edition, is only fair, the paper is poor, and the cuts are most of them blurred and indistinct. It is to be regretted that so valuable a work does not come to us in a better dress.

MISCELLANY.

S. D. Gross Monument Fund.—Dr. John B. Roberts, Treasurer of the American Surgical Association, acknowledges the receipt of the following contributions to the Gross Monument Fund. Contributions are hereafter to be sent to the Gross Monument Committee of which Dr. J. R. Weist, of Richmond, Ind., is Chairman.

Dr. Douglass Graham, Boston	$ 5
Dr. Solen Marks, Milwaukee	20
Dr. L. C. Lane, San Francisco	50
Dr. A. H. Plummer, San Francisco	20

Dr. T. W. Huntingdon, Sacramento	1

Dr. C. F. McGahan, Chattanooga, Tenn., has removed to Aiken, S. C.

Dr David Stainrook Booth died at his home in Marissa, Ill., September 10, aged 64 years.

Tri-State Medical Society.—The regular annual session of the Tri-State Medical Society of Illinois, Iowa and Missouri will convene at Kahoka, Mo., Tuesday, Oct. 4, 1892. Members of the profession are cordially invited to be present.

1. Roll call; 2. Reading of minutes; 3. Proposals for membership; 4. Report of committee on credentials; 5. Resolutions introducing new business; 6. Selection of next place of meeting; 7. Reports of special committees; 8. Report of treasurer; 9. Election of officers; 10. Miscellaneous business; 11. Reading of papers.

List of papers:

1. Uterine Fibroids and their Treatment, by J. H. Beucler, M.D., Revere, Mo.
2. Dietetic Treatment of Dyspepsia, by J. R. Hollowbush, M.D., Warsaw, Ill.
3. Sanitary Science *vs.* Epidemics, by Geo. P. Neal, M.D., Ft. Madison, Iowa.
4. Thaumaturgy in Medicine, by J. M. Shaffer, M.D., Keokuk, Iowa.
5. Intussusception, by J. H. Coulter, M.D., Summitville, Iowa.
6. A Case of Purulent Pleurisy, by H. C. Young, M.D., Bloomfield, Iowa.
7. Professional Secrets, by W. R. Allison, M.D., Good Hope, Illinois.
8. The Physician and his Compensation, by O. F. Pile, M.D., Memphis, Mo.
9. Variations of Gestation, by T. C. Hays, M.D., Vincennes, Iowa.
10. The Hæmatozoan of Malaria, by J. Fred Clarke, M.D., Fairfield, Iowa.
11. Operative Treatment of Intra-Cranial Lesions, by C. E. Ruth, M.D., Muscatine, Iowa.
12. Obstetrics, by Calvin Snook, M.D.. Fairfield, Iowa.
13. The Physician as an Educator, by W. V. English, M.D., Keokuk, Iowa.

J. M. Ball, M.D., *Sec'y.*

The Mississippi Valley Medical Association will hold its eighteenth annual session at Cincinnati, Wednesday, Thursday and Friday, October 12, 13 and 14, 1892. The program is a valuable one, containing many of the most prominent names in the profession our country affords. It covers every department in medicine. The attendance will be unusually large, as Cincinnati is the centre of population of the United States. Not only the scientific, but also the social part of the meeting will be of the highest order. The interest of the Convention will be augmented by the meeting of the gentlemen interested in the Pan-American Medical Congress, also other bodies of medical men. Dr. Benjamin Ward Richardson has written his earnest desire to be present. The Association will be just in time and just in line for many of the gentlemen *en route* for the American Public Health Association in the City of Mexico. Among the many prominent gentlemen who are expected to read are the following: Dr. Hunter McGuire, Richmond, Va., President of the American Medical Association, the address on Surgery; Dr. Hobart Amory Hare, Professor of Materia Medica, Jefferson Medical College, Philadelphia, the address on Medicine.

C. A. L. Reed, M.D., President, *Cincinnati.*
E. S. McKee, M.D., Secretary, Cincinnati.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from September 10, 1892, to September 16, 1892.

By direction of the Acting Secretary of War, a board of medical officers, to consist of Lieut.-Col. Chas. H. Alden, Deputy Surgeon-General; Lieut.-Col. Geo. M. Sternberg, Deputy Surgeon-General; Lieut.-Col. Wm. H. Forwood, Deputy Surgeon-General; Capt. Wm. F. Carter, Asst. Surgeon, is constituted to meet in New York City, on October 3, 1892, for the examination of candidates for admission into the Medical Corps of the Army, and for such other business as the Surgeon-General may desire to bring before it. By Par. 9, S. O. 43, A. G. O., Hdqrs. of the Army, September 9, 1892.

Major Henry M. Cronkhite, Surgeon (Ft. Trumbull, Conn.), will proceed without delay to Sandy Hook, N. J., and take station at that place for duty with the Government employés thereat, under telegraphic instructions of this day from the War Department. This detail will continue [illegible]ing the encampment of civilians landed at Sandy [illegible] from infected vessels at quarantine in New York Ha[illegible] S. O. 123, Hdqrs. Dept. of the East, Governor's Is[illegible] New York City, September 9, 1892.

First Lieut. Ashton B. Heyl, Asst. Surgeon U. S. A., granted leave of absence for fifteen days.

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending September 17, 1892.

P. A. Surgeon C. T. *Hibbett, detached from* receiving ship "Franklin," and wait orders.

The Journal of the
American Medical Association

THE RELATION OF PHYSICAL VIOLENCE TO HERNIAL PROTRUSIONS THROUGH THE ABDOMINAL WALLS.

THE PHYSIOLOGICAL, PATHOLOGICAL AND MEDICO-LEGAL ASPECTS OF THE QUESTION.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY THOMAS H. MANLEY, A.M., M.D.,
VISITING SURGEON TO HARLEM HOSPITAL, NEW YORK.

Shortly after my advent into the active practice of my profession, a case came under my observation, in which, it was alleged that the patient, who then, had a large, inguinal hernia, sustained it, solely, through an assault. As the patient was a very old man—about 70, or 75 years old—in consequence of the castigation he had borne, in connection with the infirmities associated with the senile state, he was confined to the house, considerable part of his time, remaining in bed. After ailing for a month or two he died.

It is unnecessary for me here, to note the gross provocation which incited his assailant to belabor him; nevertheless, it is *apropos* and important, to state, that no inordinate violence was employed. The old man was hoeing by the roadside; when a man came along, driving cows to pasture, when one of them crouched her neck and bit off the leaves of a growing plant. For this, the old man ran after the animal, hitting her on the back several times with his hoe. The owner of the cows who was a middle-aged man, was carrying a birch switch in one hand, and becoming enraged, struck the offender with it several times; finally knocked him down and kicked him. There was no weapon employed, nor, any violence, other than would happen in any ordinary assault. The farmer unfortunately, was a thrifty, prosperous man and had accumulated some, few thousand dollars, worth of real estate; and hence, there was some fine picking for the lawyers. Civil and criminal suits were commenced, almost simultaneously; the unfortunate man, being first tried and condemned by the newspapers and then as a matter of course, adjudged guilty of felonious assault and sentenced to prison. He fared no better with the civil suit; for, such heavy judgments were brought in against his estate, that it required the practical sacrifice of it, to liquidate them. In this instance the basis of the whole case, rested on his hernia. It was sworn to, by the attending practitioners that the hernia resulted from the violence, borne in the altercation; that he suffered great and unusual pain, in consequence of the hernia; and, that it was the final cause of his death. No post-mortem was made to substantiate these allegations. I saw the case once in consultation and was confident, from a critical examination, that the hernia was an 'old pathological infirmity. Although I had had no special opportunities to acquire a special knowledge of the morbid anatomy of inguinal protrusions, at that time, yet I was convinced from the physical characteristics, that this one, that this man suffered from, was a very old one; and hence, my impression, that the whole proceeding from the beginning to the end, was unfair, iniquitous and scandalous; hence, I determined that should occasion ever offer, I would endeavor to prove to my own satisfaction, that the existence of a hernia dependent on a simple assault or ordinary violence is scarcely ever a possibility. The opportunity, came sooner than I expected; and now, after having examined and operated on nearly every species of hernial disease, I am able to say, *without any qualification* whatever, that hernia is *never* attributable to traumatism alone; unless, the violence be applied by some hard, heavy, sharp-pointed instrument or substance which either punctures or rents the abdominal wall; and that, when a hernia appears, after the application of ordinary force, it can always be demonstrated, that it had previously existed, the accident or injury being an incident only, in its evolution.'

Since then, in the event of injury, accidentally, or intentionally inflicted, the unscrupulous or vindictive, may make the presence of a hernia, the pretext for a criminal or civil action, and as the judiciary, must rely on surgical science, in a large measure, for such knowledge or information, as will render a fair and just decision possible, it behooves us, to give this subject of traumatic hernia, the searching and analytical study, the importance, which it merits.

This may be best accomplished, mainly in two ways. The first, is, by the grouping together, as far as possible, the isolated cases of a great many observers; in which, violence has seemed the predominating element, in the causation of herniæ; and secondly; by examining into the structural development of those canals or vents, through which the abdominal viscera escape; their normal, natural contour, and their abnormal, anatomical configuration. Surgical literature is rich, in extensive and valuable observations, by many of our most eminent and scientific authorities, in connection with the latter; but the literature of the former is scant. Whether, it is, because authors and practitioners failed to report their cases; or, that it was the accepted *dictum*; which was admitted without question, that physical force may in itself, suddenly cause hernia; I am unable to say. Or, is it to be ascribed to an unwritten, but nevertheless well established view, that physical force is but supplemental, in the etiology of traumatic hernia?

It is a matter of custom, with the laity, to attribute, in the majority of instances, their ruptures to various kinds of accidental injury; as strains, jumps, blows, falls and compression force, variously applied. But, how far physical force in itself, has been regarded, by surgical authorities as constituting a sole, or even predominating factor in hernial protrusions, is important to ascertain, while endeavoring to make an accurate estimate of violence alone in the disease.

In order to fully inform myself, in all those forms of hernia induced by physical force, alone, I made a thorough examination, of everything, which I could find, in one of most complete medical libraries in America.* Consulting all the works I could find, ancient and recent; on[1] general surgery,[2] medical jurisprudence and those devoted,[3] specially to the subject of hernia.

And, there, to my chagrin and disappointment, I was able to glean almost nothing. There, from the many eminent authors on medical jurisprudence, on hernia and surgery, I was unable to find a *single case* of purely traumatic hernia, recorded. Certainly, much was expected from those. of extensive military experience; those who have seen force applied in a thousand forms; particularly in the charge and in retreat, when horses, men and artillery tread and crush the disabled under them. In the explosions of shells and mines; when men are hurled, instantaneously, from their feet, in every direction; when limbs are blown off, internal organs ruptured, the body palsied, the brain and spine violently concussed; and when, from such commotion one or more of the special senses, as the sight, hearing, or speech is forever lost, we would indeed look for the appearance of hernia, as one of the most frequent of all sequelæ, to such violence and shocks. But, Baron Larry in his memoirs is silent on this subject; and, in our own exhaustive "Surgical History of a Civil War"; a war in which, it has been estimated that a million human lives were sacrificed, not a line can be found, on the subject of violence as a cause of hernia.

Sir Astley Cooper the greatest English authority of his time, in the most populous, the largest industrial and commercial centers of the world, is silent, on hernia of this species; so that, with practically very few exceptions, the authorities are barren on the subject.

The venerable Gross, was the only American author who vouchsafed anything, whatever, on it; when writing on hernia. He said, "hernia is sometimes the immediate result of external violence; as a *blow* or a wound, splitting or severing some of the component parts of the abdominal walls."

Spence denies physical force only, as a cause of hernia, by the laceration and giving way of structures as is seen by the context. He says: "Except in direct, penetrating wounds, protrusion from laceration of the abdominal wall, must be very rare; if it ever occurs." Hence, the popular term, "*Rupture*," so frequently employed to designate this disease, is an improper one, and likely to mislead, as to the true state of matters.

The vast majority of authors, although they divide the causes of hernia, into predisposing and active, they usually limit themselves to a consideration of the former; and, on the latter, speak only, in such a dubious undecided manner, that their opinions carry little value with them. There were quite a few authors on general surgery here quoted, who do not, even mention the subject of hernia. This is conspicuously the case, in one of our most recent text books.

The terrible mortality which attended surgical operations for hernia before the days of anæsthesia and wound cleanliness, probably had much to do with explaining the general dearth of knowledge of the etiology and of the various phases of morbid anatomy which constitute the ground work of all abdominal hernia. Paul Sègond in his admirable treatise on the surgical history of hernia, tells us, that, in those cases of reducible hernia operated on, in the pre-antiseptic times, death commonly followed, due to gangrene, erysipelas, tetanus, hæmorrhage and shock; which explains, why so many, when called to extend measures of relief, to those, whose herniæ depended, apparently on traumatic influences, neglected not only to operate, but to follow up their cases, by post-mortem examination, in the event of death.

From the foregoing, then, we can come to but one conclusion with reference to herniated protrusions developing, as result of physical force. I have neglected to make a general appeal to surgeons for information on this special feature of hernial etiology, but trust that the presentation of the subject, will be enough, to call forth from different sections of this country, and others whatever experience, those who have had the best opportunity to enjoy, can offer. The question should be so definitely settled, that hereafter, we should seldom hear of traumatism *per se*, ever giving rise to herniæ.

But, if force, in itself is disallowed as the only cause in producing a hernia, yet no one of experience can deny, that it plays an important *rôle* in hastening its full development: aggravating its conditions, causing strangulation; being a possible cause of laceration of the sac; of hæmorrhage, inflammation or gangrene of it.

I have never seen a case, in which there was proof, that a hernia was forced through any of the natural passages, by inflicted violence; among those who have been run over; who have been crushed in various ways, have fallen from a considerable height or sustained violent blows over any part of the abdomen.

Many have come under my observation, who have sustained mortal thoracic and abdominal lesions, in consequence of great and sudden force; after which, in different cases, have been discovered, rupture of the various solid and hollow organs. But no herniæ were ever associated with these ruptured organs. This, however, is not sufficient to prove that it may not ever occur; for it is only the experience of one; nevertheless, I have taken good care, to fortify it by an extensive review of the literature on the subject and hence, must conclude that a hernia is very rare at all events, under these circumstances.

A great many cases, however, will come under our care, in which the patient will tell us, that their hernia appeared for the first time, after a great strain, or violent muscular exertion; as lifting, gymnastic-exercises, and straining of various kind. They very naturally assume, that this temporary violence is the sole cause of their infirmity; that something has given way, torn through, or *ruptured*.

Many of them, on the most minute oral examination will deny that they even had a fullness of any description, whatever, in the herniated area. Their attention is first called to it, by the volume of the hernia; by pain or soreness over it. It may be, that some days elapse, before it is discovered, unless suddenly strangulated. Sometimes, the force applied, is so infinitisimal, that one would be inclined to deny it as a causative factor. As an apt illustration, I may cite the case of a woman, forty years old, in good, previous health, who was one day, out raking in her yard, when her rake fell from her hand to the ground. In stooping to pick it up, she said, she felt something give way, low down on the back. This was succeeded by colicky pain, great bodily weakness and vomiting. She was first treated, for intestinal obstruction, but, at the end of the first day, her true condition was recognized.

---

*Library of New York Academy of Medicine.

Thirty hours after she was first seized, I operated on her, for a strangulated, inguinal hernia. The bowel was thoroughly gangrenous and she died on the table, before the operation could be completed. Very many cases are being constantly met with, in which the strangulation is caused, by straining at stool.

Now, when it is apparent, that so little, insignificant force as that which so often causes a strangulation may increase the volume of a hernia one can easily conceive of a case, in which, on very moderate force, the application of it, being accidental or intentional,a hernial protrusion may appear, either strangulated or not, and after which, for malice or gain, the patient or his friends institute civil or criminal proceedings,against the individual or corporation,responsible for it.

Here then, is a supposititious case, in which several interesting questions may rise;—and I may say, in passing, that we may be prepared at almost any moment to deal with actual ones,when one of the first questions will be: was the injury a *causa sine qua non*, or a contributory incident only? The first, has already been answered, the second must be answered in the affirmative. For it may be laid down as a rule, that the application of physical force is commonly an active factor in effecting the full evolution of a hernia; or in aggravating the condition of one pre-existing.

The Effects of Physical Force on Pre-existing Herniæ; Or, on Those Pre-disposed to Hernia.—The injured may suffer as a result of violence applied directly over the seat of a recent, or an old, incarcerated hernia. If strangulation have immediately ensued, it may be alleged to have followed this applied force, or sometime later.

Certainly, the integument over a hernia will show the evidences of contusion, from kick or blows, in the same degree as those situated elsewhere; but, that one's life is actually imperilled by the imflammatory changes established in the tissues immediately contiguous with the hernia,must be conceded. In this instance, much will depend on the character of the hernia, itself; its size, situation and consistence. We can easily understand, why in an old epiplocele a considerable bruising might be borne, without any serious sequelæ. While, on the other hand, over a recently extended knuckle of intestine, much less contusion might be followed by serious results. It might be claimed that the hernia never appeared before the injury and that strangulation followed, solely, as a sequence of the inflicted violence.

It cannot be denied that there are numerous cases of strangulated hernia, in which the patient is totally ignorant of ever having any sort of hernial disease before his life was suddenly endangered. But, he may have had a visible protrusion, nevertheless, which in consequence, of it never having given him any pain; being of small size and covered by pubic hair, has escaped his notice. Yet, even assuming that there positively was none at the time of accident still there was the predisposing, anatomical congenital imperfection or defect of development.

In a case of incarcerated strangulated scrotal hernia, in which it is alleged that the sole provoking cause was direct violence, applied immediately over the fulness, can we, from the presence of the physical characters under our eyes, in operating or at post-mortem examination, determine whether the state of the tissues, is attributable to a traumatism; or to pathological changes? This is of very great importance to ascertain in a civil or a criminal case.

Judging *a priori*, one would naturally suppose that in these times of refinement and accuracy in diagnostic methods, that it would be a very simple matter to differentiate one condition from the other.

If a case were seen immediately after the injury, one might possibly, then and there be able to say whether the external appearances indicated violence.

The presence of discoloration of the integument and bloody extravasate into the loose connective tissues, with patches of ecchymosis would point to traumatism, but, this would be all. After serious inflammation commences in the sac, there is practically nothing, which will in any way, aid us, when discoloration is absent in, separating the pathological from the traumatic. In both, we will, after a very short time, find the skin and cellular membrane thickened, traumified and sensitive; the sac thick, turgescent and distended with a serous,or sero-sanguinolent fluid; the intestine, congested, inflamed or gangrenous. There is then, pathologically, no definite line, by which, a pathological strangulation, can be definitely identified, from one induced by violence, inflicted in any way whatever; short of a penetrating wound. One must, then always exercise great circumspection in many of these cases of injury, in the male or female; in which the groin, the scrotum or the labia are involved, if he would avoid mistakes in treatment, unnecessarily alarm the patient or magnify the importance of the injury. Three years ago I was called to see a young married woman; who while standing on a chair, hanging pictures, slipped and fell, her perineum coming astride the back of a chair. When I reached the house, I found two physicians in attendance. She had been anæsthetized; and taxis had been persistently employed, to reduce a large hernioid mass, in the right labium; but, they utterly failed; when, I was sent for. In examining the case, I found that what they were trying to reduce was a large hæmatoma. Now, in the male scrotum, this mistake is never likely to occur: because of effusion of blood into the tunica-vaginalis or the fascia-spermatica, extending up, to the external inguinal ring. An acute orchitis, complicated by an epididymitis and free cellulitis, with an œdematous, condition of the tissues, might, without a careful examination, be mistaken for hernia, after injury. In every hernial case, coming under our observation, in which violence is alleged, the most thorough and complete examination, is always imperative. In the course of examination, if we are in doubt, the most skilful and experienced surgeon, obtainable, should be sought for, to aid in assuring accuracy of diagnoapplied. But, how far physical force in itself, has been regarded, by surgical authorities as constituting a sole, or even predominating factor in hernial protrusions, is important to ascertain, while endeavoring to make an accurate estimate of violence alone in the disease.

In order to fully inform myself, in all those forms of hernia induced by physical force, alone, I made a thorough examination, of everything, which I could find, in one of most complete medical libraries in America.* Consulting all the works I could find, ancient and recent; on[1] general surgery,[2] medical jurisprudence and those devoted,[3] specially to the subject of hernia.

And, there, to my chagrin and disappointment, I was able to glean almost nothing. There, from the many eminent authors on medical jurisprudence, on hernia and surgery, I was unable to find a *single case* of purely traumatic hernia, recorded. Certainly, much wás expected from those. of extensive military experience; those who have seen force applied in a thousand forms; particularly in the charge and in retreat, when horses, men and artillery tread and crush the disabled under them. In the explosions of shells and mines; when men are hurled, instantaneously, from their feet, in every direction; when limbs are blown off, internal organs ruptured, the body palsied, the brain and spine violently concussed; and when, from such commotion one or more of the special senses, as the sight, hearing, or speech is forever lost, we would indeed look for the appearance of hernia, as one of the most frequent of all sequelæ, to such violence and shocks. But, Baron Larry in his memoirs is silent on this subject; and, in our own exhaustive "Surgical History of a Civil War"; a war in which, it has been estimated that a million human lives were sacrificed, not a line can be found, on the subject of violence as a cause of hernia.

Yet, even assuming that there positively was none at the time of accident still there was the predisposing, anatomical congenital imperfection or defect of development.

In a case of incarcerated strangulated scrotal hernia, in which it is alleged that the sole provoking cause was direct violence, applied immediately over the fulness, can we, from the presence of the physical characters under our eyes, in operating or at post-mortem examination, determine whether the state of the tissues, is attributable to a traumatism; or to pathological changes? This is of very great importance to ascertain in a civil or a criminal case.

Judging *a priori*, one would naturally suppose that in these times of refinement and accuracy in diagnostic methods, that it would be a very simple matter to differentiate one condition from the other.

If a case were seen immediately after the injury, one might possibly, then and there be able to say whether the external appearances indicated violence.

The presence of discoloration of the integument and bloody extravasate into the loose connective tissues, with patches of ecchymosis would point to traumatism, but, this would be all. After serious inflammation commences in the sac, there is practically nothing, which will in any way, aid us, when discoloration is absent in, separating the pathological from the traumatic. In both, we will, after a very short time, find the skin and cellular membrane thickened, traumified and sensitive; the sac thick, turgescent and distended with a serous,or sero-sanguinolent fluid; the intestine, congested, inflamed or gangrenous. There is then, pathologically, no definite line, by which, a pathological strangulation, can be definitely identified, from one induced by violence, inflicted in any way whatever; short of a penetrating wound. One must, then always exercise great circumspection in many of these cases of injury, in the male or female; in which the groin, the scrotum or the labia are involved, if he would avoid mistakes in treatment, unnecessarily alarm the patient or magnify the importance of the injury. Three years ago I was called to see a young married woman; who while standing on a chair, hanging pictures, slipped and fell, her perineum coming astride the back of a chair. When I reached the house, I found two physicians in attendance. She had been anæsthetized; and taxis had been persistently employed, to reduce a large hernioid mass, in the right labium; but, they utterly failed; when, I was sent for. In examining the case, I found that what they were trying to reduce was a large hæmatoma. Now, in the male scrotum, this mistake is never likely to occur: because of effusion of blood into the tunica-vaginalis or the fascia-spermatica, extending up, to the external inguinal ring. An acute orchitis, complicated by an epididymitis and free cellulitis, with an œdematous, condition of the tissues, might, without a careful examination, be mistaken for hernia, after injury. In every hernial case, coming under our observation, in which violence is alleged, the most thorough and complete examination, is always imperative. In the course of examination, if we are in doubt, the most skilful and experienced surgeon, obtainable, should be sought for, to aid in assuring accuracy of diagnosis. The claim for action rests on the presence of *hernial injury*. But, in a given case, there may be no hernial injury, if there be no hernia. If it can be proved that what was mistaken for a hernia was an old tumor, an enlarged lymphatic gland, new growth, or scrotal complication, the case falls to the ground.

If the pathological condition immediately resulting from injury, partakes of a mixed character, then, unless a full history of the patient's antecedents is obtainable and if we are not permitted to watch the case, over a considerable period of time, an absolute diagnosis will be impossible; a correct knowledge of the precise share, which the chronic pathological condition, or the recent traumatic influences played in the causation, being impossible to estimate.

The Diagnosis of Hernia, Inguinal, Femoral or Umbilical, at Varying Intervals after Injury, which are said to be of a Traumatic Origin.—So far, it must be conceded, that the infliction of physical force, *in itself*, can very seldom cause an abdominal hernia, without at the same time, inducing mortal changes.

While this is indisputable and non-questioned, it must likewise, be clearly understood, that when a tendency to hernia exists; when the formation of one has begun, or one is on its way, through the crural or inguinal canal, force suddenly applied, in various ways, over the abdominal walls or the portals of exit, may, only hasten its full development; yet, it is immature and might never, without such violence, have made its appearance outside the external ring; nor made the wearing of a truss a necessity. Nor, can we doubt, that in those atrophic, diminutive protrusions, lying along the floor of the crural-canal, or just emerging through the external ring, the abdomen, striking with great force, or being struck, concussed or suddenly jammed and its contents compressed,there is a tendency to escape in the direction of the least resistance; when these small painless hernia, may quickly increase in volume and practically invalid the injured, in varying degrees; thereby greatly diminishing his physical usefulness throughout life.

When such cases are brought to our notice great vigilance and circumspection are demanded of us. A moderate swelling in the groin may be made the pretext for an action, particularly when the patient happens to have been on a train, which collided or run off the track; or was one of a few, who escaped in some terrible disaster, attended with considerable loss of life, occasioned, through preventable causes. One of the first questions, which we should ask ourselves, in this class of cases, when the patient is presented to us, is, *has this man a hernia, at all ?*

At first sight, this question might seem a ridiculous one,for it might be asked,is it possible that we are not always able, to diagnosticate with positive certainty, a hernia, from glandular enlargement or neoplastic formation? In the present state of our knowledge, this interrogative, must be answered, in the negative.

For there are cases of this description, wherein hernia is suspected; but it cannot be diagnosticated. This fact cannot be too strongly emphasized; as a knowledge and recollection of it, might often prevent suit for mal-praxis, resulting possibly in heavy losses to the physician.

Within a year, a gentleman, a physician himself, came under my observation, who had been examined by the most skilful surgeons in Brooklyn and New York; some alleging that he had a hernia; others that he had not, while there were a few, who candidly admitted, that they didn't know, what the character of the fullness was. No! I am convinced, that there are few surgeons, of much experience, who do not now and then, meet cases in which, certainty of diagnosis, in inguinal or scrotal swellings is impossible.

Again, admitting that there is hernia, is it *sui generis*, pure and simple a visceral protrusion? This cannot be answered affirmatively either, in every instance.

Such a case came under my care two years ago, in my hospital service. A patient entered, giving a history of injury; from strain as he thought. He was in considerable pain and the house-surgeon thinking strangulation present, proceeded to relieve him by an operation; but when he came on the *fascia propria*, he was rather confounded with what came up into the incision. He closed the gap temporarily, in the tissues. His intervention, probably, by the loss of blood, gave the patient great relief. The next day, I re-opened the wound and came down on a large sarcomatous mass, which had developed in the lymphatics of the extruded omentum.

But, we will meet with well marked, easily defined reducible and irreducible hernia, traumatism, being alleged as the sole causation.

Now are those physical changes of such a character, always present, as will aid us in determining just what rôle physical force played, as an etiological factor? There are, and, there are not. Should we see our patient, within twenty-four hours after injury; then there should be such constitutional and local indications present, as should assure us with considerable certainty, of the nature and extent of the injury borne. On the contrary, if we do not see the case for weeks or months after the violence was sustained, we are powerless to say just what part it exercised, if any. But, by oral examination and a vigorous examination into the condition of the inguinal parieties, the apertures, the spermatic cord, testes and scrotum, we can glean information, which will go a great way, in confirming our diagnosis and revealing the true character of the case.

The following is an instance to the point. Last May, 1891, a well known lawyer in this city, sent a client to me, who told me that while driving a pair of horses, on a street-car, he was run into, by a very heavy express-wagon, the pole of the wagon, hitting him on the abdomen, in the groin and throwing him off the front platform of the car. After the collision he was brought to a hospital and remained over night. On inquiry, I learned, that he did not call the attention of the house-staff to the hernia which he then had, nor did he discontinue his usual work. When he came to me, he had a small incarcerated inguinal hernia on the right side, which he said was caused by the injury. The accident had occurred three months before I saw him.

Now, in comparing the size of the testis, the right was found much smaller then its fellow, on the other side. The spermatic veins were varicose on the same side, and all the elements of the cords were much hypertrophied and of a firm in-elastic feel. I sent my conclusions to his lawyer. There was no suit.

The condition of the testes and the spermatic cord furnish us, with almost incontestable evidence as to the age of the hernia. This is all the more evident, if the patient have worn a truss over a considerable period of time. The pressure of the bulb will have caused a localized thickening and induration of the skin, over the area of it, which corresponds with the internal ring; which is quite apparent, when we contrast it, with the sound side. In connection with this, too, we may look for changes affecting the circulation and nutrition in the cord and testes. The testis owing to trophic changes in the cremasteric muscle, will hang lower than the opposite. The gland will be found changed in texture and often of a diminutive size. It has a soft doughy feel and the epididymis is often so shrunken as to be scarcely made out. In a hernia, the full development of which has been accelerated by an injury, we should, if called, any time, within a week after this has been sustained, find a series of symptoms accompanied by definite pathological changes, of a clear and unmistakable character. There should be evidences of recent tumefaction over the side of the scrotum involved, a thickening of the sac and temporary occlusion of the inguinal canal by a plastic exudate. It will be well to note the presence or absence of peritoneal tenderness in the direction of the iliac fossa, elevation of temperature, acceleration of the pulse, diminished appetite and other symptoms indicative of re-action after shock and local disorganization. If these phenomena are present, we must assume that violence has been sustained. If they are all absent we should then, pronounce our patient's condition, as not having been caused by concussion force; we besides, should aid in unmasking the real character of the impostor and teach him a lesson, that the members of the medical profession are not yet, so degraded, that for any pecuniary consideration, however large will they permit themselves to assist others, in an unjust extortion of money. Nevertheless, that we may commit no injustice, we should always hesitate, and never, finally decide, until a most scientific and critical examination has been made, in every case.

I do not know from *personal* experience, that the herniæ of women are very liable to aggravation from traumatic influence; although it would seem, that such must be rarely the case. The etiological groundwork of female hernia, is totally unlike that in the male sex. They have, practically, no enclosed outlets, from the abdominal cavity. Their femoral herniæ must always be attributable to mal-development; the appearance of the descending viscera being nothing more than an incident. They are certainly not dependent on compressive force; for we never see them occur as a cause of violent or protracted labor, except, perhaps, in the umbilical. Indeed, some of the most intractable of them, being in unmarried, or sterile women. The expulsive act of parturition is attended with very considerable abdominal compression. Not infrequently, when the impatient accoucheur has given up, in despair with forceps traction; the uterine and accessory abdominal muscles, after a short rest, gather fresh force and land the child safely into the world. We can conceive of nothing greater, short of mortal force; yet we, have no hernia, resulting. The same may be said, of female, inguinal hernia. A traumatism cannot cause a sudden development of it. But this is not the case, with the umbilical variety. This hernia without question, often is largely dependent on pregnancy and delivery. The same predisposing element, however, existing, as in other varieties of hernia, but here alone, do we find one, which seems to have an immediate relation, with a physiological condition. Precisely how the parturient state favors umbilical hernia is by no means clear. It certainly leads to that condition, in some other manner than through pressure of the gravid uterus or the expulsive effort of labor, for it is not, in instances specially wherein the uterus attains to the greatest size, or in cases of tumors or ascites; nor either, after tedious, difficult labors, that an exomphacele most frequently follows. Nevertheless, it is only too evident to every one, that after an umbilical hernia is discovered, any sort of sudden force may lead to its increase in volume and, owing to its exposed position it is very liable to injury. But, we will find on dissection, in the vast majority or these extrusions at, or near the navel, that they have formed solid, resistant beds for themselves, by adhesions and adventitious formation; so that they are effectually walled in, and, in many cases not apt to attain greater volume, only under the most extraordinary circumstances. It is well to remember, that in many old umbilical herniæ, their integumental covering is so thin and brittle, through the effects of long, continued pressure, that a moderate blow immediately over the hernial convexity, might easily cause rupture, hæmorrhage, or peritoneal inflammation.

In conclusion, it may be stated with emphasis and certainty, that the direct application of concussive force, is never a primary cause of hernia. That its effects are always secondary and consecutive. That, when a hernia is already present, violence, which might, in the sound, whole individual be borne with impunity, may, if accidentally applied over viscera, which have escaped from the abdominal cavity, cause very painful or mortal consequences. Hence, the herniated, is not a whole, perfect being, so that a comparatively trivial force, which in the normally developed would make no impression, might with him, be followed by serious results.

With those cases, in which violence *per se* is alleged as the cause of the hernia, the condition of the testis, in the male, the spermatic cord and inguinal region, together with a rigid inquiry into the patient's personal and antecedent history, will tend, to throw much light on his condition.

There is no evidence, that ordinary, bodily traumatisms aggravate the herniated condition; except, in those cases, in which, injury is applied immediately over the herniated area.

A more general knowledge of the above facts, by the general mass of the profession, should, while in no way interfering with the fullest measure of justice being meted out to the injured or crippled; nevertheless, greatly restrain those who have a hernia, from making it the sole ground, for demanding extortionate sums, or instituting criminal proceedings.

Discussion.

Dr. I. N. Quimby, of New Jersey, agreed in the main with Dr. Manley, but claimed that there should be taken into account the individual's constitution, and that in cases of doubt in criminal violence the doubt should be solved against the criminal.

Dr. J. G. Kiernan, of Chicago, took issue with Dr. Quimby. The physician had nothing to do with the consequence. His duty was to state the facts found.

Dr. H. N. Moyer, of Chicago, cited a case of ventral hernia in which suit was to be brought for damages. He asked for diagnostic evidence in such cases, and as to the value of traumatism as a predisposing factor.

Dr. Manley, in closing, said that in the case of ventral herniæ predisposing factors existed.

"CEREBRAL ANATOMY."

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY WILLIAM FULLER, M.D.,

OF GRAND RAPIDS, MICH.

Mr. Chairman and Gentlemen:—I have first to thank you for the permission to bring these specimens of anatomy before the Section, inasmuch as they are presented without previous notice, and is therefore a trespass upon your kindness.

I will next ask your indulgence, since I came here wholly unprepared to make any remarks upon them, for the reason that they are casts which are uncorrected by careful dissections which I hope to make in the near future as my time will permit. You will please to accept them as an illustration of what may be accomplished in this line of our work, which I think you will agree with me is important to the progress of our science, since until an exact anatomy of the central nervous system is acquired by the general practitioner so that he is able to make an intelligent post-mortem examination, and describe correctly the location and extent of lesions, our progress must necessarily be slow.

The clinical history of very important cases is neglected, and at present post-mortem examinations are negligently performed on account of the want of anatomical knowledge, in consequence of which we are sadly deficient of data upon which to formulate a rational theory of disease. Medical works on this subject, so far as my experience goes, are unsatisfactory and of little service. Theories are concocted and lines drawn on paper to illustrate the various centers and tracts, which being different in different books are utterly confusing, and even though these lines may be correct representations, it is so difficult to understand the meaning of the author, that the reader commonly gives it up in disgust, blaming his own incapacity, and holding the author in high regard as a man of exalted intellect. His cases are dispatched to the specialist, sent to a sanitarium, or allowed to perish unobserved at his door, and science has lost its opportunity. By means of these casts, which can be made to represent any part of the nervous system, the study becomes at once easy, more easy than from the fresh brain, because they can be turned over, handled, and the relations of parts considered by the student, and can be referred to while reading. I have been asked where I obtained so much material. I will tell you; I seldom have trouble in obtaining permission to open the head, because I promise, and am careful never to leave any deformity of the corpse, or get a drop of blood on the carpet when performing a post-mortem examination. Many opportunities for making post-mortem examination are lost through want of attention on our part to neatness and cleanliness, and to carelessness about producing deformity of the head. Much information is lost in post-mortems by a want of orderly method in the procedure, and more opportunities are lost through the exercise of levity and an air of heartlessness often assumed by the operator and those present. In accordance with the feelings of friends, and assimilated to the environments of the death chamber, gravity and the expression of that earnestness which is appropriate to the countenance of an inquirer is in my opinion in better taste. I speak of this because I think that we should be careful to cultivate the sources of our knowledge by removing all obstructions in the way of opportunity. Students should be well instructed in the methods of making post-mortems, and be examined in this branch of the art as in any other.

The method in which I study the central nervous system, is to commence with the spinal cord, and to notice as far as I am able, the analogies as I pass upward into the brain, which is to be considered as a continuation of the cord inverted, and the fibrous and vascular matter rearranged and adapted to the alteration.

EVIDENCE OF THE SOMATIC ORIGIN OF INEBRIETY.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third annual meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

BY EUGENE S. TALBOT, M.D.,

OF CHICAGO, ILL.

Dr. Langdon Down first called the attention of the profession to the fact that contracted arches and high vaults were common among idiots. Later on Dr. W. W. Ireland contributed largely toward our knowledge of and interest in these deformities. Both of these gentlemen have charge of large English institutions for the feeble-minded; both of them, but more especially Dr. Down, believed that these deformities were pathognomonic of idiocy. Dr. Ballard contended that inasmuch as these deformities were very common among idiots and, as is frequently observed, idiots suck their thumbs, therefore the high vaults and contracted arches were caused by thumb sucking. Later on we shall see that these signs are no more proof of idiocy *per se* than that Hutchinson's teeth are characteristic of inherited syphilis. Congenital syphilis is a constitutional disease interfering with the development and growth of the body, hence the arrest of development of the crowns of the teeth. Now, any of the constitutional diseases, such as measles, scarlet fever, typhoid fever, etc., which also interfere with nutrition, will produce the same deformities of the teeth. After Down, Ireland and Ballard had made known the results of their researches on this subject, Drs. Kingsley, Stellwagon and White, of this country, made extensive investigations in our own institutions of idiocy, and reported that contracted arches and high vaults were, in their opinion, no more common among idiots than among their private patients. I had frequently observed in my own practice quite marked cases of deformities of the jaws and irregularities of the teeth, hence you will observe my analogy to the Hutchinson teeth. That these deformities of the jaws and irregularities of the teeth were found to be nearly, if not quite, as frequent among apparently healthy individuals as among idiots, led me about twelve years ago to take up this particular line of study, with a view of ascertaining, if possible, the cause of these peculiar deformities.

I will not weary you with a recital of the different theories advanced as causes of these deformities, but as briefly as possible will give you the results of my own investigations. You are all aware that the main feature in idiocy is arrest of development of brain tissue; that the growth of the brain is greater between birth and the seventh year, than during any other period in life. After this period the substance of the brain and the different tissues of the body grow rapidly. If the brain be a healthy one, we would naturally expect to find all the tissues of the body developing in a normal, healthy manner. On the other hand, if the brain be diseased or arrested in its development, we would expect to find the tissues of the body arrested in their development. Reasoning from this standpoint, we observe that the different structures which go to make up the body of the idiot are very markedly deformed, and excessive development and arrest of development of tissue are frequently noticed. No other tissues of the body receive so marked an impression as the osseous system. Hence we observe excessive and arrested development of the jaws very frequently.

We noticed that the brain adds but little to its size after the seventh year; irregularities of the jaws and teeth are rarely if ever seen before that period. In other words, deformities are never observed with the first set of teeth. Now it is a singular fact that the first permanent molar makes its appearance at the sixth year. The superior maxilla and the bones of the cranium cease to develop in these cases at that period.

The second set of teeth requires a jaw one-third larger than does the first set, hence in those cases where the superior maxilla and bones of the cranium cease to develop at an early age, there is not sufficient room to accommodate them.

Contracted jaws and irregularities of the teeth always take place between the seventh and twelfth year, and if from any cause arrest of development due to defective brain should result, contracted jaws and irregularities of the teeth would take place at that period. The high vault is modern architecture; it is never seen in ancient skulls, and is more common in this country than in any other. It is always or nearly always noticed in defective individuals, neurotics, etc. Just how it is developed I am not prepared to state. The shape and character of the deformity depends entirely upon the order of the eruption of the teeth. Thus if a cuspid tooth is the last to erupt, the anterior part of the jaw becomes contracted, the incisors are thrown forward and the V-shaped arch is produced. If, on the other hand, the cuspid erupts before the bicuspid, the saddle-shaped arch will be formed. The cause of the deformity is a local one, depending upon a small jaw. There is, however, another cause for the small jaw, that must not be lost sight of, and which is not constitutional but local in its makeup, viz.: If the temporary molar decays early, or is extracted before the proper time, the first permanent molar will advance forward and fill the space made vacant by the removal of the first temporary molar. This condition must be taken into consideration in making up our diagnosis. I only give the cause in a general way for want of time, but each variety is explained in my work upon "Irregularities of the Teeth." Having thus found the cause, the question naturally arises: "Shall we not find as large a percentage of defective among inebriates as other neurotics?" I have therefore examined the mouths of all of these classes. I will now give you the results of my investigations, taking them in the order in which they were made.

TABLE OF DEFORMITIES OF THE JAWS OF THE DEGENERATES.

	No.	Normal.	Large Jaw.	High Vault.	V-Shaped Arch.	Partial V-Shaped Arch.	Semi V-Shaped Arch.	Saddle Arch.	Partial Saddle Arch.	Semi-Saddle Arch.
Idiots	1,977	55.3	7.6	16.	6.5	11.9	. . . .	10.4	. . . .	. . . .
Deaf and Dumb	1,935	45.3	15.7	21.7	8.7	9.9	. . . .	10.4	. . . .	. . . .
Blind	207	50.7	7.7	18.3	3.3	4.3	. . . .	5.3	. . . .	. . . .
Insane	700	62.0	18.	44.	26.	47.00	. . . .	12.	. . . .	. . . .
Criminal	477	36.06	15.72	14.67	2.70	16.56	3.9	12.36	19.28	5.03
*Inebriates	514	25.04	6.4	59.5	1.5	24.4	0.3	9.3	13.2	7.7
Normal	1,000	78.	1.9	5.6	1.1	6.1		3.3	. . . .	. . . .

* The examination of inebriates was made in the Keeley Institute, Dwight, Ill.; the Inebriates Home, Ft. Hamilton, N. Y.; Washingtonian Home, Chicago; Washingtonian Home, Boston; and Dr. Crothers' Institute, Hartford, Conn

It will be observed, that there is a larger percentage of deformities among the inebriates than among any other defective class.

These deformities, however, are not so *pronounced* as those found among the idiots and criminal classes. The large percentage of deformities and high vaults indicate a strong neurotic tendency early in life, even before the seventh year. Finally, if the child from the seventh to the twelfth year has arrested development of the superior maxilla, and possesses constitutional irregularities of the teeth and a high vault, we can almost invariably say that the individual will become, not always an idiot, but a genius in some one direction or an idiot, a deaf, dumb, blind, insane, criminal, an extreme egotist, excessive tobacco user, or an inebriate—all of these conditions coming under the head of degenerates, or neurotics. In making a diagnosis of any one of these classes of individuals mentioned, we should always take into account these three conditions of deformities of the jaws, viz.: arrest of development of the superior maxilla, constitutional irregularities of the teeth and high vaults.

Discussion.

Dr. J. G. Kiernan, Chicago, Ill.:—In a small proportion of inebriates the essential factor is a condition of degeneracy pointed out by Benjamin Rush several decades ago. It was undoubtedly true that a large number of the neuroses and psychoses occurring in these degenerate individuals had a tendency to assume a periodical type. The nerves themselves had periodicity of function. A distinction should be made between three classes. First, there is a vice class among inebriates; second, there is an inebriate class in whom the condition is the result of constitutional defect, but it does not assume a periodical type; third, there are many cases of this periodical type of degeneracy which are a manifestation of the periodical psychoses.

With regard to Dr. Dewey's paper, the fact was noticeable that the majority of cases had associated with them other factors in addition to the hereditary element and drink habit tending to produce insanity, as the morphine habit. The sudden stoppage of morphine in a neurotic individual might bring about insanity.

Dr. H. N. Moyer, of Chicago, considered Dr. Crothers' paper an exceedingly valuable contribution. It showed that inebriety obeys the law of many other nervous diseases. Most nervous diseases in a certain sense were periodical. A nerve never pains continually in neuralgia, and the pain is never equally severe at all times. There are periods of remission.

The matter of Dr. Talbot's paper should not be lost sight of, the somatic origin of inebriety as demonstrated in idiocy and other allied affections which Dr. Kiernan had classed among the degenerate types.

In regard to Dr. Dewey's paper, he thought the author had dealt too leniently with Dr. Keeley. He believed the only gold in the Keeley treatment came from the pockets of credulous patients. An analysis of the remedy as sent out for home treatment had been made in Philadelphia by an able chemist, and nothing of importance was found in the "shot," as it is called. It contains no chloride of gold and sodium, and no strychnia, simply an organic compound, of no marked physiological activity. The "dope" was a mixture of tincture of cinchona and tincture of gentian. It had been his misfortune to have sent four patients to Dwight, and these four had relapsed. The speaker believed the only effect of the Keeley treatment was purely one of hypnotism, to use a term that was much abused. The hypnotism, however, was not applied as physicians commonly use it in producing hypnotic sleep, such as fixing the attention on a distant point, or other means of sensory perception. The hypnotism and suggestion was bound up with the hypodermic syringe, which was used several times a day, and in the association of large numbers for treatment, and the persistence with which they were told that they were cured.

The paper was further discussed by Drs. McClelland and Green, of Michigan, Dewey, Talbot and Crothers.

THE LAW OF PERIODICITY IN INEBRIETY.

Read before the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY T. D. CROTHERS, M.D.,
OF HARTFORD, CONN.
SUPT. WALNUT LODGE HOSPITAL, EDITOR JOURNAL INEBRIETY, ETC., ETC.

The alternation and periodicity of the functions of the brain and nervous system have not been fully studied. Periods of inactivity as in sleep and wakefulness for a definite time, the rise and fall of temperature, increase in heart pulsation and cardiac pressure, the nutrient and reproductive periods, are all common physiological periodicities. This same mysterious alternation appears in the diseases and degenerations of the brain and nervous system.

The neuralgias, migraines and epilepsies are familiar illustrations. In insanity the folie circulaire is equally noticeable.

This rise and fall of nerve functions, together with halts, alternations and relapses in disease, suggest a field of laws and forces that are largely unknown.

The inebriate who drinks to great excess at distinct intervals and abstains totally during the intervening time, is a type of the neurotic character of these strange cycle degenerations.

Literally, and in appearance these cases represent in one person, a type of exemplary living, and a state of alcoholic frenzy, with mental and moral degeneration—recurring within fixed intervals of time.

At one period the victim is a rigid moralist and strict abstainer and by word and example is often a temperance lecturer of an aggressive type whose views are emphatic and earnest. Later, he is secretly and openly an excessive drinker and a low intriguer—displaying the most opposite traits of character and conduct.

Yet the public accept his theories of inebriety and its remedies, and assume his experience as knowledge not possible to others.

Unlike any other victim of disease, his judgment is held in higher esteem, and his views are considered as authority on this topic.

Some general statistics indicate that over 60 per cent. of all inebriates are of this periodic character.

The length of the free interval varies widely from one week to two or more years, and in some cases recurs at distinct intervals not varying more than a few hours.

In others this free interval is very irregular— apparently depending on unknown conditions of environment. In others it follows certain functional derangements and disturbances of nerve and brain health.

In certain cases it appears as mysteriously as a flash of electricity in a cloudless sky, with no premonition or hint, and each attack comes on in an equally mysterious way.

The clinical history of these cases reveal several distinct classes, with widely varying symptoms and conditions.

One of the most prominent groups I have met are the insane impulsive periodics. The free interval varies widely. The drink craze comes on abruptly when least expected. Thus, at some unexpected moment when his presence and judgment are most essential to success, and when the drink craze may be almost fatal, he will fall.

As an illustration, on the eve of marriage, or some social, political, or literary triumph, or business success, this delirium appears.

He will disappear and conceal his condition, or boldly display his insanity in opposition to all advice or entreaty. Then suddenly realize his condition and make a great effort to recover.

Intense sorrow and grief, coupled with explanations, prevarications and earnest efforts to repair the losses will follow.

Often he will ascribe his recovery to some means or remedy taken at the last moment and defend it with delirious faith and energy.

He is often unable to give any rational idea of the motive or reasoning which preceded the drink craze.

His memory is always vague as to the nature of his acts, and although events may be clear, the higher consciousness is cloudy.

The reason and judgment seem to be suddenly arrested by some morbid impulse which palsies every other consideration.

These paroxysms come without any apparent premonition, and are a surprise to the victim and his friends.

The drink thirst continues up to a certain point and then dies out suddenly.

The character of the acts in this delirium vary from maudlin religiosity to wild aggressiveness—and through all degrees and forms of insane acts.

Men in this state will display delirious zeal for the temperance cause and be very prominent in revival religious and charity meetings during the free interval and continue it during the onset and decline of the paroxysm.

The height of the attack is marked by coma, or extreme delirium, with delusions, hallucinations and hyperæsthesia running into intense egotism, ending in a period of bold hypocracy and self deception. This in turn gives way to the normal, mental and moral status which continues to the next period.

Another class of these periodics will display distinct premonitary symptoms of the drink storm and like the first class will be clearly unconscious of it.

The more common of these symptoms are degrees of unusual excitement or depression, great business energy or apathy,or especially brilliant mentality or the opposite.

Often they exhibit alarm for their future state, fear of poverty or dread of sudden death. Then suddenly the drink delirium appears, and an entire change follows. When this subsides the old delusions are not taken up. Deep depression generally ensues with a partial or total blank of memory or a delusion of some particular pleasing or unpleasing event in the paroxysm. Not unfrequently marked hallucinations and vague delusions continue for a long time.

The drink insanity is sometimes filled with short periods of pretended effort to abstain, or of intrigue and low cunning to defeat the efforts of others to help them. Such men appear at the prayer and temperance meeting, appeal to the benevolent, pass as examples of cure by some strange mental or moral remedies. Egotism seems to be a dominant mental symptom, together with duplicity and prevarication. When the paroxysm dies out all this false character disappears.

A third class after a period of prolonged sobriety will have premonitory periods of delusive reasoning, usually that they have some disease which requires spirits as a remedy. They appear in good health and seem oblivious to any past experience in which the same idea preceded former paroxysms. After a drink of spirits as a medicine, the drink storm comes on. When this is over they do not stop abruptly, but continue in decreasing doses until final subsidence.

Then comes a period of food and health delusions, marked by unusual care of themselves, their surroundings and nutrition. Such cases are not unfrequently checked in the midst of a drink paroxysm, by some powerful mental emotion as an appeal to their fears, forced changes in their surroundings, or abrupt shocks to their ambitions or purposes in life.

Often the paroxysm is marked by some condition which breaks out again when these restraining states are removed. The value of chemical restraint is by covering up the impulse and thus holding it a long time in abeyance, but only as a rule to break out again. This class is prominent for the mental symptoms of paranoics, and are rarely seen occupying positions of trust and responsibility long. They develop general paralysis and melancholia, and often die of suicide.

A fourth class is noted by the exact recurrence of the drink cycles, irrespective of all conditions and surroundings of life. The paroxysm is sudden and impetuous and the mind is filled with delirious conceptions of pleasure from the tastes and effects of alcohol.

This state may be concealed for a time, but grows steadily until full gratification follows. Such cases suddenly assume some burden of reform, with a secret hope to break up their imperative conceptions. The most careful plans for the concealment of the drink storm, are often made which end abruptly with no especial depression or moral regret. The memory of acts committed during the storm is cloudy, and the free interval never varies in time and hence a certain expectation is created in the mind which prepares for it.

Many of these cases are engaged in the work of helping others and exhibit obscure acts which are only explained by the presence of this fated periodicity. These cases never can give any rational reason or explanation of their conduct and as a rule always try to conceal it.

The heredity of these cases is prominent. So far over 90 per cent. of all cases of periodicity have a neurotic heredity.

Insanity, epilepsy, inebriety, hysteria, idiocy, dementia, paranoia, also phthisis, rheumatism and the various organic heart diseases are present in the parents and grandparents, indicating an irresistible neurotic degeneration coming from the ancestors. All these neuroses are interchangeable and may break out in periodic inebriety from special but unknown pre-disposing causes. The recurrence of the drink paroxysm is of itself evidence of a neurotic origin involving the higher controlling centers.

It is a question of great interest to determine how far this neurotic tendency to break out at distinct intervals in morbid impulses for the narcotism of alcohol, is a direct inheritance or whether it be one of the symptoms of obscure disease. Children of inebriate parents often have distinct hereditary predisposition to use alcohol.

Coming from neurotic patients the marked tendency is to arrested growth and development before birth, enfeebled power of adapting themselves to environment for the first few years of life, irregular development and precocious growths in certain cases at puberty.

The degenerations from functional organic diseases which the system is unable to overcome, the morbid tendency to exhaustion of the higher nerve centers and the faulty maturity of both organic and functional activities. Add to these the common errors of environment and nutrition and the hereditary taint or tendency to develop certain distinct nerve diseases is inevitable. It is often developed disease with a neurotic basis or favoring tendency.

The drink craze as at present understood is a symptom of central nerve and cell debility demanding relief from the narcotic action of alcohol.

Why these states of brain anæmia or irritation of function should gather and explode at periodical intervals is not clear. The same states of degeneration both acquired and inherited appear in epilepsy and other neuroses, showing that they are clearly allied family diseases only varying in symptoms.

As in epilepsy, the periodic inebriate suffers from disturbance of the coördinating and inhibitory apparatus of the higher brain centers.

Nerve energy is not liberated along motor tracts, but through mental areas in the impulse for rest from the paralysis of alcohol. The discharging energy is neutralized by chemical restraint. The physical and psychical energies of the brain centers are overcome by continuous narcotism, for the time. Then a period of normal activity follows in which this explosive impulse is dominant.

These paroxysms resemble epilepsy in origin, onset, duration and termination. They differ in being confined to consciousness and mentality with a central object for relief.

After the explosion the mental operations seem normal, and along the levels of comparative health. Opium and other narcotics will bring the same relief at these times, but probably they are followed by more organic disturbance which demands their continuous use.

The increase and diminution of alcohol from brain circulation and the vaso-motor paralysis together with reduced temperature, non-elimination of organic products and slowing up of both functional and organic activities, to the verge of total suspension, followed by a rapid return to apparent normal states, is peculiar to these cases. In all probability the periodic inebriate, in many cases, is largely a masked form of epilepsy, and is the result of special unknown exciting causes and conditions.

The steady drinker will after a time, have alcoholic epilepsy from continual irritation of the cortex; or may become a periodic inebriate—*manifesting* at times a delirious craze for alcohol, and then having a free interval of sobriety. The same causation seems to be prominent in both.

The same profound cerebral anæmia or irritation that breaks up coördination and perverts nerve energy, may develop into a convulsive discharge through the motor tracts, or a convulsive impulse for spirits and relief.

The natural function of the brain, to gather and discharge energy, is impaired and the force essential to the normal working of the organic life explodes at intervals with destructive energy.

These periodicities are more common after twenty when the organic activities of the brain have become matured, and often subside or merge into some serious nerve or brain degeneration before fifty.

In many cases they appear to follow a natural cycle, beginning in a short period of continuous drinking, then a drink paroxysm with long free intervals.

The length of the paroxysm increases up to a certain point—then grows shorter commencing in a single day or night's indulgence—it grows until it covers two or three weeks of time, then becomes less and less until finally a day or a few hours is the utmost limit of toleration.

The system then refuses to retain any more spirits, and an intense loathing and repugnance follows.

The free intervals likewise change, at first extending over months, and often one or two years—they grow gradually shorter—until they reach a minimum of a day. Then increase until the drink craze finally dies out, or death follows.

This rise and decline in length of the drink and free interval period, points to some unknown law of accumulating nerve force and degeneration. The fundamental principle running through these periodicities is the steady uniform march of degeneration, manifest in *explosions of nerve energy* for narcotism and relief.

The force generated in the nerve centers concentrates, and reaches a degree of tension that is only discharged in the acute delirium and coma of alcoholism. Narcotism from opium, cocaine, chloral and similar drugs have the same effect, with greater prostration and nerve lesions, which demand its constant repetition. The narcotism of opium, chloral and other drugs is never followed by repugnance and a free interval of relief and rest.

Hence, the treatment of these drink paroxysms by the substitution of other drugs is always dangerous.

It is a question of grave importance how far such cases are to be considered of sound mind and capacity.

Is it possible for any one to be narcotized for a week or more at different intervals and yet retain normal reason?

Does the brain fully recover from these explosions and the chemical and physiological effects of alcohol, when used to excess, even though followed by a free interval?

The popular opinion, even among physicians is, that such symptoms are often signs of genius and eccentricity, and are rarely to be considered as evidence of disease.

Clinical study brings no support to such views, but on the contrary, points out grave changes of the higher brain centers seen in failure to both reason *and control the higher brain activities.*

While the higher and psychic brain steadily degenerates, the lower motor and automatic brain goes on masking and concealing the evidence of disease.

Along the normal lines of every day's thought and work, the apparent health of the victim may be unquestioned, but vary this and his real condition becomes apparent.

Let the periodic inebriate change his occupation and surroundings and this incapacity and unsoundness will be prominent. Practically the periodicity of the drink craze, together with its intense unreasoning demand for narcotism is an unmistakable sign of disease. *Literally* both this morbid impulse and the effects of the gratification break up the coördination and the inhibition of the higher brain centers, impairing the capacity for healthy brain reasoning, and leaving states of debility and unsoundness. The failure to realize this fact is followed by very serious losses, accidents and tragedies every day.

The periodical inebriate should of all others, receive immediate medical care. There is impending peril and danger in his case far more than in the regular drinker. His case should be studied and the various pre-disposing and exciting causes *removed,* and the real disease discovered, of which the drink craze is only a symptom.

While the periodical inebriate may live many years and attract no attention medically he is always the center of possible grave disorders, epilepsies and paralyses. His conduct is a succession of disappointments, of failure and losses, that are viewed from the moral side. Overweening confidence and boasts of strength and abject failures are constantly repeated. Many of these cases become paranoics and dangerous to society. The very complexity of the causes and symptoms, make them fit subjects for mental delusions and epidemics and enthusiastic supporters of all changes and events involved in mystery.

The mystery of these drink cycles in themselves prepares the mind for credulous, unreasoning superstition and conduct. The number of periodic inebriates, in all conditions of life, is very large and while they do not attract much attention, are unquestionably the most dangerous brain and nerve defectives in the community. They are amenable to treatment and are both curable and preventable. The periodic inebriate, like the epileptic, has been mustered into an organized cycle of degeneration and death and there is no escape except by applied forces of science.

This is the new psychological territory opened for settlers with its boundless wealth of facts and laws pointing to causes and conditions that are preventable, awaiting discovery and application, promising a new era in medical science. As a summary of this brief study:

1. The periodicity of the drink paroxysm is unquestioned evidence pointing to central brain lesion.
2. Heredity, nutrition, mental exhaustion and environment are all very common causes, or pre-disposing factors, of this condition.
3. Allied diseases, of which epilepsy is very common, are associated with this, and similar affections are interchangeable.
4. The drink periodicity follows a uniform line of events ending about the same way in nearly all cases. Its varieties and symptomatology are practically the same in the regularity of origin, development and termination.
5. These cases are the most certain and dangerous of all drink neurotics and are the least understood. The prognosis is uncertain and full of dangerous possibilities and the natural tendency is death.
6. These cases are very susceptable to treatment when the measures are applied scientifically and with full knowledge of the causes. Their inebriety is more positive than that of other inebriates. The drink impulse is often controllable and frequently disappears with treatment. This class requires the most careful medication and study.
7. Medico-legally the most important problems are associated with these drink paroxysms. Each case requires special study and is to be judged from general principles of physiology and psychology.
8. Such cases of necessity have impaired nerve control and cannot be measured by the rules or standards of mental health.
9. All these cases should receive careful study and examination. Tabulated facts of sufficient number and accuracy are needed from which to draw accurate conclusions covering the laws which govern this class of neurotics. Their curability is assured when the causes are known and by the application of means known to science.

"DELUSIONS AS TO LOCALITY" A PROMINENT SYMPTOM IN THE MENTAL DERANGEMENT OF CHRONIC ALCOHOLISM, WITH A TENDENCY TO DEMENTIA.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY L. D. MASON, M.D.,
CONSULTING PHYSICIAN INEBRIATES' HOME, FORT HAMILTON, L. I.

After an attack of acute alcoholic delirium either of the febrile or nonfebrile type not unfrequently instead of a reasonably rapid convalescence the patient passes into a mental condition that becomes more or less chronic—as there may be a history of one or more preceding attacks of delirium tremens, and more especially the nature of the treatment to which the patient has been subjected, for I firmly believe that the administration of large and frequent doses of the various depressing drugs, as chloral hydrate, the bromides or other cerebral sedatives, while they may promptly relieve the more acute and urgent symptoms by producing a more or less profound cerebral anæmia, will also tend to protract the recovery of the patient towards his normal mental condition, if not precipitate him into a complete or partial dementia. But from whatever cause it may arise, we find mental weakness in some degree, the condition of the average inebriate as he comes out from under his attack of acute delirium.

In the partial form of dementia he can dress and feed himself, but he is listless—indifferent, not prone to exercise—under reasonable control, but full of delusions, dependent upon the amnesia which accompanies his demented condition, so that the memory is obscured as to present events, and operates and acts largely in the past, so that persons long since dead are supposed to be living—acts and circumstances of the past become those of to-day. There is a marked similarity between this form of dementia and senile dementia—they have many points in common—in both the memory is weakened or absolutely deficient as to present events, and events intermediate, between the past and the present, so that the mind operates largely in the past. Lives in the past and past events are transferred to to-day, or as it is said, "Lives are lived over again." Now prominent among other delusions, we find in the form of dementia under consideration what we may designate as a "delusion as to locality," by which we mean to imply, that the subject of it imagines that at stated intervals he visits certain places, sees, converses with, and transacts business with certain people—and those persons, places, and forms of business are those to which he was accustomed in the past; and while it is true that the condition that thus calls back the past, and causes the subject of it to be surrounded with, and live as it were, in the past, is the product of a diseased mind, it is equally true that the persons, places and events so recalled, are not the vagaries of a disturbed mental condition, but the persons and places did actually exist, and the circumstances did actually occur, but they are in relation to the patient matters of the past; for weeks, months or years it may be, he has not been brought in contact with any of these persons, places or circumstances.

He has not for several weeks or longer, left his room, or the limits of the institution in which he is confined, and yet he believes that he daily visits his business haunts, sees old friends, and transacts the daily routine of business; by some leading or suggestive questions as, "Have you been in town to-day?" "Whom did you see?" "What business did you transact?" A reply in the affirmative is inevitably the case, and sometimes the patient will give in detail, the particulars of his imaginary visit.

Now it may be inferred that the weakened mind takes readily to a leading or suggestive idea put as a question, and accepts it as a reality. But I do not believe such to be the case, for the patient will adhere to his delusion without much, if any variance, at subsequent periods, all through the period of his demented condition, the delusion fading away gradually, disappearing as his normal mental condition asserts itself. Like many similar delusions in the mental history of the insane, while it is the first to come, it is the last to leave.

This peculiar and prominent delusion of partial alcoholic dementia we designate as a "Delusion as to locality," as probably best expressing the condition involved.

Authorities do not give this peculiar delusion as occurring among the many that affect the insane, if we except the condition known as senile dementia.

Blanford reports a case "In which the insanity was the result of drink," and had terminated in dementia in which the person believed that he drew checks and got his servant to cash them, whereas he did not do anything of the kind, his affairs being entirely in the hands of a trustee; he simply imagined he did that which he was accustomed to do in the past.

I do not feel competent to exclude the whole field of mental derangement, other than alcoholic, and assert that this peculiar delusion is limited to the latter class of cases, and therefore, it would be of interest to secure the experience of the Section on this point.

A typical case, one of several that have come under my observation, was that of a master of a vessel, who was confined in the Inebriates' Home at Fort Hamilton, and under my care and observation for at least three months.

He was about 55 years of age. had been a sea-faring man all his life, he had no history of head injury or syphilis; he had sustained a fracture of the ribs and general contusions in an accident at sea.

He had drank more or less freely for many years. He was brought to the institution by his wife, because of his mental condition. He was able to dress and feed himself, but his mental powers had progressively weakened for some time. He sat in his room in the institution, was listless, non-communicative; except when questioned, spoke but little.

He believed that every day or on stated days, he visited New York City, where his ship was laid up, saw the ship owners, went aboard, attended to the lading of the vessels, and got her ready for sea; in other words, performed the usual duties of the captain of such a vessel when in port. One afternoon he told me he had been on a cruise to New Orleans, and had just returned. This delusion, that he performed the duties pertaining to an officer of ship, daily or occasionally, adhered to him during his residence in the institution. When he left the institution the delusion still continued, and the partial dementia still existed. His wife said he was very much like a child, he could be coaxed, and as a rule, was fairly well controlled. She gave him ale or beer occasionally. He lived for several years after he left the institution, and died in April, 1891, from an acute attack of bronchitis. His wife has since stated that the delusions did not trouble him during the latter years of his life; that there was not any progressive weakening of his senses; no partial paralysis; that his speech remained good, and that he was useful about the house, and quite helpful up to the day of his death. Several years covered the period from the first appearance of his dementia until the date of his death. In other cases the delusion will take form according to the previous occupation, and antecedents of the patient.

The physician will attend to an imaginary practice, the farmer cultivate an imaginary farm, and the merchant transact an imaginary business, etc.

It is of importance to call the attention of the Section to the fact that this "peculiar delusion" is usually elicited or called out by a direct question from the physician, and may escape notice, if an effort is not made to bring it into prominence by proper interrogation. It would be satisfactory also to ascertain to what extent the members of the Section have observed this peculiar delusion, in the various forms of mental derangement, exclusive of senile dementia, and alcoholic dementia.

Also in what proportion of cases of alcoholic dementia they may have observed it. If it is peculiar to the latter form of dementia, it will be of value in the differential diagnosis, between alcoholic and other forms of dementia.

NOTE ON THE RELATION OF THE SYMPATHETIC TO THE CEREBRO-SPINAL NERVOUS SYSTEM.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY HAROLD N. MOYER, M.D.,
ADJUNCT PROFESSOR OF MEDICINE, RUSH MEDICAL COLLEGE, CHICAGO.

Stewart[1] in opening his article on the disorders of the sympathetic nervous system, says: "Although the physiology of the sympathetic has been advanced considerably within recent years, there has not been a commensurate advance in our knowledge of its diseases. In fact, with the exception of a few important disturbances which we know to have a direct causal connection with alterations in the sympathetic, our knowledge of its diseases is very superficial and in many cases purely problematical." He then gives the following list of the chief disorders attributed to changes in the sympathetic, hemicrania, exophthalmic goitre, angina pectoris. Addison's disease, diabetes mellitus, unilateral hyperidrosis, glaucoma, neuro-retinitis, and ophthalmia neuro-paralytica. He does not mention neuralgia, neuritis or any of the common disorders to which nerves are liable, and yet neuralgia of the abdominal sympathetic is a comparatively frequent affection. Indeed, most modern writers have neglected this disease, seeming to regard it as synonymous with colic. It is this habit of applying the general term colic to all painful disorders having their origin in the intestine that has done so much to obscure our conception of the diseases of the abdominal sympathetic. Thus, Ross[2] in speaking of the cœlic plexus, describes neuralgia mesenterica, and as synonyms employs the terms colic, enteralgia, and colica saturnina. That he regards these conditions as practically identical is apparent from the description, where he says that "enteralgia or intestinal colic consists of pains in the abdomen, having their seat of maximum intensity about the umbilical region." He mentions neuralgia of the gastric and hepatic plexuses, but it is only when describing the disorders of the cœlic plexus, that he seems to regard pain in this region as identical with colic. Romberg[3] clearly pointed out the error of applying the term colic to every pain having its origin in the intestinal tube.

[3] Romberg, Diseases of the Nervous System.

In this he was not alone, as Thomas Willis[4] had described essential neuralgia of these parts long before and had clearly distinguished between the colicky pains vulgarly termed the gripes and the disease in question. The former attacks all classes of people indifferently, is caused by incongruous or unusual beverages, diet, taking cold, etc. The latter, however, develops in persons who are predisposed, it has peculiar features, and is probably dependent upon an essential cause differing from the accidental ones named as originating the first group.

The severest case of abdominal neuralgia that ever came under my observation, was that of a young man 26 years of age, single, of good habits, who was employed as a salesman in a feed store, and led a temperate, active life, with plenty out of door exercise. He was apparently in perfect health, his complexion was ruddy, appetite good, and bowels regular. For the past seven years he had suffered from excruciating pains in the abdomen; the attacks would come on at intervals of from one to three weeks, and would last from 24 to 72 hours. The pain would begin as a dull ache, having its point of maximum intensity, about the umbilicus, it would gradually increase in severity until it was quite unendurable. In the attacks when I saw the patient, the abdomen was usually retracted, the pulse was small, and the pupils moderately dilated. The face was often covered with perspiration. The pain would increase for some time, reaching the maximum at the end of twenty-four or thirty-six hours, it would then gradually subside until it had entirely disappeared, and the patient was again in apparently perfect health. While the patient has suffered for seven years, it is only during the last three, that the disease has acquired its present severity. At no time during the attacks was there any tenderness upon pressure, nor did pressure afford any relief to the pain. There was no rise of temperature during the attacks, though it was frequently taken. While the pain always began about the umbilicus, after some hours it would radiate to all parts of the abdomen, and would apparently pass a short distance above the margin of the ribs; it extended into the loins when the attack was at its worst.

During the time this man was under treatment, which extended over some months, every possible source of reflex irritation was looked for. The stools, urine, bladder and rectum were carefully and repeatedly examined, but were invariably found to be normal. During the paroxysms of pain the stools were always regular, and the fæces well formed. An important fact in this patient's history was that at no time did he present any of the usual symptoms of neurasthenia. He had used morphine for some years to control the pain but had not become an habitual user of the drug. He was rigorously treated in a variety of ways. The constant current was used with at first quite marked effects, but it soon ceased to exercise any control over the disorder. Various antineuralgics were employed, but like morphine, they seemed to exercise only a temporary influence. The patient realizing that I could do little for him finally drifted away; the last I heard from him was that he was having his attacks with their old time regularity, and he had settled down to the belief that with him they were a fixed and irremediable condition.

My reasons for regarding the above case as one of pure neuralgia of the abdominal sympathetic is that it closely resembles neuralgias of the cerebro-spinal nerves in its paroxysmal character, the freedom from all associated structural changes in the organs supplied by these nerves, the unaltered secretions and absence of all signs of inflammation. Of course the absence of tender points and the tendency of the pain to radiate to different nerves and plexuses until apparently all within the abdomen were involved, could be affirmed *a priori* when we consider that this portion of the nervous system is made up largely of non-medullated nerve fibres and closely associated ganglia.

Another case was one in which the cardiac and pulmonary plexuses were involved. A man 38 years of age was sent to me from an adjoining State, with the following history. Three years before he began to experience pains in the chest radiating from the sternum in all directions, but especially over the precordia. There was a good family history and an account of previous good health. The onset of the pains were gradual, but they increased in severity until now they are at times very severe. He says that he is never free from some uneasy feelings in the chest. The man is in excellent health, has never a cough or any severe illness. His digestion and appetite are good and he sleeps well when not disturbed by the pain. He admits having used tobacco excessively for many years, but for the last twelve months has stopped it entirely. An examination of the heart shows arythmia but no enlargement or murmur.

I have detailed the above histories for the purpose of showing that so far as one common form of nerve disturbance is concerned the sympathetic nerves do not behave differently from those of the cerebro-spinal system.

Most writers seem to regard the sympathetic as having peculiar and distinguishing functions apart from those possessed by other portions of the nervous system. Doubtless much of the obscure theorizing regarding the pathology of the sympathetic has its origin in the vague and fanciful notions held for so many years by the older physiologists.

Bucke, of London, Canada, claimed that the moral nature of man resided in this part of the nervous system, and in one case of insanity associated with marked moral perversion he searched these ganglia closely for anatomical changes.

Even yet it is the custom of our standard works to look upon the nervous system as composed of two divisions, the cerebro-spinal and sympathetic, but Dr. Gaskell pointed out the erroneous nature of such an assumption, and showed that the so-called sympathetic system was but an expansion of the cerebro-spinal nerves. The chief reason relied upon by the older anatomists for making this distinction was morphological; the presence of numerous ganglia and the fact that the greater bulk of the fibres were non-medullated, or the so-called grey fibres. Later research has abundantly shown that these structural differences are more quantitative than qualitative. Non-medullated fibres are found in the spinal nerves in considerable numbers; these nerves are also associated with nerve cells irregularly aggregated but in small numbers, usually at the point where they break up to form plexuses before passing to final distribution. Bearing in mind, therefore, that these structural differences are of degree and not of kind, we are better prepared to regard the nervous system as an entity and we shall reach a much better understanding of its different parts. What structural differences there are is due to the fact that it is through the cerebro-spinal nerves that the principal sensations from the skin and voluntary impulses to the muscles pass. Of necessity these fibres must be insulated; they must have a medullary sheath. If such were not the case there would be an interference with sensations and we would not be able to locate the point of impingement upon the surface. Again, the voluntary movement of a single muscle presupposes that the impulse which gives it origin shall start from the cortical centre and travel upon a medullated, *i.e.*, insulated fibre to its termination in the particular muscle. The older and indeed current writers on this subject said it was the peculiar function of the cerebro-spinal nerves to preside over the voluntary functions, in contra-distinction to those of the sympathetic whose function it was to govern the involuntary or vegetative functions. If we could strip the cerebro-spinal nerves of every sensory and motor medullated nerve fibre we should find almost the exact counterpart of the sympathetic system. A careful examination of the anatomical structure of the sympathetic shows that these conclusions are correct, as no fibres are found to have their origin in the ganglia but all are derived from the cord. For the most part they have their origin in the inner side of the posterior horns and they are at first medullated, but as soon as they reach the ganglia they loose their insulating sheath, that is, the greater part of them do, and pass on to their distribution. A relatively small number of medullated fibres persist in the sympathetic just as a relatively small number of non-medullated fibres are found in the cerebro-spinal nerves. The error of the older writers was in regarding the cerebro-spinal nerves as being distinctively motor and sensory, overlooking the fact that they possessed to a marked degree the vegetative or trophic functions. We venture the prediction that only for this unfortunate misconception of the functions of these two great divisions of the nervous system we would have a much clearer knowledge of many pathological processes than we now possess.

---

[4] Opera Omnia. (Ibid)

We may divide the development of this subject into three stages. In the first physiologists divided the nervous system into two parts, the voluntary and the vegetative. This relegated the sympathetic, to a position not much more important than held by ordinary connective tissue. The second stage was ushered in with the discovery of the vaso-motor nerves and the fact that most of the cerebral ganglia were connected by filaments with the sympathetic and that many of these exercised a direct influence on the calibre of the blood vessels to which they were distributed. With this epoch came much of the bizarre pathology that linked many strange disorders, such for example, as hemi-facial atrophy to changes in the sympathetic. It was such an easy matter to sever the cervical sympathetic and note the dilated capillaries, therefore the atrophy of the same region must be due to changes in the circulation. As a matter of fact this disorder is much better explained by referring it to trophic disturbances in the fifth nerve. These and other erroneous conceptions were accentuated by the fact the sympathetic is concerned in regulating the blood supply of the great organs; their relative importance in this respect has obscured the fact that the spinal nerves have the same function. In fact there is not a single difference in the function of these two systems, so-called, that is not readily explainable by these structural peculiarities and by differences in the office of the organs to which they are distributed. There is not a single basic function of nervous tissue which they do not possess in common.

The third stage will, we hope, be one in which the nervous structures are described, not as being divided into two systems, but one in which the sympathetic nerves are regarded as branches of the cerebro-spinal, subject to the same laws of functional activity and liable to same accidents and diseases. With this more correct understanding of its relations, we look for increased interest in its structure and functions and a better clinical grasp of its disorders.

SURGICAL INTERFERENCE IN CEREBRAL DISEASES OF CHILDHOOD.

Read by Title in the Sectio [illegible] urisprudence, at the Forty-third Annual [illegible] lical Association, hel [illegible]

BY FRANK PARSONS NORBURY, M.D.,

OF JACKSONVILLE, ILL.

It is the object of this paper to consider the advances made in the pathology and surgical treatment of the cerebral diseases of childhood. It is not deemed necessary to recite the history of this progress, nor to enter largely into the discussion of the theories upon which much of the modern surgical interference is founded. There can be no question as to the advisability of interference by surgical means when the known pathological conditions are such as to warrant the hope for improvement. But gross theoretical speculations as to the pathology, such as have been advanced relative to microcephalus, are not scientific and are not sufficient to admit of operative procedure. Starr has rightly said, that the solution of the problem of operative treatment, in cerebral diseases of childhood, must be based upon two conditions: First, the pathology of the cases; and secondly, upon the results of experience when such operations have been done.

Microcephalus.—The pathology of affections peculiar to childhood has not received the study it deserves by operators, and others advocating surgical interference. Especially does this apply to microcephalus, the relief of which, by linear craniotomy, has been so strenuously advocated, by surgeons on both sides of the Atlantic. While Lannelongue has modified the original theory, that advocated by Virchow, viz.: that microcephalus was due to premature synostosis, by saying that the condition is due to maldevelopment of the brain, and the changes in the cranium are secondary, yet he persists in doing the operation, hoping thereby to stimulate brain growth. Microcephalus is a true pathological condition having intra-uterine arrestment of brain development as a cause. Whether disease of the fœtus, or nutritive changes from other causes, are primary in producing this result, we are unable to say. There is deficiency of structure, as well as malformation, of the brain, and synostosis is not a factor in producing this narrowing of the brain in all its diameters.

Concomitant as it is in almost all cases, yet microcephalus may exist without it. Down, of London, reports cases of microcephalus where the sutures were not closed, even the medio-frontal suture, which is ossified during the first year of life, was open. He says: In my own observation of the crania of two hundred idiots, the arrest of development was not the result of premature ossification of the sutures. He further says, in speaking of one particular case: "I am desirous of placing on record this extreme degree of microcephalus, without any synostosis, as a striking example in which other than mere mechanical causes must be looked for as productive of this and analogous cases."

Shuttleworth, after reporting a similar case, says: "I am inclined to think that the premature synostosis is, as a rule, the consequence rather than the cause of imperfect brain development, and that the arrest of growth is about the sixth month of gestation."

Fletcher Beach supports this view, as also does Ireland, who says in many microcephalic heads the fontanelles are open and the sutures not united.

To Wilmarth we are indebted for much of the advancement made in the pathology of idiocy; he in his extensive autopsies has found but one case where any brain compression existed, while in most cases the convolutions were full and rounded. In a private letter to me he says, "There is very little evidence that microcephalic brains result from compression of the skull, but on the contrary there seems to be in nearly all cases an extra amount of subarachnoid fluid, with no flattening of the convolutions, or other indications of intra-cranial pressure, as if the skull had grown slightly beyond the brain. If the conditions arose from cranial pressure, all parts of the brain should suffer alike, as the brain may be regarded as fluid, so far as transmission of pressure is concerned. I agree with you that the defective growth is more often due to nutritive faults, which we do not at present understand."

My own studies based upon anatomy, embryology, pathology and clinical observation, have convinced me that in microcephalus we have to deal with conditions not amenable by surgical means. Anatomically speaking we recognize that intellectual development depends, as Meynert says, on the uniform structure of all parts of the brain. In microcephalus, we find absence of cortical structure, necessary to normal mental development, and that the degree of idiocy is not dependent so much upon the degree of microcephalus, as upon the amount of structural deficiency. The smallness of the skull is no criterion of intelligence, in these defectives. The structural deficiency is shown in effacement and interruption of convolutions; the simple and defective arrangement of fissures; the absence of the central portions of the brain, and atrophy of the lobes, especially the frontal and occipital. Microscopical examination shows diminution in number and absence of ganglionic cells in certain layers, and deficiency of nerve fibres.

Embryology teaches us that the brain is developed early, but that it is not until near the fourth month, the most important portions are shown; then it is the frontal, occipital, parietal and temporal lobes can be distinguished, and the primary fissures are pronounced. The secondary fissures appear between the fifth and sixth months; the occipital lobe should cover the cerebellum at the sixth month, according to Beaunis and Bouchard. In the seventh month nearly all of the main foldings of the hemisphere come into view, the frontal lobe elongates, the Sylvian fissure narrows to a cleft. In view of these established facts we conclude from observations of the brains of microcephalics, which in so many cases show evidences of arrestment before the evolutionary processes above stated are completed, that arrest of development occurs at or near the sixth month of gestation. An embryological study of the process of ossification does not sustain the theory that synostosis is the cause of microcephalus.

Embryology shows that the vault of the skull is formed in membrane and the base in cartilage, and pathology often makes the distinction more manifest (McClellan), which it does in microcephalus. The ossification in the base is well advanced at birth, and the vertex may or may not be completely ossified, according to the precocity of the osseous system, "existing without any correlation between the growth of the brain and skull." Wilmarth says, "I am convinced that in the majority of cases the skull does not grow simply because the brain does not." My own observation is that skull growth is dependent upon brain growth only to the extent of localized nutritive interference on the part of the brain reflected upon the skull, as in flattening following sclerosis. General lack of skull growth depends on general nutritive interference, which, while it may affect both brain and skull, does not necessarily do so, as evidenced in synostosis, and also in open fontanelles in microcephalus. We conclude, that synostosis is the result of arrested brain development, without interference with the process of ossification. The results of experience when the operation of linear craniotomy has been performed do not sustain the claims made for it by Lannelongue and his followers. Statistics of operations performed, which I have been able to gather, show such meagre results and such great mortality, both in this country and Europe, that it seems to me folly to continue to advocate linear craniotomy. Those who have survived the operation have in some instances improved, but there is no evidence to show that such improvement would not have taken place by as persistent efforts at training before the operation as after. Time, that important element which should be taken into consideration in estimating the results of linear craniotomy, has been lost sight of, in the haste to report the operation. The efforts put forth to elicit improvement, and the attention given the child by the parents and all interested in the case, would even in the most profound cases of feeble-mindedness, have some noticeable mental improvement as a result. Those who are familiar with the training of feeble-minded children, have found no encouragement in the operation, and one after another have assured me they have little "sympathy with that kind of surgery."

Persistent physiological education, such as is to be had in thoroughly equipped institutions, can accomplish more without linear craniotomy as an adjuvant.

Epilepsy.—The treatment of epilepsy has received much attention during the past year, both by surgeons and neurologists, and while our knowledge of the pathology of this disease is still very obscure, we have advanced appreciably, as to the value of surgical interference.

All who are familiar with epilepsy are aware of the persistency of the attacks in spite of all treatment, and how comparatively few cases are cured, clinical reports to the contrary notwithstanding. In a paper read before the Illinois State Medical Society last year, on epilepsy, I said: "All we can do generally in the treatment of this disease, is to render less frequent and less severe the attacks; the removal of peripheral irritation makes the case more hopeful, but statistics are not encouraging as to complete recovery, probably due to the establishment of the epileptic habit, which is due to the adjacent brain centres having become irritable and unstable." These statements were severely criticised, my prognosis was said to be too gloomy, and the outlook for epilepsy too discouraging.

Another year's observation and study only confirms my belief more strongly, for epilepsy is, as yet, a Gordian knot for the neurologist and surgeon to untie. Gray, Sachs, Ferrier, Dana, Wilmarth and other authorities have contributed to the literature of epilepsy, clinical observations which sustain my humble opinion.

Surgical interference is justifiable and should be advocated in all cases of traumatic or organic epilepsy, providing sclerosis is not too far advanced.

In focal epilepsy, we cannot predict the results following excision of the localized seat of irritation, first, because conditions more severe than the epilepsy itself may follow removal of the cortical substance; and second, we cannot give assurance of the cessation of the spasms. I have in mind a case to which the first statement applies; a boy, an epileptic, trephined, and portion of cortex removed. The epilepsy ceased, but the boy became an imbecile, and is now an inmate of an institution for feeble-minded children. My second statement is illustrated by another case, a boy, trephined; epilepsy still continues; fits are more severe, and this boy has since been admitted to a feeble-minded institution. We must not overlook the fact that injuries comparatively slight, and which would do little if any damage to the brain of an adult, in a child produce disastrous effects and diffuse sclerosis results. Wilmarth, in his autopsies, has repeatedly demonstrated this fact, and while associated with him I had this so impressed upon me, that I am loth to advise trephining in the epilepsies of childhood, unless taken very early in the history of the case, and even then we cannot offer much hope, for as Wilmarth says in his cases, "My postmortem studies have led me to believe that while considerable injury may be inflicted on the adult brain with no great impairment of the mind resulting, the contrary holds in the child, and brain injury from accident or disease is sure to permanently impair mental growth." Osler likewise pointed out to me, during his study of the cerebral palsies of childhood, the very diffuse formation of blocks of sclerosis, and the improbability of surgical relief.

In his book, he says, "there are several circumstances which militate against the probable success of operations of this kind. When sclerosis exists the area is usually too large for removal and it is only in exceptional instances, we could expect the epilepsy to be relieved. I do not think that in any of the cases which I have reviewed, the anatomical condition offered the slightest possibility of relief from surgical interference."

What then is to be the future of surgical interference in the epilepsy of childhood? We must be guided by the nature of the case; often, no doubt, we can by operating arrest the progress of the disease, perhaps cure. Further, as Sachs says, in the cerebral palsies of childhood, the paralysis which so often proceeds the epilepsy will be the guide for operative procedure by localizing the irritation; the centres should be exposed and be treated in accordance with the special indications of the case.

He is confident that if these cases of infantile cerebral palsies are more generally recognized and if we succeed in checking the tendency to epilepsy in them, the total number of epileptics will be notably diminished.

Defective Sensory Perception.—Operative interference in cases of defective sensory perception, as presented by Starr, in a recent paper on cerebral atrophies of childhood, seems to me, to open up a field for observation for the neurologist; one promising some benefit in preventing, or at least ameliorating, the condition of that great class of defectives, the blind, and the deaf and dumb We all know that many, many of these cases, especially of the deaf and dumb, owe their trouble to cerebral diseases. Diseases which medical treatment has failed to relieve and we cannot but hope that surgery may ultimately find a way to benefit this unfortunate class. Deaf mutism is little understood, and less studied by the neurologist, in fact a thorough etiological study of this prevalent condition from the standpoint of neuro-pathology has not been scientifically undertaken. Through the kindness of Dr. Gillett, Supt. of the Illinois Institution for the Deaf and Dumb, the largest institution of its kind in the world, I have commenced the study of deaf-mutism, and hope to report my progress at the next meeting of this Association.

In conclusion, I would say surgery has its field of usefulness in cerebral diseases of childhood but is limited by the pathology and the degree of success following operations. To scientifically recommend surgical interference, we must be sure of our diagnosis, pathology and permit of extreme limits in our prognosis.

SECTION OF STATE MEDICINE.

First Day—June 7.

Afternoon session—Present, Doctors Benjamin Lee, A. W. Bell, C. F. Ulrich, Francis A. Atkins, Charles Lindsley, J. H. Hamilton, J. W. Hamilton, J. Berrien Lindsley, Irving A. Watson, Laurence F. Flick, Joseph J. Hibbard, Ralph E. Starkweather, Charles H Shepard, Jerome Cochran, Charles McIntyre, Thomas A. Foster, Charles D. Alton, W. L. Schenck, W. S. Davis, R. H. Reed, Delos Fall, S. C. Johnson, Felix Formento, J. T. Reeve, William Bailey, A. Hazelwood, U. O. B. Wingate, Albert L. Gihon, Walter Wyman, T. D. Crothers, Alonzo W. Garlock.

Session called to order at 3:30 o'clock, Dr. Lee in the chair.

Dr. Lee read his address, subject, "The Responsibility of the State and National Government in regard to the Protection of the Purity of the Water Supply."

Dr. Lee introduced his paper by some remarks upon the work of the Section. On motion thanks were returned Dr. Lee.

Report of Committee of School Hygiene was deferred upon motion on account of the absence of chairman.

Dr. J. Hardy Reed read his report of the Committee on Improvement in the Work of the Section.

The chairman asked what was the action of the Society at the morning session in the matter embodied in this report.

Dr. Reed answered that nearly all the provisions recommended in his paper were adopted. He said further that members ought not to be permitted to vote in different Sections. Dr. Hibbard wanted to know how the paying of dues in the Section would prevent the voting in other Sections. Dr. Reed thought the plan suggested would prevent the repeating of votes in various Sections. Dr. Bell said that the adoption of the amendment in the general Society covered the entire matter and thought it would obscure matters to try anything further now.

Dr. Bell moved that the report of the committee be received and the committee dismissed.

Dr. Starkweather seconded the motion, but asked that the committee be continued.

Dr. Reed moved as a substitute that the report be adopted so far as it was in accord with what had been done in the general Society at the morning session.

Seconded by Dr. Hibbard and passed.

The chairman stated that this ended the work of the Section for the day. He stated further that with the consent of the Section, Dr. Bell would read his paper which was down for the next day. Dr. Reed said that if agreeable he would like to present his report on the meat question. Consent was given to Dr. Reed to present the report.

The chair announced as a Committee on Nominations, Dr. Lindsley, of Connecticut, Dr. Starkweather, of Illinois, and Dr. Schenck, of Kansas, and requested that they report at 3 o'clock the following day.

The chair announced that this Section would have to elect an Executive Committee of three to form the Business Committee of the Association. Nominations were called for.

Dr. Starkweather nominated Dr. Lee, Dr. Flick nominated Dr. Davis, of Chicago, and Dr. Reed, of Mansfield, Ohio. Dr. Ulrich asked how it is to be determined who shall serve one, two and three years.

Dr. Starkweather moved that the Secretary cast one ballot in favor of the nominees. Passed.

Chairman asked in what order the names should stand.

Dr. Reed moved that the order be: Dr. Lee, three years; Dr. Davis, two years, and himself one year.

Motion seconded and carried.

Dr. Reed read his paper on the meat question.

Before reading his paper he made a brief statement of the methods practiced in the slaughtering pens. He witnessed the slaughter of unhealthy cattle. The number of inspectors is too small to do the work properly. He said he had carefully watched this.

His paper consisted of a series of resolutions.

It was moved and seconded that the report be received and adopted.

Dr. Hibbard said he had been much interested in the inspection at Kansas City. The inspector at Kansas City said to Dr. Hibbard that he (the inspector) would not publicly make any statement, but would give it privately. He told Dr. Hibbard that two men made the anti-mortem examination or inspection, and that those two men were merely butchers with great experience. That the close inspection was only made in cases reported as suspicious by these two men. Cases that were clearly unhealthy, were condemned and sent to the phosphate department. He said the business itself protected the public somewhat because the firm could not afford to send out bad meat. Dr. Hibbard stated that he himself, after what he had heard and seen had pretty good confidence in the inspection.

Dr. Reed said that only cases in which tuberculosis was suspected were really closely examined. Under the present methods no protection is had against hog cholera. In manufacturing the various things made out of hog's intestines no care is observed. In cleaning the intestines for sausages, they are thrown in a barrel and allowed to remain there until they become so offensive as to be almost unbearable, and are carelessly cleaned out of these barrels. Intestines when cleaned for sausages still contained mucus, and other foul matter. The Bologna sausages are dried instead of smoked. Only two hours are given to smoking. It is such prepared meat as this that causes poisoning. The hams are cured in four or five days. They inject the hams with pyroxilic acid and other matters. The packing house ham has a peculiar sourish smell. It is important that there should be a more perfect method of inspection. The hogs are drawn up by the legs, stuck, scraped, all of which is done in a few moments.

Dr. Jerome Cochran said that this information is apt to put us out of the humor of eating meat and he favored the motion.

Dr. Fall asked Dr. Reed if the microscopic examination is not made solely to discover the trichina.

Dr. Lee asked if sheep are taken through the packing house.

Dr. Reed answered they were.

Dr. Hibbard said he thought it very desirable to appoint a committee to expose these deceptions if they are practiced.

Dr. Flick spoke in favor of the resolution.

Dr. Schenck said he entirely agreed with Dr. Reed. He said the greed for money was apt to make the meat men indifferent to the healthfulness of the meat. He thought, however, that the great difficulty would be that the committee would have no powers.

Dr. Cochran said it would be well to appoint a committee of three who are to report to-morrow. He suggested that Drs. Reed, Schenck and Hibbard be placed on the committee.

Dr. Reed said the cases may not be injurious but it is not right that inferior meat be sold as first class.

Dr. Starkweather said he thought it a serious thing to give the enemies of the food problem too much information.

Dr. Lindsley agreed with Dr. Starkweather.

Dr. Bell was called to the chair and Dr. Lee took the floor. He said it was important to consider the question carefully. As sanitarians we have no right to inquire whether a thing is of full value. We are only concerned with its healthfulness.

Dr. Cochran moved that the resolutions be referred to a committee.

Motion passed.

Dr. Schenck asked that he be not named on the committee. Committee, Drs. Reed, Starkweather, and Prof. Fall. Prof. Fall asked to be relieved from service on the committee and Dr. Cochran was appointed in his place. Adjourned at 6 p.m.

June 8, 1892.

Meeting called to order by Dr. Lee, Chairman.

Report of Nominating Committee was called for. The chairman being absent Dr. Starkweather reported as follows:

For Chairman, Dr. Charles A. Lindsley, of Connecticut, for Secretary, Dr. Samuel P. Duffield, of Detroit, Mich.

It was moved and seconded that the secretary cast the ballot for the election of these gentlemen. The motion was carried and the secretary cast the ballot.

The report on the meat question was called for.

Dr. Reed read the report.

He suggested that the committee to be appointed under the report, if any is to be appointed, ought to be comprised of members living near the slaughter houses.

Dr. Cochran expressed a desire that the report be well discussed. He said we ought to consider the question carefully. The United States government is concerned, large interests are involved. For this reason we should go carefully and be certain of our facts before acting. He said he had his doubts about the wisdom of making an inspection at all. There is filth and filth, much filth that is objectionable as a matter of sentiment, is not objectionable as a matter of health. The first question is, what makes beef products unwholesome? This must be determined first. Until we know what to do we ought to act carefully.

Dr. Reed replied: The part which the government plays ought not to influence us. We are here as sanitarians. The work is new and defective, hence we ought to look into it and give our advice as sanitarians and our aid. We should investigate the matter and see how the law is carried out, and in what way the law might be enforced.

Dr. Hibbard said that he does not see how we can proceed in an investigation without having something to base an investigation on. The animal that is slightly unhealthy may nevertheless be healthy food. He was willing to go so far in this matter as to look for further information on the subject, but thought it would be better to be certain of the facts before going any farther.

Rr. Reed said there must be some misunderstanding on the subject. The object of the resolution is to get information. The government assumes that a diseased animal is unhealthy. Now, the question is how far they can carry that assumption.

Dr. Gihon asked that the report be read. This was done.

Dr. Gihon then asked who would pay the expenses of the committee.

Dr. Reed answered that no one was asked for pay.

Dr. Gihon—Then the committee will merely be on paper.

Dr. Reed—I refer the members to the report of the Committee on Hygiene which cost about $700.00, and which was made without any cost to the Section. This can be done the same way. The meat question is a public one and belongs to us legitimately as sanitarians.

Dr. Greenlief, of Kentucky, said it made some difference whether the disease was local or general.

The Chairman said Dr. Greenlief was off the subject.

A vote was taken on the resolutions and they passed by a rising vote 13 in favor, and 5 against them.

Dr. Lee asked for an expression as to how many should go on the committee.

It was decided to place the number at five.

Dr. A. N. Bell, of Brooklyn, read a paper on "Needful Legislation for the Protection of Human Life."

Dr. Comegys opened the discussion. He said that all Dr. Bell said about the necessity of disinfecting ships,etc., must be admitted, but he differed somewhat with Dr. Bell as to the means to be employed to bring about the desired result. The question is, can they be disinfected by the State? It is a question of executive power. Which would be most efficient, a department of Public Health, or some other department, such as the department of war? The question should be left with the medical men. The medical profession is in the best position to know what is needed in preventive medicine. The quarantine department cannot cope with this entire question. The Board of Health has been a failure in this matter. Public welfare is closely connected with the practice of medicine. We need a Department of Public Health. It would bring about reform in medical education.

Dr. Formento said that while he agreed with Dr. Bell in most points, there are some things he cannot allow to go by without a protest. He believes that State Boards of Health can in themselves cope with the question. New Orleans has kept out disease since 1878 on her own resources.

Dr. Cochran said he had a few ideas upon this question which he desired to present. He would be glad if a law could be passed to create a Department of Public Health. He did not believe that Congress would even give the matter serious consideration at present. We might do better by asking less. It might be well to ask for a Commissioner of Health. He said he had reason to believe that a bill could be passed creating the office. He would suggest that if there is ever a Commissioner of Public Health, he ought to annually call a conference of officers of Boards of Health to consult them. There has been a great tendency to interfere with the functions of State Boards of Health.

Dr. Wyman said that if it is thought there are no quarantine laws he felt called upon to explain the situation. There are eight quarantine stations at present, that is, eight national stations. Most of these are or are becoming places of refuge. The relations between the national and local stations are most cordial. So great is the fear of yellow fever in the South that during hot weather the southern cities require all ships whether infected or not to be disinfected if they come from questionable ports. A bill has been introduced to perfect the quarantine laws ;this will not intrench upon the Boards of Health.

Dr. Comegys desired to say further that nothing has been done to interfere with the quarantine department or the Boards of Health, in the effort that has been made to secure the appointment of a Commissioner of Health. He then read a circular on the subject.

Dr. Bell, in closing the debate, said he did not want to interfere with the Boards of Health, but to better organize them. He wants to arraign our government for neglecting the health of the people. We need a National Health Department that will coördinate with State Boards.

On motion, Dr. Bell's paper was referred to the Committee on printing.

In addition to the names recorded before as having been registered there are those of A. J. Fuller and T. B. Greenley.

Dr. Crothers read his paper on "The Sanitary Side of the Drinking Question."

Dr. Cochran in discussing Dr. Crothers' paper said he thought the suggestions made in the paper were well worthy of consideration.

Dr. Hibbard said he approved of the beginning and ending of the paper but condemned the middle. It is a great mistake to suppose that drunkards can be cured by imprisonment. There is some benefit in imprisonment however. He does not believe in abolishing saloons, but in taxing them in order that good would be accomplished. Reformatories ought to be supported by this tax.

Dr. Cochran said further, that there was a great deal in the paper that is untenable, but the general trend of the paper he endorsed.

Dr. G. H. Hamilton said that this subject had attracted his attention for some time. He believes with the reader, that punishment or imprisonment does injury instead of good. Punishment for intoxication is wrong. The proper method is that suggested by the paper. He cannot approve of granting licenses.

Dr. Bell said he was very much gratified to hear Dr. Crothers admit there should be any punishment for drunkards.

Dr. Greenlief said he believed that too much importance was attached to the hereditary. He believed that it is an acquired taste or disease.

Dr. Starkweather called attention to the fact that Dr. Duffield was not registered.

Dr. Flick moved that the part of the report of the Committee on Nominations be referred back to the committee, dealing with the nomination for secretary. Passed.

The report of the Committee on Nominations states that Dr. Lindsley was absent and was not consulted about the nominations.

On motion adjourned.

JUNE 9, 1892.

Section called to order by Dr. Lee at 2:30 P.M.

The chair called for the report of the Nominating Committee.

Dr. Starkweather reported the name of the nominee, for the Secretaryship, to be Dr. Samuel P. Duffield, of Detroit. Dr. Duffield was elected.

The next business called for the paper of Dr. Shepard, of Brooklyn, on "The Public Baths as a Preventive of Disease."

Dr. Lee called Dr. Bell to the chair and took the floor. He said he wanted to speak of the Turkish bath as a therapeutic agent. The Turkish bath is such an agent because it is a hygienic agent. It will probably be a long time before our government will introduce public Turkish baths,but it is only a step in advance of the baths already instituted and will come.

Dr. Bell said there should be a distinction between the Turkish bath as an indiscriminated agent, and as a special agent. There should be a discrimination in its use.

Dr. Shepard in closing, said the danger from the Turkish bath would be obviated by proper education.

Dr. Ulrich said that Turkish baths should be associated with other baths and treated as a branch.

Dr. Flick spoke on "The Voluntary Association for the Prevention of Tuberculosis."

Dr. Duffield said that the question of contagion underlaid the subject under discussion. He thought that climate ought not to be overlooked. He thought cold played an important part in the etiology of the disease.

Dr. Ulrich said the remarks of the gentleman who had just spoken were very apropos, but in this Section we can only take advantage of those things at our command. Poor people cannot take advantage of a change of climate. There is great carelessness in the distribution of tubercular sputa. In this there is need of education.

Dr. Cochran said: I did not hear the paper read and possibly the questions I will ask have been answered. I would like to know what the members of this Section consider the principal avenue of introduction into the system of tuberculosis.

Dr. Cutter said he believed it was the object of the Section to get the views of all the members. He believed the principal avenue of introduction to be by the stomach.

On motion, adjourned until June 10, at 9 A.M.

JUNE 10, 1892.

Meeting called to order by Dr. Cochran in the absence of Dr. Lee.

A paper on "Kumyss" by Dr. Mount Bleyer, of New York City, was read by its title and referred to the Committee on Publication.

Dr. Francis H. Atkins, of New Mexico, read a paper on "A Bird's Eye View of New Mexico."

Committee on meat packing establishments, Drs. R. Harvey Reed, Mansfield, Ohio; J. F. Hibbard, Richmond, Indiana; W. L. Schenck, Topeka, Kansas; R. E. Starkweather, Chicago, Ill.; U. O. B. Wingate, Milwaukee, Wis.

Paper of Dr. Atkins referred to the Committee on Publication.

Resolutions were offered regarding the pollution of sewers; they were read and laid upon the table.

It was moved and seconded, that the officers of this Section be instructed to confer with the Section on Dietetics and Medical Jurisprudence with a view of consolidating the three Sections, and report at the next meeting.

Motion to adjourn *sine die*, carried.

LAURENCE F. FLICK, *Secretary*.

BENJAMIN LEE, M.D., *President*.

REPORT OF THE COMMITTEE ON IMPROVEMENT IN THE WORK OF THE SECTION.

Read before the Section of State Medicine, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

Mr. Chairman and Gentlemen of the Section:—Your committee appointed last year to report the best plan to improve the Section work of our Association, begs leave to make the following report:

WHEREAS, The real work of the American Medical Association has been and should continue to be done in the various Sections of the same; and,

WHEREAS, With the present arrangements the time for Sectional work is now so limited, in comparison with the amount of work to be done, as to greatly interfere with the practical accomplishment of the same; and,

WHEREAS, A great deal of unnecessary time is spent each year in the general session of the Association in legislative work, which is of no value or importance to anyone in the study of the science of his profession; therefore be it

Resolved, That it is the sense of this committee: 1. That the time devoted to Sectional work should be increased, and that the time now allotted to the general session of the Association should be limited not to exceed one hour each day, and that that hour be from 12 noon to 1 P.M.

2. *Resolved*, That we believe it to be to the interest of the Association that each Section should be to the Association as the States are to the Union, and that each Section should continue the election of its own officers and manage its own business, and report the same to the Association as the latter may require.

3. *Resolved*, That each Section have the privilege of preparing and adopting a constitution and by-laws for its own special government, and that its officers shall consist of a Chairman, vice-Chairman, Secretary and Executive Committee.

4. *Resolved*, That in selecting these officers the chairman shall appoint a nominating committee each year, consisting of three persons, no two of which shall be from the same State, territory or general division of the United States, and that each member of said committee shall place in nomination a complete ticket, covering all the officers to be elected, and that the Section choose by ballot their officers from the three tickets thus presented to them at each annual meeting.

5. *Resolved*, That the Executive Committee shall consist of three persons, one of which shall serve for one year, one for two years, and one for three years, and thereafter one new member shall be added each year, which shall consist of the retiring chairman of said Section.

6. *Resolved*, That the Executive Committees of all the Sections shall constitute the Advisory Council of the American Medical Association, and shall be empowered to nominate its officers at each annual meeting, and recommend for adoption such policy, changes, alterations and improvements for the management of the Association as they may consider for the best interest of all concerned.

7. *Resolved*, That said Advisory Council shall be empowered to elect its own chairman and secretary, and shall be required to make a report to the Association each year, which shall contain the officers nominated, and such other advice as they may see proper to give.

8. *Resolved*, That the members of the American Medical Association shall be required to pay their dues to the treasurer of the Section to which they belong, allowing them to select for themselves which Section they shall register in, which shall be the only Section in which they shall have voice in the election of the officers or any other Sectional work, but may attend other Sections, and read or discuss papers in the same at the option of said Section.

9. *Resolved*, That it shall be the duty of the Section treasurer to collect the annual dues for his Section, which shall be fixed by the Association, and report the same to the general secretary of the Association and turn over all money so collected to the general treasurer of the Association, taking his receipt for the same.

10. *Resolved*, That the custom of delivering general addresses to the entire Association be dispensed with as obsolete and valueless, and that only such work be enacted in the general session of the Association as is of special importance to the Association at large, and that all scientific work be confined to the Section to which it belongs.

11. *Resolved*, That all papers read before any Section thereof, shall be referred to the Executive Committee of the same, which shall have the power to reject such papers as they may elect and consider to the interest of the Section, and the Association at large.

12. *Resolved*, That the entire work of the Association be published in journal form as heretofore, but that each Section be furnished in reprint the special work done in said Section, including the papers and discussions of the same, which shall be neatly bound in uniform size and style, in paper backs and furnish free to each member, who shall have the privilege of purchasing as many extra copies as he may desire at a mere nominal price, which shall only cover the actual expense of preparing the same, and that those desiring better binding can be accommodated by paying extra amount necessary for the same.

All of which is very respectfully submitted.

R. HARVEY REED, *Chairman*.

REPORT OF THE SPECIAL COMMITTEE TO DEVISE A PLAN TO PURSUE IN THE INSPECTION OF THE PACKING HOUSES OF THIS COUNTRY.

Read in the Section of State Medicine at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, June, 1892.

Your Committee beg leave to report that they would respectfully recommend:

1. That a committee of not less than three nor more than five be appointed by the chairman of this Section, who shall conduct an inspection of the

packing houses of this country, which inspection shall be conducted solely in the interests of the public health, and at the same time shall observe that due care be taken not to unnecessarily interfere with the commercial interests of the same.

2. That this committee be instructed to especially investigate the protection provided against the marketing of trichinous or other diseased meat.

3. That this committee shall be instructed to use all practical diligence to obtain the coöperation of the Bureau of Animal Industry and the management of the various Abbatairs in question, to secure all the general and practical information possible regarding this important question and report the same to this Section.

4. That the preamble and resolution offered by Dr. R. Harvey Reed on "The Meat Problem of this Country" be laid upon the table until next year.

Very respectfully submitted.

R. Harvey Reed, Chairman.
Ralph E. Starkweather.
Jerome Cochran.

Dr. Cochran favors the plan outlined in the report of the committee if an inspection is to be made, but has grave doubts as to the propriety of making any inspection at all.

THE MEAT PROBLEM OF THIS COUNTRY.

Whereas, This is preëminently a meat-eating country, and that the greater portion of meat supplied our citizens is now slaughtered at the so-called "packing houses" of this country and transported, by rail or otherwise, in various forms, to the numerous markets of our cities; and,

Whereas, This trade has become so enormous that in one year alone 1,750,000 hogs, and 750,000 cattle, besides calves and sheep, were slaughtered and shipped to various parts of our country, as well as to foreign countries, by one firm alone; and,

Whereas, The Federal Government, on March 3, 1891, enacted a law to provide for the inspection of live cattle, hogs, and carcasses and products thereof, which are the subjects of interstate commerce, and for other purposes, and have placed this inspection in the care of a bureau, under the Department of Agriculture (a copy of which law is herewith attached, together with the rules and regulations for the inspection of live stock and their products, issued by Secretary Rusk); and,

Whereas, These inspections have largely been confined to the export trade, and the meat so exported sent out under an official seal of this government; and,

Whereas, It has come to our notice that said meat so imported to foreign countries has been found to be diseased, saying nothing of the meat that has not undergone inspection and which has been sold to the citizens of this country; and,

Whereas, It is claimed by the Department of Agriculture that the microscopists, who make these examinations, are only expected to examine 50 animals, of which they are required to make two examinations, cut their own sections and make their reports; and,

Whereas, As by personal inspection by the writer it has been ascertained to his personal knowledge that 10 microscopists were required to examine 800 hogs in a single day, on which two examinations had to be made, making in all 1,600 examinations, or an average of 160 microscopic examinations and reports for each microscopist; and,

Whereas, The anti- and post-mortem examination of over 1,200 cattle, 800 hogs, 500 to 600 sheep, and as many calves, were required to be made by four veterinary surgeons; Therefore, be it

Resolved, That this Section consider it a practical impossibility to make this number of inspections with accuracy by the number of examiners employed; and that it is detrimental to the public health to permit of the wholesale slaughter of animals and the general sale of such meat in the manner in which it is now done, without competent and complete inspections; and, further be it

Resolved, That it is not to the interest of the government to allow its brand to be placed on meat which has not been thoroughly inspected, in such a manner as to bear the most critical examination that may afterwards be made; and, further be it

Resolved, That this Section appoint a committee of no less than three or more than five, who are willing to assume this work, and that they be requested to make a personal investigation of the packing houses of this country, the manner of inspection, the kind of meat killed, its classification, the manner of shipping it, the manner in which it is prepared and such other information as may be of public interest, and report the same to this Section.

Very respectfully submitted,

Mansfield, O. R. Harvey Reed, M.D.

REGULATIONS FOR THE INSPECTION OF LIVE STOCK AND THEIR PRODUCTS.

U. S. Dept. of Agriculture, Office of the Secretary,
Washington, D. C., March 25, 1891.

The following rules and regulations, being additional to the rules and regulations heretofore made under the act of Congress approved August 30, 1890, are hereby prescribed for the inspection of live cattle, hogs, and their carcasses, by virtue of the authority conferred upon the Secretary of Agriculture under the provisions of the act of Congress approved March 3, 1891, entitled "An act to provide for the inspection of live cattle, hogs, and the carcasses and products thereof which are the subjects of interstate commerce, and for other purposes."

1. *Export Cattle Inspection*. The order and regulations providing for the inspection of export cattle and sheep, made October 20, 1890, under the provisions of section 10 of the act of Congress approved August 30, 1890, are hereby continued in full force and effect, the same as if made under the provisions of the act of March 3, 1891, and all exporters, to secure clearance for their shipments of cattle, must comply strictly with the said regulations.

2. *Meat Inspection*. The proprietors of slaughter-houses, canning, salting, packing or rendering establishments, engaged in the slaughter of cattle, sheep or swine, the carcasses or products of which are to become subjects of interstate or foreign commerce, will make application to the Secretary of Agriculture for inspection of said animals and their products.

3. The said application must be in writing, addressed to the Secretary of Agriculture, Washington, D. C., and shall state the location and address of the slaughter-house or other establishment, the kind of animals slaugtered, the estimated number of animals slaughtered per week, and the character and quantity of the products to go into the interstate or foreign commerce from said establishment; and the said applicant in his application shall agree to conform strictly with all regulations or order that may be made by the Secretary of Agriculture for carrying on the work of inspection at such establishment.

4. The Secretary of Agriculture, upon receipt of said application and after consideration thereof, will give said establishment an official number, by which all its inspected products will thereafter be known, and this number will be used both by the inspectors of the Department of Agriculture, and by the owners of said establishment, to mark the products of the establishment as hereinafter prescribed.

5. The Secretary of Agriculture will appoint and designate a veterinary inspector to take charge of the examination and inspection of animals and their products for each establishment which has been officially numbered, as prescribed by rule 3, and will detail to such inspector such assistants or other employees as may be necessary to properly carry on the work of inspection at said establishment. The inspector appointed, and all employees under his direction, shall have full and free access at all times to all parts of the building or buildings used in the slaughter of live animals and the conversion of their carcasses into food products.

6. The veterinary inspector in charge of said establishment will carefully inspect all animals in the pens of said establishment about to be slaughtered, and no animal shall be allowed to pass to the slaughtering room until it has been so inspected. Whenever any animal is found on said inspection to be diseased, said animal shall thereupon be condemned by the inspector, and the owner of the same shall at once remove it from the premises and dispose of it in such manner as may be provided by the laws of the State in which said animal is located.

7. The veterinary inspector or his assistant shall carefully inspect at time of slaughter all animals slaughtered at said establishment and make a post-mortem report of the same

to the Department. Should the carcass of any animal, on said post-mortem examination, be found to be diseased and unfit for human food, the said carcass shall at once be removed from said establishment under the supervision of the inspector and be disposed of in the manner provided by the laws of the State where slaughtered. Any owner of any establishment in which inspections are being made under the provisions of the act of March 3, 1891, who shall wilfully cause or permit any animal which, upon inspection, has been found to be diseased to remain on said premises beyond the time allowed by the inspector in charge for its removal, shall forfeit his right to inspection, and said establishment will, for such time as the Secretary may direct, be refused certificates of inspection upon its products.

8. The carcasses of cattle which leave said establishment as dressed beef will be stamped by said inspector with a numbered stamp issued by the Department of Agriculture, and a record of the same will be sent to the Department at Washington.

9. Each and every article of food products made from the carcasses of animals inspected will be labeled or marked in such manner as the owner of said establishment may direct; said label, however, must bear the official number of the establishment from which said product came and also contain a statement that the same has been inspected under the provisions of the act of March 3, 1891.

A copy of said label must be filed at the Department of Agriculture, Washington, D. C., and, after filing, said label will become the mark of identification showing that the products to which it has been attached have been inspected, as provided by these rules and regulations, and any person who shall forge, counterfeit, alter, or deface said label will be prosecuted under the penalty clause of section 4 of the act of March 3, 1891.

Each and every package to be shipped from said establishment to any foreign country must have printed or stenciled on the side or on the top, by the packer or exporter, the following:

FOR EXPORT.

(*a*) Official number of establishment.
(*b*) Location of factory.
(*c*) Number of pieces or pounds.
(*d*) Trade-mark.

In case said package is for transportation to some other State or Territory or to the District of Columbia, in place of the words "for export" the words "INTERSTATE TRADE" shall be substituted.

The letters and figures in the above print shall be of the following dimensions: The letters in the words "For Export" or the words "Interstate Trade" shall not be less than three-fourths of an inch in length, and the other letters and figures not less than one-half inch in length. The letters and figures affixed to said package shall be legible and shall be in such proportion and of such color as the inspector of the Department of Agriculture may designate.

10. The inspector of the Department of Agriculture in charge of said establishment, being satisfied that the articles in said packages came from animals inspected by him, and that they are wholesome, sound, and fit for human food, shall affix to the top of said packages meat inspection stamps to be furnished by the Department of Agriculture, said stamps bearing serial numbers, and the inspector will write on said stamps the date of inspection.

The stamp must be securely affixed by paste and tacks in such a way as to be easily read when the package is standing on its bottom. Not less than five tacks shall be driven through each stamp, one at each corner and one in the middle of the stamp.

The stamp having been affixed, it must be immediately canceled. For this purpose the inspector will use a stencil plate of brass or copper, in which will be cut five parallel waved lines long enough to extend beyond each side of the stamp on the wood of the package. At the top of said stencil will be cut the name of the inspector and at the bottom of said stencil will be cut the district in which the inspection is made. The imprinting from this plate must be with blacking or other durable material, over and across the stamp, and in such a manner as not to deface the reading matter on the stamp, that is, so as not to daub and make it illegible. The stamp having been affixed and canceled, it must immediately be covered with a coating of transparent varnish or other substance. Orders for stamps must be made by the inspector on the Chief of the Bureau of Animal Industry.

11. Whenever any package of meat products bearing the stamp of inspection shall have been opened and its contents removed for sale the stamp on said package must be effaced and obliterated from the package.

12. Reports of the work of inspection carried on in every establishment will be forwarded to the Department by the inspector in charge, on such blank forms and in such manner as will be specified in "instructions to inspectors of slaughtering establishments."

13. *Swine.*—The inspection of swine for export or interstate trade will be conducted in the same manner as prescribed in the foregoing rules, with the addition, however, that a microscopic examination for trichina will be required for all swine products.

14. When the slaughtered hog is passed into the cooling room of said establishment, the veterinary inspector in charge, or his assistants, will take from each hog two samples of muscle, one from the "pillar of the diaphragm" and the other from another part of the body, and said samples will be put in a self-locking tin box and a numbered tag will be placed upon the hog from which said samples have been taken and a duplicate number of said tag will be placed in the box with said samples. The boxes containing the samples from the hogs in the cooling room, so tagged, will be taken to the microscopist for such establishment, who shall thereupon make a microscopic examination of each box containing samples, and shall furnish a written report to the inspector in charge of the cooling room, giving the result of said microscopic examination, together with the numbers of the hogs from which samples have been examined.

15. All hogs reported by the microscopist to the inspector in charge of the cooling room to be affected with trichina will at once be removed from said cooling room of said establishment under the supervision of said inspector or one of his deputies, and be disposed of by the owner in such a manner as may be required by the laws of the State where said factory is situated.

16. The inspector in charge of the slaughtering or other establishment will issue a certificate of inspection for all carcasses of animals or the food products thereof which are to be exported into foreign countries, which certificate will cite the number of the factory, the name of the owner or owners operating the same, the date of inspection, and the name of the consignee and country to which said articles are to be exported. Said certificate will also contain the numbers of the stamps attached to the articles to be exported. One certificate only will be issued for each consignment. The certificates will be issued in serial numbers and in triplicate form. One copy thereof will be delivered to the consignor of such shipment, one copy will be attached to the invoice or shipping bill to accompany the same and be delivered by the transportation companies to the chief officer of the vessel upon which said consignment is to be transported, and the third copy will be forwarded to the Department of Agriculture for filing therein. J. M. RUSK,
Secretary.

An act to provide for the inspection of live cattle, hogs, and the carcasses and products thereof which are the subjects of interstate commerce, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Secretary of Agriculture shall cause to be made a careful inspection of all cattle intended for export to foreign countries from the United States, at such times and places, and in such manner, as he may think proper, with a view to ascertain whether such cattle are free from disease; and for this purpose he may appoint inspectors, who shall be authorized to give an official certificate clearly stating the condition in which such animals are found, and no clearance shall be given any vessel having on board cattle for exportation to a foreign country unless the owner or shipper of such cattle has a certificate from the inspector herein authorized to be appointed, stating that said cattle are sound and free from disease.

SEC. 2. That the Secretary of Agriculture shall also cause to be made a careful inspection of all live cattle the meat of which is intended for exportation to any foreign country, at such times and places, and in such manner, as he may think proper, with a view to ascertain whether said cattle are free from disease and their meat sound and wholesome, and may appoint inspectors, who shall be authorized to give an official certificate clearly stating the condition in which such cattle and meat are found, and no clearance shall be given to any vessel having on board any fresh beef for exportation to and sale in a foreign country from any port of the United States until the owner or shipper shall obtain from an inspector appointed under the provisions of this act such certificate.

Sec. 3. The Secretary of Agriculture shall cause to be inspected, prior to their slaughter, all cattle, sheep, and hogs which are subjects of interstate commerce and which are about to be slaughtered at slaughter-houses, canning, salting, packing or rendering establishments in any State or Territory, the carcasses or products of which are to be transported and sold for human consumption, in any other State or Territory or the District of Calumbia, and in addition to the aforesaid inspection, there may be made in all cases where the Secretary of Agriculture may deem necessary or expedient, under the rules and regulations to be by him prescribed, a post-mortem examination of the carcasses of all cattle, sheep, and hogs about to be prepared for human consumption at any slaughter-house, canning, salting, packing or rendering establishment in any State or Territory, or the District of Columbia, which are the subjects of interstate commerce.

Sec. 4. That said examination shall be made in the manner provided by rules and regulations to be prescribed by the Secretary of Agriculture, and after said examination the carcasses and products of all cattle, sheep, and swine found to be free of disease, and wholesome, sound, and fit for human food, shall be marked, stamped, or labeled for identification as may be provided by said rules aud regulations of the Secretary of Agriculture.

Any person who shall forge, counterfeit, or knowingly and wrongfully alter, deface, or destroy any of the marks, stamps, or other devices provided for in the regulations of the Secretary of Agriculture, of any such carcasses or their products, or who shall forge, counterfeit, or knowingly and wrongfully alter, deface, or destroy any certificate provided for in said regulations, shall be deemed guilty of a misdemeanor, and on conviction thereof shall be punished by a fine not exceeding one thousand dollars, or imprisonment not exceeding one year, or by both said *punishments, in the* discretion of the court.

Sec. 5. That it shall be unlawful for any persons to transport from one State or Territory or the District of Columbia, into any other State or Territory, or the District of Columbia, or for any person to deliver to another for transportation from one State or Territory or the District of Columbia into another State or Territory or the District of Columbia the carcasses of any cattle, sheep, or swine, or the food products thereof, which have been examined in accordance with the provisions of sections three and four of this act, and which on said examination have been declared by the inspector making the same to be unsound or diseased. Any person violating the provisions of this section shall be deemed guilty of a misdemeanor and punished for each offense as provided in section four of this act.

Sec. 6. That the inspectors provided for in sections one and two of this act shall be authorized to give official certificates of the sound and wholesome condition of the cattle, sheep, and swine, their carcasses and products described in sections three and four of this act, and one copy of every certificate granted under the provisions of this act, shall be filed in the Department of Agriculture, another copy shall be delivered to the owner or shipper, and when the cattle, sheep, and swine, or their carcasses and products are sent abroad, a *third copy* shall be delivered to the chief officer of the vsesel on which the shipment shall be made.

Sec. 7. That none of the provisions of this act shall be so construed as to apply to any cattle, sheep, or swine slaughtered by any farmer upon his farm, which may be transported from one State or Territory or the District of Columbia into another State or Territory or the District of Columbia: *Provided, however*, That if the carcasses of such cattle, sheep, or swine go to any packing or canning establishment and are intended for transportation to any other State or Territory or the District of Columbia as hereinbefore provided, they shall there be subject to the post-mortem examination provided for in sections three and four of this act.

Approved, March 3, 1891.

Dr. Holmes' Birthday.— August 29 passed by quietly with the venerable Autocrat. As compared with some of his birthdays, since he left the eightieth milestone behind, the day was uneventful. The health of Our Poet, physical and mental, has continued fairly comfortable, with the exception that the impairment of his eyesight prevents him from doing some forms of work that might be useful to himself and others.

EARLY NATIONAL LEGISLATION ON THE SUBJECT OF QUARANTINE.

BY STEPHEN SMITH, M.D.,

OF NEW YORK

(Continued from page 378.)

The Fourth Congress met at Philadelphia, December, 1795, at the close of one of the most alarming and widespread epidemics of yellow fever which had as yet been known. The conflicting opinions and acts of different State and municipal authorities in the adoption and enforcement of measures for preventing the importation and spread of yellow fever had excited much public comment. The fever was believed to be imported, and existing quarantines were regarded as inefficient, owing to a want of power on the part of the States to enforce their regulations. The questions which were raised in Congress were twofold, viz.: 1. Should not the establishment and management of quarantines be exclusively the duty of the General Government, under the provision of the Constitution empowering Congress "to regulate commerce?" 2. Is not a quarantine a police regulation of the State or municipality, and hence quite outside of this provision of the Constitution?

It is now a matter of great interest to understand the opinions of those who took part in thé first discussion of the relations of the General and the State Governments in the establishment and administration of maritime quarantine. A motion was made in the First Congress, which sat in New York, looking to the establishment of health offices in the several ports of the Union, but the exact purport of the motion was not known. The following were the proceedings, as given in the Journal of Congress:

"*Thursday, December* 16, 1790. A petition of the merchants and other inhabitants of Baltimore was presented to the House and read, praying that a health office may be established, or other provision made by law, for protecting them from infectious and epidemical diseases brought by passengers and others arriving from foreign countries.

"*Friday, December* 17, 1790. *Ordered*, That the petition of the merchants and other inhabitants of the town of Baltimore, which was presented yesterday, be referred to Mr. Seney, Mr. Vining and Mr. Parker; that they do examine the matter thereof and report the same, with their opinion thereupon, to the House.

"*Tuesday, December* 21, 1790. Mr. Seney, from the committee to whom was referred the memorial of sundry inhabitants of the town of Baltimore, praying the establishment of a health office, made a report, which was twice read and agreed to by the House, as followeth:

"Your committee have had under consideration the subject-matter of said memorial, and are firmly persuaded that the same highly merits the attention of Congress. But being convinced that the regulation prayed by the memorialists is not only essential for the port aforesaid, but for all others into which considerable imports are made, are of opinion that a law ought to be passed with general provisions in this respect.

"*Ordered*, That a bill or bills be brought in pursuant to the said report, and that Mr. Lawrence, of New York, Mr. Seney, of Maryland, Fitzsimmons, of Virginia, Vining, of Delaware, and Goodhue, of Massachusetts, be such committee."

There is no evidence that this committee reported, but the inference is that the petitioners contemplated the establishment of quarantines under national regulations and supervision, and that the project received the sanction of the first committee appointed to consider the petition.

The first representative who moved in the matter was from the State of Maryland, and the measure which he proposed was designed to place the quarantine systems of the United States entirely under the direction of the President, who at that time was General Washington. From the annals of Congress it appears that on the 28th of April, 1796, Hon. Samuel Smith, of Maryland, proposed a resolution to the following effect, which was referred to the Committee of Commerce and Manufacture to report thereon:

"*Resolved*, That the President of the United States be authorized to direct such quarantine to be performed on all vessels from foreign countries arriving at the ports of the United States as he shall judge necessary."

The committee consisted of the following members: Goodhue, of Massachusetts; Bourne, of Rhode Island; Livingston, of New York; Swanwick, of Pennsylvania; Smith, of Maryland; Parker, of Virginia, Smith, of South Carolina.

May 7, 1796, the committee reported a bill to regulate quarantine, which was read twice, and referred to a Committee of the Whole. It was as follows:

"*Be it enacted, etc.*, That the President of the United States be, and is hereby, authorized to direct at what place or station in the vicinity of the respective ports of entry within the United States, and for what duration and particular periods of time, vessels arriving from foreign ports and places may be directed to perform quarantine.

"*Be it enacted, etc.*, That the President of the United States be, and is hereby, authorized to direct the revenue officers, and the officers commanding ports and revenue cutters, to aid in the execution of quarantine, and also the execution of the health laws of the States, respectively, in such manner as may to him appear necessary."

On May 11, 1796, on motion of Mr. S. Smith, of Maryland, the House resolved itself into a Committee of the Whole, on the bill regulating quarantine.

Mr. Heister, of Pennsylvania, objected to the principle of the bill, as it proposed to take power from individual States to regulate what respected the health of their citizens, and to place it in the President of the United States. He thought the measure would be attended with very great inconvenience. Many States lay very distant from the seat of government, and before information could be given to the President of the apprehension of any pestilence being introduced, and his answer received, the disease might be introduced into the country and great havoc made among the citizens. It appeared to him that the government of each individual State was better calculated to regulate quarantine than the general government, because upon the spot. And if the power was to be transferred from the President to the collectors at each port (that he conceived must be the case), it would put a vast deal too much power in their hands.

Mr. Smith, of Maryland, said that each individual State had, or might have, its own health laws, but the performing of quarantine was in the direction of the general government. The President ought to be empowered to designate the place where vessels should perform quarantine, to enforce the performance, and to determine at what time of the year it should commence and end. It ought, he believed, to commence at the present time.

Mr. Kittera, of Pennsylvania, understood that each independent State had a right to legislate on this subject for itself; and if they had no regulations on the subject it was because they had not felt the want of them. He believed that each State understood its own concerns better than the general government, and therefore the regulation might safely be left with them.

Mr. Smith, of Maryland, denied that there was any authority in the State governments to regulate quarantine. They could not command the officer of a port to use force to prevent a vessel entering their ports; the authority over him was in the general government.

Mr. Milledge, of Georgia, opposed the bill. He said the State from which he came was in the habit of regulating quarantine, and that it would be attended with many inconveniences, if the power was to be placed in the general government, to the State which he represented; on account of its distance, it would be particularly objectionable.

Mr. Giles, of Virginia, said that self-preservation justified every State in taking means to prevent the introduction of disease among its citizens, and he thought the bill unnecessary.

Mr. Smith, of South Carolina, said the Constitution did not give to the State governments the power of stopping vessels from coming into their ports.

May 12.—Mr. Heister, of Pennsylvania, moved to strike out the first section. It appeared to him as if it would be taking the power of regulating quarantine from the State governments and placing it in the hands of the collectors at different ports; and, as he believed the collectors were interested in proportion to the quantity of goods imported, the health of our citizens and the interest of the collectors would be placed in opposition to each other.

Mr. Bourne, of Rhode Island, hoped the motion would not be agreed to. He thought it a necessary regulation. No inconvenience, it was true, had occurred in the State he represented, but he believed they were liable to have inconveniences from the want of such a law as this. By the aid of custom-house officers, who had concurred with the State, they had been able to effect every necessary regulation; but if these officers had refused them aid, they could not have stopped vessels with infectious diseases from coming into port—it being of the nature of a commercial regulation, to which, by the Constitution, Congress alone were competent. Without the first clause there would be a radical defect in the bill.

Mr. Swanwick, of Pennsylvania, said if the section were struck out the bill would have every desirable effect. All that was complained of was that the authority of any individual State could not compel vessels to perform quarantine; but if the President gave directions to the officers of the United States at every port to aid the State governments in this respect, every effect would be obtained. The first section of the bill went only to direct the time during which quarantine should be performed, and at what particular place, which would certainly be best determined by the State governments. Indeed, most of them having already fixed on places for the purpose, and erected suitable buildings for the sick, for purifying goods, etc., it would be attended with very great inconvenience if a different place were to be fixed upon by the United States. It was said the right of regulating quarantine did not reside in the State governments; he believed it did, and that the individual States had conceived so was evident from the expense which some of them had been at in erecting buildings, etc, for the purpose. He particularly alluded to the provisions made for this purpose by the State of Pennsylvania, on the Delaware.

Mr. Sitgreaves, of Pennsylvania, would ask his colleague to point out the inconveniences which would arise from passing the law in its present state. It was true that the State of Pennsylvania had made some regulations on the subject of quarantine; but, without the aid of the United States, they could not carry them into effect. They may direct, by their governor and board of health, quarantines to be performed, but they could not enforce any vessels to observe their directions, without the aid of the general government. Some States had, on this subject, no institutions at all; and where they existed it was reasonable to suppose that they would be properly respected by the President in the arrangements he should make under a law like the present. At any rate, no inconvenience need be apprehended from an exercise of a concurrent jurisdiction. If a State should direct one term of quarantine to be performed, and the President another, the longest term, which will comprise both, must be submitted to. But the strongest and best reason for a law such as the one proposed, is that it is matter of very serious doubt whether, upon this subject, the States had any authority at all, and whether all such power is not vested by the Constitution in the Congress, under their general authority to regulate commerce and navigation. He inclined to the last opinion, and believed, upon examination, it would appear to be well founded. On the whole, the provision contemplated might produce good effects, and could not be followed by any evil consequences, and therefore he should vote for it.

Mr. Milledge, of Georgia, spoke in favor of striking out the first section, and of the power of regulating quarantine being in the State governments. Savannah, in Georgia, he said, was one thousand miles from the seat of government, and from their situation in respect to the West Indies, they were very subject to the evil of vessels coming in from thence with diseases; and if they were to wait until information could be given to the President of their wish to have quarantine performed, and an answer received, the greatest ravages might in the mean time take place from pestilential diseases. The State of Georgia had a long law on the subject, and had always been in the habit of regulating quarantine without consulting the general government.

Mr. Bourne, of Rhode Island, spoke again in favor of the bill. It had been objected against the bill that the State might order quarantine to be performed for one length of time and the general government for another. That difficulty would be got over by observing the longest period.

Mr. Giles, of Virginia, said there appeared to him several inconveniences attending the bill. The gentleman last up stated that if a longer time was ordered for quarantine to be performed by either the State or general government, it should be obeyed in preference to the shorter. He believed this would not prove satisfactory. But how did the gentleman propose to get over the difficulty of different places being appointed by the two governments? If, said he, the States had already fixed upon times and places of performing quarantine, he thought it necessary for the general government to interfere in altering them. He thought both time and place should be fixed by the State; but if it were the business of the general government, it was legislative and not executive business. It was said some of the States had no regulations with respect to quarantine; but if they had not, when they found a necessity for them they would have them. It had been said that every useful purpose would be answered by the last clause; why, then, retain the first, against which there are so many strong objections? He hoped it would be struck out.

Mr. Kittera, of Pennsylvania, asked if a State should think it necessary to change the place of performing quarantine, whether the President could always have notice of the change in time, so as to make his regulations accordingly. He believed not. This would be one of the inconveniences which would arise from the first clause. He thought the second would answer every desirable purpose.

Mr. Smith, of Maryland, said that gentlemen who opposed the present bill insisted upon the authority to regulate quarantine being in the State governments. The gentleman from Pennsylvania (Mr. Swanwick) said that each State had its buildings for the purpose. This was not a fact. Some of the States had no regulations on the subject. At Baltimore they had built a hospital four miles from the port, but the State had no authority to stop vessels at it. He asked the gentleman from Georgia (Mr. Milledge) whether there was any power in that State which could stop a vessel of his from going into Savannah though she had sickness on board? He denied that it had. She will sail into port in defiance of their State laws. It was a commercial regulation, and therefore the business of the general government. Mr. S. said he brought in this bill that the regulations respecting quarantine might be authorized by the proper authority. It could not be supposed that the President would alter the places already fixed upon by the individual States without such good reasons as would convince them of its necessity. To suppose the contrary was an unworthy suspicion that the Executive would abuse his power. There were States which had no laws upon the subject. Maryland had a law which had been sanctioned by a law of the general government, and had been renewed this session.

Mr. Williams, of New York, observed that the gentleman last up had said that regulations respecting quarantine were commercial regulations, and therefore vested in the general government. The State of New York had never found any difficulty in causing vessels to stop at a certain place to perform quarantine. Philadelphia and New York had had occasion to make alterations with respect to the proper places of stopping, and they were certainly the best judges as to the propriety of those alterations. It appeared to him that the second clause would answer the purpose wanted. Not that he was by any means jealous of the power of the President, but he believed it would be best for the States to have the power of directing the time and place of performing quarantine, as they could more effectually carry their regulations into effect. The second clause directs that the officers of the general government shall aid State governments, which is all that is necessary.

Mr. W. Lyman, of Massachusetts, thought the individual States had the sole control over the regulations of quarantine. It was by no means a commercial regulation, but a regulation which affected the health of our fellow-citizens. In the town of Boston the small-pox was considered as pestilential disease, and they certainly had a right to make their regulations accordingly. He knew the United States could prohibit the importation of goods but he did not think it was in the power of the United States to prohibit the landing of persons. He believed the bill was unnecessary; that individual States had a right to make such regulations as were necessary for the preservation of the health of their citizens.

Mr. Hillhouse, of Connecticut, said that if gentlemen had been as near infectious disorders as he had been, they would have been convinced of the necessity of making some such regulations as were now proposed. He was not surprised that gentlemen who lived several hundred miles from the shore did not feel anxious about the matter. He thought it was an object which merited the attention of Congress. He knew there were local regulations in many States relative to this subject, which he did not wish to destroy. Gentlemen might as well say that the individual States had the power of prohibiting commerce as of regulating quarantine, because if they had the power to stop a vessel for one month, they might stop it for twelve months. This might interfere with regulations respecting our trade and break our treaties. At the same time, he allowed that the States were the best judges of time and place. Mr. H. proposed two amendments. One was, that the President should make regulations where individual States had not already done it; the second was to make it the duty of officers of the United States to assist the State governments to carry into effect their several laws, until Congress shall make regulations to the contrary.

Mr. Gallatin, of Pennsylvania, said he did not agree in the least with the gentleman from Maryland (Mr. Smith), that the power of regulating quarantine was exclusively in the United States. He conceived the only clause in the Constitution which could at all countenance such an idea was the article relative to commerce; but, he said, the regulation of commerce had nothing to do with commerce. It was a regulation of internal police. It was to preserve the health of a certain place, by preventing the introduction of pestilential diseases, by preventing persons from coming from countries where they were prevalent. Whether such persons came by land or water, whether for commerce or for pleasure, was of no importance—they were all matters of police. The individual States had thought themselves competent to prevent the introduction of slaves coming by sea, although that also might be called a commercial regulation, which they had no right to interfere with. And if a vessel belonging to the gentleman from Maryland was to come to the ports of Baltimore or Philadelphia with a cargo of negroes, he believed that the government of either place would be equal to the preventing of him from landing and disposing of them, though he would say it was an article of commerce. The State governments had also something to do with the internal regulations of their ports. That of Philadelphia was under the direction of wardens and of State laws. He had no objection to the United States assisting the individual States in enforcing their quarantine regulations, but he had an objection to their asserting that they had the sole right of making regulations on that head, or of making health laws for the individual States. He knew that where the legislatures of different States had legislated on the subject they had thought it an important branch of their duty. The words proposed to be introduced by the gentleman from Connecticut—"until Congress shall make regulations to the contrary"—seemed to say that the health laws of the several States were to continue only during the pleasure of Congress, but if the assistance of the United States was only necessary, the amendment of his colleague (Mr. Heister) would answer the purpose.

Mr. Smith, of Maryland, said the gentleman from Pennsylvania (Mr. Gallatin) differed in opinion from him with respect to the States having the power to stop vessels coming into their ports. It was true that the laws of the States of Maryland and Pennsylvania prohibited the importation of slaves, but a vessel might bring any quantity of negroes, provided, on landing, they were not sold. It has been said that the governor of Pennsylvania had stopped vessels from entering this port which were suspected of having diseases on board. That was, he said, before the fort was ceded to the Union. He had not the power now to do it. That such authority had been submitted to was true and proper, but he had no legal right to stop any vessel. The individual States make health laws, but they want the power to carry them into execution; they are good for nothing without such power. That the State of Pennsylvania had passed a health law and carried it into effect was no proof against his assertion. The law which he had now brought forward was meant to give full effect to the State laws. He had no objection to the amendment of the gentleman from Connecticut.

Mr. W. Lyman, of Massachusetts, observed that the gentleman from Maryland did not make the proper distinction. Quarantine was not a commercial regulation; it was a regulation for the preservation of health. If commerce was incidentally affected, it ought so to be, when the object was the preservation of health and life. The United States, it was true, could prevent the importation of any goods, whether infected or not, but it did not thence follow that they could permit the landing of infectious goods contrary to the laws of any State. The several States possessed the sole power over this subject. They were the best judges of the due exercise of it. The right to preserve health and life was inalienable. The bill was not only unnecessary and improper, but it was injudicious interference with the internal police of the States; neither would the amendment which had been offered by the gentleman from Connecticut (Mr. Hillhouse) ameliorate the bill; it would still be interfering with State policy. If that gentleman had any panics about infectious diseases, he might find relief in the laws of the State. If the laws there were not competent thereto at present, the gentleman might remonstrate to their legislature, and no doubt could exist but he would be suitably listened to. As to the argument that States neglected to made regulations, it proved that they supposed them superfluous. Whilst they forbear to do anything, it was proof that nothing ought to be done. The States are the best judges, and have the sole power to determine.

Mr. Kittera, of Pennsylvania, said his objections to the bill would be removed by the amendments of the gentleman from Connecticut. The only point in which they seemed to differ was, whether the President of the United States, or the government of each individual State, was best able to make the wisest regulations. If the first section passed, the President would most probably adopt the regulations of the different States; and by the second, the officers of the United States are commanded to aid in the execution of the State laws.

Mr. Heath was in favor of striking out the first section; he was, in fact, opposed to the whole bill.

Mr. Hillhouse, of Connecticut, said the first clause might be struck out. It was only necessary where no regulation was made. It was said that a regulation of quarantine had nothing to do with trade, but if a State, in order to prevent the introduction of certain goods from a certain country, were to order a quarantine of twelve months to be performed, would it not be destructive of commerce? It certainly would; and if a State had the power of stopping a vessel one month, she can extend it twelve if she pleases.

Mr. Giles, of Virginia, said he did not know which States had legislated on this subject, and which had not. He did not know that any of the States had not legislated upon it; but if they had not done it, they could do it. The gentleman from Maryland (Mr. Smith) had said, to regulate quarantine was a commercial regulation. They were legislating, not upon commerce, but upon preventing the introduction of pestilential disorders. Were these objects of commerce? If a State stops a ship. she does not stop it on account of the goods it contains, but because it contains an infectious disorder which, if it were considered as an article of commerce, certainly ought, at least, to be a contraband article. He did not believe there was any necessity of interference; but, if there was any want of ability to enforce obedience to the laws of the State, he had no objections to furnish it, and that would be done by the proposition of the gentleman from Pennsylvania (Mr. Heister).

Mr. Swanwick, of Pennsylvania, said, if it were to be admitted that the general government were to take upon it the regulation of health, he would ask whether the first section of the present bill contained any regulation of this sort? The State of Pennsylvania, he said, had been at great expense in erecting necessary buildings for the reception of persons and goods infected with diseases. It was to be lamented that gentlemen had not before found out that this was the business of the general government, for it had been a very expensive undertaking to the State of Pennsylvania to provide the necessary buildings for carrying their quarantine and health laws into execution, and they would gladly have turned it over to the United States. He thought the utility of this business remaining in the State government was evident. Commercial regulations were placed in the general government to prevent one State having advantages over another in respect to commerce; but with respect to health, every State was certainly the best judge, and the claim was imperious; and if it were under the power of the general government, and government was to neglect to take the necessary measures, the State would itself take them. During the late sickness at New York it was thought necessary to appoint special committees to aid the State government in this city. The gentleman from Maryland had asked if a State government could stop a vessel from entering any of its ports? If not, they had been infringing on the laws for several years. The governments of New York and Pennsylvania were in the constant habit of preventing ships from entering their ports until they had been examined with respect to their healthiness. Gentlemen had talked about their abode being near or distant from seaports. He could see no use in such observations. It was certainly of first consequence to guard the health of their citizens by every possible means. He said at this port they had laws respecting wardens; there was also in the different States inspection laws, which in some degree affected commerce, but were not the kind of regulations prohibited by the Constitution; these did not interfere with the rights of Congress to regulate commerce. Gentlemen had brought another subject into view, which he could not see any good reason for doing; they had charged gentlemen opposed to this law with being unreasonably jealous of the power of the Executive. Surely, to prevent the landing of diseased persons, or infected goods, could not have any relation to a jealousy of that power. This subject was too often introduced, when, he believed, there was no real occasion for it, though he hoped they never should be wanting in entertaining any justifiable jealousy of the extension of any of the powers of government, if these should be conceived to have been improperly exercised, but he knew of nothing of this kind at present.

Mr. Smith, of South Carolina, said if this question be a mere question of acquiescence in the State laws there might be a propriety in the Federal government overlooking those laws; but it was essentially connected with the powers of Congress on an important subject. He had been surprised to hear gentlemen assert that this subject was not of a commercial nature. The gentleman from Virginia (Mr. Giles), had said diseases were not articles of importation, or if they were, they were contraband; but gentlemen must know that importations of all kinds were under the regulation of Congress, and contrabands as much as any other. Consider how epidemical diseases, imported, affect the United States at large. They do not merely affect the city where first imported, but they obstruct the commerce of all others; they not only embarrassed the commerce, but injured the revenues of the United States. Another point of view in which it had an effect: The laws regulating the collection of imports were counteracted and obstructed by the laws regulating quarantine, and would any gentleman say that a State Legislature had the power to contravene the act of the Federal government to obstruct all the laws by which it collects its revenues? It had been said that this subject could be better considered in each individual State than we could possibly settle it. Who are we? Are we a foreign government? Gentlemen had already forgotten their arguments on former occasions when speaking of the power of the House; they could then do anything and everything; and the people looked up to them alone for protection. If the subject was vested in the general government it was their business to protect the health of their fellow-citizens as much as their property; because, if the performance of quarantine was neglected such neglect naturally tended to affect the lives as well as the revenue and commerce of the citizens throughout the United States. He, therefore, thought it a subject perfectly within the Federal jurisdiction; and as there were States which had no law upon the subject, and as their legislatures had now generally risen, the passing of this law would prevent the necessity of resorting to revolutionary committees of their citizens. Their refusing to legislate upon this occasion would be inviting the people to do the business by committees. The gentleman from Pennsylvania (Mr. Swanwick) had referred to the laws of that State. He thought they had some very exceptionable laws; in particular, their poll-tax on persons coming by water into their State. He thought it would be deviating from the spirit of the Constitution.

Mr. Page, of Virginia, said he should vote for striking out the first section. He should even wish to vote against the bill itself, as it was an attempt to extend the power of the Executive unnecessarily. We might as well undertake to form a system of police force for every city in the Union. The State legislatures could not be interested in opposing the landing of goods any more than Congress, and therefore would not be disposed to do it, except when their health would be endangered by it; but if he were to put in competition the interest of the revenue and the right of the people to preserve their health, which was one of the first rights of nature, he should certainly adhere to the latter at the expense of the former. The master of the vessel who refused to stop at the port of Baltimore, agreeably to the orders of the State government, might have been prosecuted.

at common law. If gentlemen had no other object in view besides the preservation of the health of their citizens, they ought to be satisfied with the second clause, which went to the directing of the officers of the United States to aid the State government in obliging vessels to perform the necessary quarantine. The first clause had only a tendency to extend the prerogative of the President.

Mr. Bourne, of Rhode Island, said gentlemen supposed it to be the duty of the President to coöperate with the individual State governments with respect to the performance of quarantine; but he believed the States would think it an improper interference except he were authorized by law. It was a duty of the President, expressly enjoined by the Constitution, to execute the laws of the Union, but it was not to execute the laws of the State. The gentleman last up had observed that self-preservation required that every State should attend to its own health; but it must be allowed without some check in the United States that the commerce and revenues of the United States were liable to be materially affected by the regulations relative to quarantines; for if the State governments were once allowed to have the power of stopping vessels to perform quarantine, they might prohibit the commerce of any country at pleasure; the vessels from any particular country might be stopped for so long a time, or totally prohibited so as to ruin the commerce with such country on pretense of the vessels containing diseased cattle or other infections. It would be said that this would be an abuse of the power which could not be expected, but if the States had the power they could exercise it as they pleased. If they had the power of regulating quarantine they could not carry it into effect without the aid of the United States, who alone possess the power of regulating navigation and commerce. And he believed that no damages could be recovered (as the gentleman from Virginia supposed) against any master of a vessel who had refused to obey the laws of any State with respect to the performance of quarantine, unless the authority of the United States should interpose by making some legal provision for their being carried into effect so far as they may relate to commerce and navigation.

Mr. Holland, of North Carolina, said that in an inquiry into the subject whether the general government or State legislatures were the best judges of the measures necessary to be taken for the preservation of the health of the several States, it would occur that, the extent of the country being so great, it would be difficult to say what regulation would be best suited to all the ports of the Union, for what would be salutary and proper for one might be improper for another. From this circumstance it would seem that each State should have the power to pass its own laws on this head, and, if so, the first clause should be struck out; to preserve one's health was an article of self-defense. Every individual should take his own measures to preserve his own health, and each State should judge of the best way of doing for its own districts. He had no objection to the calling in of the aid of the general government to the execution of the State law, but not to regulate the time and place of performing quarantine. This was contemplated in the second resolution, and the first was therefore unnecessary. The Constitution being silent in respect to health laws, he supposed the passing of them was left to the States themselves. Those who yet have no laws on this subject will make them when necessary. The question, in his opinion, was by no means a commercial one. The gentleman from Maryland, being a commercial man, may be excused from considering it as one, as he readily converts most things into a commercial view.

Mr. Brent, of Virginia, was in favor of striking out the first clause of the bill under consideration, not from any jealousy of the Executive, but because the Constitution did not authorize such an interference. If the doctrines of the gentlemen from Maryland and South Carolina were true, they would swallow up all of the authority of the State governments. They had suggested that if the State legislatures had the power they might use it so as to injure the general government. He would ask whether this would prove that they did not possess the power? If they possessed the power and exercised it so as to injure the interests of the United States, the Constitution of the Union, he believed, would point out a remedy. The gentleman from South Carolina had said that if the State governments were possessed of this power they might impair the revenue of the United States, and that, therefore, being connected with commerce, the regulating of quarantine must be in the power of the general government. He would ask whether the different States had not the power of regulating the inoculation for the small-pox? Yet this might be so ordered as to affect the trade and commerce of this country, and yet no one would say they had not the power of doing this. If the construction now contended for was carried to its extent, there would be no bounds to it. The States ha always been considered as possessing the power of regulating quarantine. Such was the opinion at the time of adopting the Constitution, and under this impression the States had passed laws on the subject; nor did he believe that necessity, expediency, or policy required that the power should be changed. If this was the case, the question could only be brought forward for the purpose of establishing a constitutional principle, and which he should certainly oppose.

The question for striking out the first section was put and carried, 46 to 23; and the bill was ordered to be engrossed for a third reading.

Friday, May 23, 1796, the bill relative to quarantine was read a third time and passed.

In the Senate, Tuesday, May 24, 1796, Mr. Rutherford, *of New Jersey, from the committee to whom* was referred the bill sent from the House of Representatives, for concurrence, entitled "An act relative to quarantine." reported that the bill be amended by inserting, after the word "that," "until general regulations relative to quarantine are made by law." And on the question to agree to the report it was determined in the negative.

Wednesday, May 25, the bill was read a third time and passed.

Approved May 27, 1796.

(To be continued.)

Medicine in the Early Christian Centuries.—Professor Harnack has recently published an essay, entitled *Medicinische aus der altesten Kirchengeschichte*, or medicine in the earliest church history. It is a part of the eighth volume of von Gebhardt and Harnack's *Texte und Untersuchungen zur Gesichte der Altchristlichen Literatur*, in its fourth fascicle. This essay very thoroughly explores the fields that have been examined casually before; it also gives references that are new to nearly all medico-historical compilations.

Prize Essays on the Action of Alcohol and its Value in Disease.—The American Medical Temperance Association, through the kindness of J. H. Kellogg, M.D., of Battle Creek, Mich., offers the following prizes:

1. One hundred dollars for the best essay "On the Physical Action of Alcohol, based on Original Research and Experiment."
2. One hundred dollars for the best essay "On the Non-Alcoholic Treatment of Disease."

These essays must be sent to the Secretary of the Committee, Dr. Crothers, Hartford, Conn., on or before May 1, 1893. They should be in type writing, with the author's name in a sealed envelope, with motto to distinguish it. The report of the committee will be announced at the annual meeting at Milwaukee, Wis., in June, 1893, and the successful essay read.

These essays will be the property of the Association, and will be published at the discretion of the committee. All essays are to be scientific, and without restrictions as to length, and limited to physicians of this country. Address all inquiries to T. D. Crothers, M.D., Secretary of Committee, Hartford, Conn.

A New Text-Book on Anatomy.—P. Blakiston, Son & Co., announce for early publication a new and systematic text-book on Anatomy, prepared specially to meet the requirements of the students and surgeons of to-day. The retail prices will be from six to eight dollars in cloth and leather bindings.

Prof. J. H. Thompson, Kansas City, reports a case of hæmorrhage after enucleation of an eye—probably the first on record, though likely to occur in any case of hæmophilia.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 1, 1892.

THE IMMIGRANT SHIPS AND OTHER POINTS OF MARINE HYGIENE.

MEDICAL DIRECTOR GIHON addressed the Kings County Medical Society, New York, September 6, his subject being "the hygiene of cholera." We select the following striking paragraph, which will do good if it is circulated widely through the medical press. The quotation is made from a special number of the *Brooklyn Medical Journal*, dated September 10. After reciting some of the dangerous conditions, in the homes of our people, in cholera seasons, DR. GIHON proceeds to show the need of reforms in the matter of immigration. He said:

"Now if houses are foul, what do you think of ships? You probably never have seen a Russian Jew when he starts for this country. He is a man who probably has never washed in his life; he is a man who certainly has worn the rags upon him as many years as these rags would hold together. You put that man in a crowded steerage, he becomes seasick (this same thing applies to the women); he vomits, his dejecta are thrown out in that bunk, it becomes saturated with seasickness, and then he becomes choleraic. Will you tell me what amount of cleansing will put that ship in condition again for a long time, except all such men are taken out and then she is thoroughly washed and cleaned? All these ships are *damp* ships. We are told that water is the very means of communicating cholera. We know in the Navy that water has had a great deal to do with the spread of tubercles. It used to be the disease that prevailed in our service, and the medical officers of the Navy for thirty years were fighting wet decks, and the last few years there has been *no such things as wet decks on board ship*. If the atmosphere can support and transmit this aqueous vapor and with it the tubercle germ, is it not possible that the same atmosphere can transmit that aqueous vapor and with it the cholera germ? I do not know whether DR. STERNBERG will agree with me in that. Certainly I think if that aqueous vapor gets into the mouth in any way, it will be carried down to the stomach. Imperfect sanitation is worse than no sanitation. Fumigation is as unfortunate a word as quarantine. I abominate the word quarantine, because it carries with it the idea of forty days' detention, and that I do not approve of; it would be better to call it sanitary non-intercourse. Fumigation is worse than quarantine, because if you fumigate you burn something and you think you are perfectly safe. A friend told me he was in a house during a fumigation, and as he did not feel inclined to move he stayed there, and sat in the room and read a paper during all the time of the fumigation. There is a report in the papers of a ship which was fumigated, and after it was all over they found an old hen still sitting on her nest; and still another case where a cat was discovered, having gone through the fumigation without being disturbed. Now processes of that sort are worse than none at all, in that they give a feeling of protection when it does not exist."

The lesson from all this graphic delineation seems to be the life-imperiling rapacity of commerce. It is not cholera, in every instance, that the medical watch-dogs of every nation are called upon to repel; nearly every communicable disease in the calendar takes its turn, through maritime channels, in endangering the public health. And it is the recklessness of money-getting, called commerce, that imports to us and to others nearly all these undesirable elements. When one of these immigrant ships lays at anchor and has not yet been "cleared," no one cares to approach it save from the windward. The steerage of some of these vessels is really insusceptible of "cleaning," and yet commerce rebels immediately if the routine operations of fumigation and the like are carried out to the letter. The steamship companies show their defects of management and policy most plainly during times of epidemic, but they are at all times a nuisance; they always stand ready to evade regulations, and to be a law unto themselves, and to cry out against sanitary precautions as being injurious to commercial interests. The influence of medical men may now be exerted in a timely way by showing that the further importation of the dregs and offscourings of Europe and Asia should at once be prohibited by law.

DR. A. N. BELL, editor of the *Sanitarian*, took part in the same discussion concerning cholera, and he took the ground that a board of health is just as necessary to a nation as it is to a city, and that therefore any national efforts against cholera without the support of a National Board are the reverse of useful. He said: "The occurrence of cholera without a National Board of Health of some kind is no exception whatever to a national government without a board of health always doing harm and obstructing the health service. I look upon the action thus far taken as attempting to do that. I have entertained these opinions a long time and I may, I hope, be excused for the emphasis with which I state them, that commerce has been at conflict with the health administration of our Government, with the exception of a few years when we had a Government Board of Health, and it then did something to protect us. National interference, or State interference, or city or municipal interference, without an effective Board of Health, is ineffectual, aggravates and alarms public sentiment and creates undue excitement."

HILL DIARRHŒA.

Hill diarrhœa is a peculiar form of trouble quite common in the hill countries of India, and probably also found in other hilly localities. An interesting account of the disorder is given by SURGEON LIEUT.-COL. CROMBIE in the *Indian Medical Gazette*.

The disease occurs at elevations of 6000 ft. or more above sea level.

"The peculiarities of this diarrhœa are—that in recent cases it is confined to one particular portion of the day, beginning between 3 and 5 o'clock in the morning, and lasting until 11 A.M. During the remainder of the day the patients are well and free to do whatever they like, without fear of any inconvenience from their malady; but the following day, at or about the same time, the diarrhœa recurs and stops again at the same hour. The motions are peculiar, they are liquid and frothy, very light in color, and having the general appearance of whitewash. They are accompanied by much flatulence, but usually without pain. It is a disease of adults; children under twelve years very rarely suffering."

An allied variety of hill trouble is a form of dyspepsia, characterized by gastro-intestinal flatulence. One case reported by CROMBIE, after becoming acclimated to altitude of 6000 ft. went to a place 2000 ft. higher, and had a recurrence of the old trouble.

The monsoons seem to be important factors in the extension of the disease. "As soon as the valleys begin to fill with clouds, and before the rains set in, characteristic cases of diarrhœa begin to apply for help, but it is not until July and August that it becomes epidemic; with the cessation of the rains in September the epidemic cases come to an end."

The disease seems to be independent of the purity or impurity of the water supply, as indeed the almost total exemption of children would alone indicate.

It is very evident that the liver is at fault, but it is quite certain that deficiency of biliary secretion is not the only trouble. CROMBIE is of opinion that the functions of the stomach, pancreas, and intestine are likewise in abeyance, and that the disease is essentially an indigestion.

"Elevation being the principal cause of the disease, all that is necessary for the cure, is a return to a lower level. In early cases this alone is sufficient to put a stop to the whole symptoms within 24 hours."

It is not less curious to note that occasionally, patients so cured can return to the hills without a recurrence of their trouble. Leaving the hills is particularly desirable during the monsoon influences.

For many reasons, many cases can not or do not take advantage of these simple means, and recourse must be had to medicinal treatment. Upon this topic CROMBIE says: "This consists in supplying the deficiency in the secretion of the normal gastric and intestinal ferments, as well as in the administration of intestinal antiseptics to check the abnormal fermentation which the absence of the bile and other secretions permits in the small intestine, and I am more certain of the value of pepsin, ingluvine, etc., in the treatment of the dyspepsia of the hills, than I am of almost any prescription for any disease with which I am acquainted."

The pepsin is best administered as peptonized milk, which in obstinate cases should constitute the sole diet, but in many cases the administration of 10 to 12 grains of pepsin two hours after food is sufficient to relieve all symptoms. Bichloride of mercury is best given 10 or 15 minutes before meals. Even in severe cases this plan of treatment is sufficient to reduce the diarrhœa to one pultaceous stool daily. Unfortunately the treatment fails in some cases, and then resort is had to the mineral acids and euonymin.

Among the more striking cases reported by the author is that of a lady who was troubled for four consecutive rainy seasons, and who one year had the disease all through the cold weather. The next year the disease returned as usual, but after five doses of ingluvine stopped entirely except for one day. Two girls of 14 and 15, were each cured by three 10 gr. doses of pepsin, and a boy of 3 years was cured by a single 5 gr. dose of the same substance.

We are not aware whether anything analogous to this curious complaint exists in the United States.

COMPENSATION AND COMPENSATORY HYPERTROPHY.

A study of the principles of DARWINISM would certainly lead one to expect some compensation for the entire loss or partial removal of any structure. As the presence of each structure depends upon necessity and as the loss of a structure implies absence of function, the demand for that function would require that it be replaced either through changes in similar structures remaining or in entirely diverse tissues. This compensation may be analyzed into these varieties: 1. Sufficient similar tissue still remains in the organism; there simply being increase in functional activity. 2. Numerical increase in the tissue elements remaining. 3. Volumetric increase of the remaining elements. 4. Production of similar tissue in other structures. 5. Assumption of the function by some entirely foreign structure. Of these divisions only the second and third permit of analysis as compensatory hypertrophy the others being purely compensations. It is then apparent that upon partial removal of a structure there may either be a functional or structural change in the remaining portion. That the first is possible may be concluded when the alternating activity between organs that are in pairs is recalled. Rosenstein demonstrated an alternating activity between the two kidneys, proof that there is more secreting structure than is absolutely necessary to fulfill the function. No doubt this is a provision of nature dependent upon the severe strain occasionally placed upon these organs. Again Rosenstein and Hamilton prove that all of the function is assumed by one kidney upon removal of its fellow, and that, although there is volumetric enlargement of the organ, there is no hypertrophy, as the increased size is due to dilatation of the blood vessels and lymphatics.

Upon the other hand pure compensatory hypertrophy has been frequently demonstrated. More especially in regard to the mamma, testicle and muscular fiber. Ponfick shows actual hypertrophy of the liver tissue remaining in dogs after partial removal of that organ. To these must be added the very apparent hypertrophy of blood vessels in collateral circulation and of connective tissue in cases of tenotomy and other operations upon muscles and fasciæ.

Compensation through the formation of new tissue has been recorded several times. Tizzoni asserts that new splenic structures are formed in the omentum of dogs and horses after extirpation of the spleen. Eternod also asserts that splenic tissue appears as a compensatory structure in the Peyer's patches in the intestines of rabbits. Compensation through the agency of other structures is seen in the enlarged heart muscle during valvular disease, and in the secretory relation existing between the skin and kidneys (Laube). Schottin even having found crystallized urea upon the skin in cases of uræmia.

More recently Hassler ("Ueber Compensatorische hypertrophy der Lunge," Virch. Arch., Band 128, Heft 3) proposes to demonstrate compensatory hypertrophy of the lungs. This possibility has already been pointed out by Ratjen, Schuchart, Grawitz and Birch-Hirschfeld. To these is added Meckel's observation of a number of cases in which there was absence of one lung and a marked increase in the size of the remaining organ (J. F. Meckel's Handbuch der Path. Anatomie). The experiments included operations upon twenty-six rabbits and five dogs. One lung was extirpated and the animals killed and examined at various periods from ten weeks to eighteen months after the operation. In only one instance could any hypertrophy be demonstrated. A young dog was examined six months after pneumoneclomy; both sides of the chest were alike and upon opening the cavity it was found that the right lung almost completely filled both sides of the thorax. Microscopical examination was entirely negative. In the other cases the remaining lung remained normal, was not emphyematous and occupied its original position.

The loss of an entire lung is certainly severe enough to demand that some decided reconstructive or functionating change take place. As the examination of the animals disproved anything structural the possibility of a functional change immediately offers itself as a solution. Hassler does not consider the question and makes no observations upon the respirations. But, reasoning from the arguments previously adduced and adding the clinical evidence of functional compensation in cases of pneumothorax, empyema and pneumonia, it is highly probable that in this particular instance the compensation was attained through an increase in the number of respirations. Moreover, this is not adverse to the analysis and the facts easily assume their proper place. A study of compensatory hypertrophy alone is incomplete as it might be expected for each organ and when it cannot be demonstrated the law of demand and supply would seem to be broken.

DISINFECTION BY THE NEW YORK BOARD OF HEALTH.

In the issue of Sept. 17, The Journal censured the disinfecting directions of the New York Board of Health as absolutely inefficient. In reply the board sent a new circular dated Sept. 5, and added the statement, that the circular criticised was published originally years ago and republished without authorization by the N. Y. City Health Department.

The new directions prepared by Dr. H. M. Biggs are above all criticism, and display a thoroughness revealing a practical bacteriologist. The blame for advocating antiquated disinfection methods which do not disinfect, rests hence no longer with the New York Board, but with the paper that published them, without comment, viz., the *N. Y. Med. Record*. Our contemporary evidently recognizes its liability and in its issue of Sept. 24, endorses the comments made by The Journal.

BOOK REVIEWS.

A TREATISE ON HYGIENE AND PUBLIC HEALTH. Edited by THOMAS STEVENSON, M.D., and SHIRLEY F. MURPHY. Vol. I. Philadelphia: P. Blakiston, Son & Co. 1892. Price $7.50.

Never was a book more seasonable than this. The attention of sanitarians and government officials is directed, as never before to the subject of hygienic living and to sanitary conditions, so that there is a grasping for just such books as this. The editor of this work was fortunate in securing the coöperation of the best known writers on the various subjects treated of in the several chapters and sections, so that we have chapters on Air by Prof. J. Lane Notter, of the Army Medical School at Netley. Warming and Ventilation by Prof. W. N. Shaw, of the University of Cambridge; Meteorology. by G. J. Symons. The Influence of Climate on Health, by C. T. Williams; Water, by Thomas Stevenson; The Influence of Soil on Health, by S. M. Copeman; Food, by S. H. C. Martin; Inspection of Meat, by E. W. Hope; Clothing, by Geo. V. Poore; Physical Education, by Frederick Treves; Baths, by W. Hale White; The Dwelling, by P. Gordon Smith and Keith D. Young; Hospital Hygiene, by H. G. House; The Disposal of Refuse, by W. H. Corfield and Louis C. Parkes; Offensive and Noxious Businesses, by Thomas Whiteside Hine; Slaughter Houses, by E. W. Hope.

Every chapter is a text for an important theme, and should have the practical attention of every health board and of every physician. The receipt of Volume II is awaited with much interest.

A HAND-BOOK OF HYGIENE AND SANITARY SCIENCE. By GEORGE WILSON, M.D. Seventh edition. Philadelphia: P. Blakiston, Son & Co. 1892.

This is a fitting companion to the more elaborate work of Dr. Stevenson above noticed. The estimation in which it is held is well attested by the rapid exhaustion of six previous editions, which have as they appeared, received our favorable attention. We find in this issue that the author has been awake to the advances made in our knowledge of bacteriology, and has greatly improved the chapters on Food, Water Supply, Removal of Excreta and House Refuse, Purification of Sewage, Communicable Diseases, Prevention and Disinfection, Sanitary Laws and Official Duties of Health Officers.

A BRIEF BIOGRAPHICAL SKETCH OF THE MEDICAL PROFESSION OF INDIANA COUNTY, PENN. By WM. ANDERSON, M.D., of Indiana, Penn.

This is an interesting little volume, the like of which might be written with profit in very many other localities.

MEDICAL COMMUNICATIONS OF THE MASSACHUSETTS MEDICAL SOCIETY. Vol. 15, No. 3. 1892. Boston: Printed for the Society by David Clapp & Son. 1892.

This volume contains the record of the Society's proceeding in June, 1892, inclusive of an indexing of three years' publications. It is last of the triennial pamphlets which constitute Vol. 15, 840 pages in all.

The scientific work of the year largely pertains to questions of State Medicine and the Public Health. The annual discurse is by the well-known sanitarist, Dr. Frank W. Draper, on the "Medical Profession and the Commonwealth." In this paper we find an unanswerable plea for the divorcement of practical politics from all departments that have to do with health or education.

The Shattuck Lecture this year is by Dr. J. F. A. Adams of Pittsfield, who treats of the "Prevention of Disease in Massachusetts;" this is a brief summary of the practical effects of sanitatation in that State in the last four of five decades. An instructive discussion follows on trichinosis, led by Dr. F. H. Drew, who describes an outbreak of that disease in Coleraine. We find also a paper by Dr. S. W. Abbott, of the State Board of Health, on the desirability of a revision of the classification and nomenclature of disease hitherto employed in the vital statistical tabulations of older American cities and States. "Epidemic Disease, inclusive of Influenza," is the subject of papers by Drs. Henry Jackson, W. E. Fay and P. C. Knapp. "Acute Intestinal Obstruction" was discussed by Drs. Homans, Shattuck, Irish, Warren and Cabot. In the course of Dr. Warren's remarks the following explanation, novel to this writer, of the alleged comparative infrequency of volvulus in this country as compared, for example with Russia: "It is a curious fact, mentioned by Koenig, that this affection is more frequent in some countries, as for instance Russia, where the length of the small intestine, owing perhaps to the peculiar vegetable diet, is said to be much greater than that of men of other nations." The treatment of compound fractures by Drs. Burrill and Dwight is the subject of the most important surgical paper in this volume.

MISCELLANY.

TRI-STATE MEDICAL SOCIETY.—Regular annual session will convene at Kahoka, Mo., Tuesday, October 4, 1892.

1. Uterine Fibroids and their Treatment, J. H. Beucler, M.D., Revere, Mo.
2. Dietetic Treatment of Dyspepsia, J. R. Hollowbush, M.D., Warsaw, Ill.
3. Sanitary Science *vs.* Epidemics, Geo. P. Neal, M.D., Ft. Madison, Ia.
4. Thaumaturgy in Medicine, J. M. Shaffer, M.D., Keokuk, Ia.
5. Intussusception, J. H. Coulter, M.D., Summitville, Ia.
6. A Case of Purulent Pleurisy, H. C. Young, M.D., Bloomfield, Ia.
7. Professional Secrets, W. R. Allison, M.D., Good Hope, Ill.
8. The Physician and his Compensation, O. F. Pile, M.D., Memphis, Mo.
9. Variations of Gestation, T. C. Hays, M.D., Vincennes, Ia.
10. The Hæmatozoan of Malaria, J. Fred. Clarke, M.D., Fairfield, Ia.
11. Operative Treatment of Intra-cranial Lesions, C. E. Ruth, M.D., Muscatine, Ia.
12. Obstetric Reflections, Calvin Snook, M.D., Fairfield, Ia.
13. The Physician as an Educator, W. V. English, M.D., Keokuk, Ia.

MEETING OF INTERNATIONAL MEDICAL CONGRESS (American Public Health Association), in the City of Mexico, November 29th and 30th and December 1st and 2nd, 1892. For the convenience of delegates, and all physicians with their families, who desire to attend this meeting, an elegant Pullman car will leave Chicago November 19th. Short stops will be made at all points of interest between Chicago and the City of Mexico. For further information, maps, time tables, etc., address John E. Ennis, D. P. A., Mo. Pac. Ry., 193 Clark street, Chicago, Ill.

OFFICIAL LIST OF CHANGES in the Medical Corps of the U. S. Navy, for the Week Ending September 24, 1892.

Surgeon H. P. Harvey, detached from the "St. Louis," and granted six months' sick leave.

P. A. Surgeon H. N. T. Harris, detached from Navy Yard, League Island, and to receiving ship "St. Louis"

P. A. Surgeon C. F. Stokes, ordered to Naval Hospital, Yokohama, Japan.

P. A. Surgeon A. C. H. Russell, detached from Naval Hospital, Yokohama, Japan, and ordered to return home.

The Journal of the American Medical Association

VOL. XIX. CHICAGO, OCTOBER 8, 1892. No. 15.

ORIGINAL ARTICLES.

A CASE OF SYRINGOMYELIA.

Read by Title in the Section of Neurology and Medical Jurisprudence, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY WILLIAM C. KRAUSS, M.D.,
OF BUFFALO, N. Y.

Upon the invitation of your Secretary to read a paper before this Section, the thought occurred to me, to report a case of a disease as yet seldom met with in America, although its symptomatology, pathology and diagnosis seem to be well established. To convince one that syringomyelia is more prevalent in Europe than in America, one need but glance at the literature collected by Bloc or that of Buhl, or even that of Baümler, and compare the American with the European references. The cases reported by American authors, as far as I can learn, are those of Starr, Upson, Van Giesen, Booth, Jeffries, Wehlan, Shaw, Church, Hawley.

Whether this disease is actually as uncommon as reports seem to indicate, or whether it has been overlooked and placed in the category of those affections which it so closely resembles, is a question to be solved in the future. To be sure its symptomatology is so intimately allied with progressive muscular atrophy, the first stages of amyotrophic lateral sclerosis, Morvan's disease, anæsthetic leprosy, some forms of hysteria, etc., that a most thorough examination is necessary before it can be detected. On the other hand, whereas all symptoms may point toward syringomyelia, yet cases are on record where the autopsy revealed an altogether different lesion. It is therefore rather a difficult affection to diagnose, and once diagnosed, it is still more difficult to have the diagnosis verified or certified to by the pathologist.

It is not my intention to enter into a careful review of the symptomatology and pathology of syringomyelia, for I trust you are all acquainted with these facts.[1] I only wish to report a case, and the manner in which I arrived at my diagnosis.

Name, D. J. M.; age 30 years; height 5 ft. 7½ in.; weight 140 lbs.; complexion dark; constitution, large, robust, well developed; habits steady, regular, avoiding all excesses.

Antecedents.—His grandparents died of old age. His father died of cancer of the stomach, aged 52. His mother, still living, enjoys good health. He has four brothers and one sister living and likewise healthy.

Early History.—He passed through infancy and adolescence without any serious difficulty save an attack of syphilis which he contracted when 19 years old. Slight secondary symptoms appeared, which under antisyphilitic treatment disappeared without any later manifestations. At school he was bright and intelligent, interested himself in sports, was considered in strength and agility the peer of his comrades. When 20 years old, then living in Chicago, he went on the lakes as wheelman. Shortly thereafter he took to railroading, serving in various capacities as brakeman, fireman, engineer, etc. In 1886, he passed through a severe attack of rheumatism, all joints of the body being implicated. For six months he was unable to do any work. The following year, while working, he received an injury to the index and middle fingers of the right hand. In December, 1888, he was compelled to stay on his engine fifty consecutive hours. Completely exhausted he left for home, and for several days was unable to leave his bed on account of severe headache and dull aching pains along the spine. On resuming work some time afterward, he found that his strength was failing him, his arms would give out quickly, and he noticed that he could touch the hot parts of his engine without experiencing any pain. On several occasions his hands became blistered by coming in contact with the hot iron, and yet he was totally ignorant of when and where the burns were received. Soon thereafter he was compelled to stop work; his arms and hands were wasting rapidly, the muscles of the shoulders were in constant twitching, and his gait was becoming labored and unsteady. In August, 1891, after having consulted several physicians who pronounced his case rheumatism, paralysis, wasting of the muscles, etc., he decided to come to Buffalo for treatment.

Status Præsens.—I noticed nothing striking about his gait or carriage, except that he walked rather cautiously, and tried to favor his right hand as much as possible.

Psyche.—His mind was free and active, he talked intelligently on all subjects under discussion, and appeared to be very hopeful regarding the outcome of his disease.

Motility. Head and Neck.—The muscles are well developed and perform their various functions without any disturbance. The movements of the eyeballs are free, unrestricted, the iris reacts to light and accommodation. The tongue shows no deviation on protrusion.

Arms.—The right arm is perceptibly weakened so that the patient has little use of it. He is barely able to flex the forearm or to extend, pronate or supinate the hand. Flexion and extension of the fingers can be accomplished, but he is unable to pick up small objects or to button his clothes with this hand. The muscles about the shoulder joint are also weakened, and on removing his hat he is obliged to lower the head to the level of his waist. The little motion which he possesses over the shoulder comes from the levator anguli scapulæ and trapezius. The left arm is less affected than the right, although it is far from possessing the normal strength. With this arm he is still able to dress himself and attend to his wants, but he complains of its growing gradually weaker. August 1, 1891, the dynamometer gave right hand 42, left hand 48. Three days later, after the use of electricity, right, 48, left, 50. December 1, 1891, right 35, left 40. March 1, 1892, right 20, left 30.

Atrophy.—The supra- and infraspinati, deltoids, muscles of the arm and forearm are markedly atrophied; the interossei, thenar and hypothenar muscles are wasted to a slight degree. The right arm being the weaker, is naturally more affected than the left. Measurements made Aug. 1, 1891, show the size of the right and left arms respectively.

Left Upper Arm. Circumference.	Distance from Acromion.	Right Upper Arm. Circumference.
9⅛ in.	4½ in.	9½ in.
8⅞ "	7½ "	8½ "
8⅞ "	9½ "	8¼ "
Forearm	External Condyle	Forearm
9¼ in.	3 in.	8⅞ in.
8⅜ "	6 "	7¾ "
6⅞ "	10 "	6⅝ "
Hand, 8½ in.	Tip of median finger, 42 in.	Hand, 8⅛ in.

Circumference of chest, 9 in.; cephalad of the umbilicus, 32½ in.

December 1, 1891, another series of measurements were made:

---

[1] For a thorough study of the symptoms of syringomyelia, I would refer you to Prof. Rump's paper in Neurologisches Centralblatt, 1889, pp. 185, 222 and 257. For a careful, painstaking microscopical examination of the diseased cord, see Van Gieson's paper in the Journal of Nervous and Mental Disease, loc. cit.

Left Upper Arm. Circumference.	Distance from Acromion.	Right Upper Arm. Circumference.
9½ in.	42 in.	9¼ in.
8¾ "	72 "	8⅝ "
8⅜ "	92 "	8⅝ "
Forearm	External Condyle	Forearm
9 in.	3 in.	8¾ in.
7⅞ "	6 "	7⅝ "
6⅝ "	10 "	6¾ "
Hand, 8¼ in.	Tip of middle finger, 42 in.	Hand, 8¼ in.

Circumference of chest, 9 in.; cephalad of the umbilicus, 32½ in.

Another series of measurements was made March 1, 1892, with the following results:

Left Upper Arm. Circumference.	Distance from Acromion.	Right Upper Arm. Circumference.
8⅞ in.	42 in.	8¾ in.
8⅛ "	72 "	8 "
8 "	92 "	7⅞ "
Forearm	From Ext. Condyle	Forearm
8 in.	3 in.	7⅞ in.
6⅞ "	6 "	6¾ "
6 "	10 "	5⅞ "
Hand, 8 in.	Tip of middle finger, 42 in.	Hand, 7⅞ in.

The electrical examinations made December 1, 1891, and March 1, 1892, show no qualitative changes whatever; the cathode closure contraction in every instance was short, sharp and quick. The only change was a quantitative one. The anode, 40 cm., was always placed over the sternum. The cathode employed was Stintzing's normal electrode (3 cm.). The readings were taken from a Hirschmann galvanometer.

Left Side.	Galvanic Current.	Right Side.
2 ma.	Radial nerve	2 ma.
1¾ "	Ulnar "	1½ "
3 "	Median " (elbow)	3⅛ "
2¾ "	" " (wrist)	2¾ "
2¼ "	Deltoid muscle	2¾ "
1 "	Biceps "	2⅜ "
1¼ "	Supinator longus	4 "
2½ "	Flexor corpi radialis	4 "
3 "	Flexor corpi ulnaris	3⅜ "
2¾ "	Flexor pollicis	3 "
3 "	Opponens pollicis	3½ "
3 "	Adductor pollicis	3½ "
3 "	Flexor minimi digiti	3¼ "
3 (?) "	Dorsal interossei	2 "

Left Side.	Faradic Current.	Right Side.
10.5 ma.	Radial nerve	10.6 ma.
10.6 "	Ulnar "	10.5 "
9.8 "	Median " (elbow)	10.5 "
9.5 "	" " (wrist)	9.6 "
9.4 "	Ulnar " "	9.4 "
	Deltoid muscle	
12.3 "	Biceps "	12. "
11.6 "	Supinator longus	10. "
8.8 "	Flexor corpi radialis	8.5 "
10.5 "	Flexor corpi ulnaris	10. "
9.3 "	Flexor pollicis	8.9 "
9.1 "	Opponens pollicis	9.6 "
9.2 "	Adductor pollicis	9.1 "
8.7 "	Flexor minimi digiti	9. "
8.7 "	Dorsal interossei	8.7 "

Through some inadvertence, the deltoid muscles were not examined. The cathode closure contraction in every case was greater than the anode closure contraction.

The examination made March 1, 1892, under exactly similar conditions, showed no particular change. I will only add here the results obtained with the galvanic current.

Left Side.		Right Side.
2¾ ma.	Radial nerve	1¾ ma.
1⅝ "	Ulnar "	1⅞ "
3½ "	Median " (elbow)	2 "
2¼ "	" " (wrist)	1¾ "
2 "	Ulnar " "	1¼ "
3⅛ "	Deltoid muscle	2 "
3½ "	Biceps "	2¼ "
4 "	Supinator longus	4 "
4 "	Flexor corpi radialis	2½ "
3½ "	Flexor corpi ulnaris	3 "
1½ "	Flexor pollicis	2½ "
3 "	Opponens pollicis	2½ "
2½ "	Adductor pollicis	3 "
3¼ "	Flexor minimi digiti	2¾ "
4 "	Dorsal interossei	3½ "

I did not make an electrical examination of the lower extremities, neither did I take any measurements.

Tendon Reflexes.—The biceps and triceps tendon reflexes, likewise those of the extensors and flexors of the hand, were absent. The patellar and Achilles tendon reflexes were markedly exaggerated. Ankle clonus was present on both sides. The superficial reflexes were abolished.

Fibrillation.—Fibrillary contractions were present at intervals, especially of the deltoids. It was almost impossible to make a correct reading of the electrical examination of these muscles on this account. The body and lower extremities presented nothing worthy of attention. The spine was erect, not painful, genital organs well developed, and the muscles of the leg hard and well developed.

Sensibility.—The general or tactile sensibility seemed to be unimpaired. With closed eyes the patient responded promptly whenever the skin was touched, whether by a camel's hair brush or a blunt metallic point. He was also able to distinguish between the two. The muscular sense was undisturbed. On seeing some recent scars upon the hands, I asked the patient whence they came, but he could not say. This led me to make a thorough examination of the thermal and pain senses, and suggested to me the *probable diagnosis of syringomyelia.* The sense of pain and temperature were diminished over certain areas of the body and extremities. Wherever thermo-anæsthesia existed, there also would be found partial or complete analgesia. The only region of the body where this did not hold true was on the back. On the right side, from the lower border of the scapula to the thigh, there existed analgesia with loss of the sense of heat, while on the left side there was analgesia with loss of the sense of cold. The dorsum of the right arm, left hand and left upper arm, central aspect of the thighs, right arm, left hand, upper arm and left half of the body from the umbilicus to the malar bone, presented analgesia and thermo-anæsthesia.

Trophic and Vaso-motor Disturbances.—The hands were cold and cyanosed, the skin roughened, presenting here and there a vesicular eruption. The circulation in the hands was sluggish and injuries healed very slowly, leaving large, prominent scars. The palms were continually moist, and this hyperdrosis seemed to affect the whole body, especially the face. The finger nails were thickened and extremely brittle, the hair covering the hands and arms long and dense.

There were no painful spots along the course of the various nerves—in fact, no subjective symptoms, save a slight numbness about the hands. To judge whether the hands were cold or warm, the patient would carry them to his forehead and judge by the sensation of the contact. The joints of the upper and lower extremities were free, painless and not enlarged. The thoracic and abdominal viscera offered nothing abnormal. The urine was generally acid in reaction, of light specific gravity, and contained neither albumen nor sugar.

Course.—The course of the disease was rapidly progressive. On first seeing him in August, 1891, he was able to use his left hand as he chose and could assist with his right. Gradually he lost strength in both hands, despite the use of massage, electricity, etc., so that in March, 1892, he could scarcely lift them. This story is perhaps best told by the dynamometer. In August, 1891, the right hand measured 42, left 48, while in March, 1892, the right measured 20, the left 30.

The eruption and vaso-motor disturbances of the hands yielded to the galvanic brush, and when I last saw him, his hands were in better condition in this respect than before. The sphincters gradually lost power, although the vesical and anal reflexes seemed to remain intact. The legs, although not appearing to waste, were growing weaker, the gait more spastic, and his general condition poorer, so that in a few weeks he will undoubtedly have to keep his bed. Upon the urgent request of his relatives he returned to his home, and nothing more has been heard from him.

If we can judge a disease by its symptoms, and the symptoms are but the outward manifestations of the disease, then the affection known as syringomyelia must be diagnosed by certain characteristic signs and symptoms. Comparing the symptoms of my patient with those mapped out by authors and investigators on this subject, I have no hesitation in pronouncing the case in question one of syringomyelia. The cardinal symptoms, as muscular atrophy, thermo-anæsthesia and analgesia, and such secondary symptoms as trophic disorders, scoliosis and the spastic-paretic gait, are all present save one, and that scoliosis. Blocq says that curvature of the spine is an almost constant symptom, and the majority of writers have found this to be the case. I see nothing in the pathology of syringomyelia that depends upon or calls forth a spinal deformity, hence do not regard it as a necessary adjunct in the symptomatology. Cases offering all of the cardinal symptoms and some of the secondary can scarcely be denied admission into this select circle—just because it lacks one of the minor points.

The diagnosis of syringomyelia can be made with a tolerable degree of accuracy if the patient can be thoroughly examined, and the differential diagnosis between and analogous clinical features constantly borne in mind. Diseases which have many points in common with syringomyelia are anæsthetic leprosy, Morvan's disease, multiple neuritis, hysteria, muscular atrophy and amyotrophic lateral sclerosis. Morvan's disease and anæsthetic leprosy are of such rare occurrence in America that the differential diagnosis need not be considered. Hysteria and multiple neuritis, as a rule, have very few symptoms which could be construed as syringomyelia; exceptional cases of hysteria might for a time simulate syringomyelia, but by close watching and careful examinations the counterfeit will be readily detected. The two affections which offer to the eye an aggregation of symptoms closely resembling syringomyelia are amyotrophic lateral sclerosis, especially in the early stages, and progressive muscular atrophy. The differential diagnosis of these three affections as I have met them, ignoring for the time the text-book descriptions, may be tabulated as follows:

	Muscular Atrophy.	Amyotrophic Lateral Sclerosis.	Syringomyelia.
Age	25-35	25-35	25-35.
Sex	Male	Male	Male.
Onset	Gradual	Gradual	Gradual.
Course	Progressive	Progressive	Progressive.
Muscular atrophy	Marked	Marked	Marked.
Tactile sensibility	Intact	Intact	Intact.
Sense of pain	Normal	Normal	Analgesia.
Temperature sense	Normal	Normal	Thermoanæsthesia.
Tendon reflexes	Diminished or absent.	Exaggerated	Exaggerated.

The similarity of these affections is striking, and in diagnosing a case of syringomyelia, the verdict will depend upon the stage of the examination, as progressive muscular atrophy, amyotrophic lateral sclerosis or syringomyelia.

A CASE OF TRANSITORY MANIA WITH PECULIAR SEQUELÆ.

Read in the Section of Neurology and Medical Jurisprudence at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY G. R. TROWBRIDGE, A.M., M.D.,
Fellow o' the American Academy of Medicine; Member of the American Medical Association, and N. Y. Medico-Legal Society; 2nd Asst. Physician, State Hospital for the Insane, Danville, Pennsylvania.

The following case was one that proved of especial interest to me, for the reason that I was very much puzzled as to what conditions existed to cause such a sudden and peculiar attack and the consequent train of signs and symptoms. Whether or not my title is a misnomer I do not know, and at all events it is of little importance. I shall give as full and detailed an account of the case as possible for I intend to do nothing more, but leave the comments and diagnosis to others.

Mrs. K., female; aged 47 years; married and has six children. Admitted to this hospital February 17, 1892.

Physically is a short, slight woman, 5 ft. 2 in. in height; weight between 90 and 100 lbs; dark hair and eyes; very nervous temperament. Apparently has no organic disease. The history of the case before admission is as follows: About two weeks before coming to the hospital the patient retired at night feeling as well as usual, and slept quietly until about 3 o'clock in the morning, when she was awakened by a most intense pain in the lumbar region of the spinal column, which extended rapidly upward until it reached the base of the brain and then, as she described it, "it seemed to me as if my head was splitting into a thousand pieces, and that some terrible pressure on the inside was doing it." She had scarcely time to tell her husband to go quickly for a physician, before she sank into a condition of complete unconsciousness. This increased until the woman was in an almost comatose condition; pulse between 35 and 40, respiration slow and shallow; extremities cold and body covered with a profuse, cold perspiration. With proper treatment and care she regained consciousness, and was in fairly good condition physically though greatly prostrated by the attack. In a few days abnormal mental symptoms presented themselves and she developed a number of unsystematized delusions and moreover became almost unmanageable. She conceived the idea that the neighbors in returning from an evening company came to her house bringing mattrasses and bedding with them and slept all night on the floor of her bedroom. She also showed unmistakable homicidal tendencies toward her husband and nurse and moreover endeavored to set fire to the house by upsetting a lamp. Her bodily condition all this time was considerably impaired. Such is the history of the case before her admission to the hospital. She was brought here under the impression that she was going to procure a divorce from her husband, for ill-treatment. On my first examination I found her very weak, and unable to walk or even stand alone, and this inability I ascribed at first to her apparent bodily weakness. Bowels were sluggish; appetite poor; pulse weak and over a hundred. She was rather reticent at first and would talk very little. She was put on tonic treatment and nourishing diet. The bowels were kept free by enemata, as laxative and cathartic remedies were of no avail. This fact first attracted my attention when I learned that there was no evidence of special constipation or accumulation, but there was an utter lack of power to empty the rectum. I afterwards learned that this had been the condition since the night she was taken ill. There was no difficulty in urination. After a residence in the hospital of about five days she became more communicative, and told me considerable about her illness and *that she had been in the hospital five weeks*. She did not, however, mention her delusions. I made up my mind that her inability to walk alone was not due to bodily weakness but to a paralysis of the lower extremities due to some disturbance in the brain or cord. She complained of "cold feet," and yet there was no indication of this being so. The sensation was apparently normal and the patellar reflex was somewhat increased. At this time she showed a cross and irritable disposition, and though in our convalescent ward complained most bitterly of her surroundings, food, clothes, etc., etc., and of being "locked up with a lot of crazy people."

On the morning of March 15, 1892, I found my patient in bed, and she told me she had had another slight attack of the "same pain" she had the night she was first taken ill. She was considerably worried over it, fearing she would be "very ill and this time die." Seeing a good opportunity I asked her to tell me about the attack which she had had at home which she did very accurately, her story corresponding very closely with the history I have given, except she remembered nothing for several days after the attack, and her last remembrance of anything was requesting her husband to go for the doctor. In spite of this statement, however, she remembered her delusions when they were suggested to her, and though her enmity toward her husband had diminished somewhat, she still had the delusion in regard to the neighbors sleeping on the floor of her bed-room, though she did not remember this as developing until sometime after the attack. In other words, though she recovered consciousness soon after her attack, there is a blank of several days which she cannot account for, and yet her condition was one of only an apparent attack of acute mania, as during her excitement she did things which showed she was conscious of her surroundings. She improved considerably both physically and mentally, but at the time of her discharge still clung to her strange delusion regarding her neighbors. Her husband came for her at the time she was discharged and she showed no hostility toward him. I have heard since her discharge that she is improving rapidly as I expected, for at the time she left the hospital she was rapidly gaining the use of her limbs. Such is the case in full as far as I can give it and I shall leave it without diagnosis or comments, but I have regarded it as interesting for the following reasons:

1. The sudden advent of the attack.
2. The comatose condition following it.
3. The peculiar groundless but apparently fixed delusion.
4. The paralysis of the lower extremities and inability to evacuate the bowels.

Was there a lesion? If so, what was it, and where was it?

ADDRESS OF THE CHAIRMAN.—RESPONSIBILITY OF THE NATIONAL AND STATE GOVERNMENTS FOR THE PROTECTION OF THE PURITY OF THE WATER SUPPLIES.

Delivered before the Section of State Medicine at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY BENJAMIN LEE, M.D.,
OF PHILADELPHIA.

Before entering upon the consideration of the question announced as the subject of my address, to which I shall ask your attention for but a few moments, it seems fitting that a brief allusion should be made to the question of the re-organization of the parent asssociation of which this body is one of the members, in the interest of scientific work as contrasted with the transaction of routine business and the reading of essays on abstract subjects. No one who has attended the meetings of the Association with any degree of regularity for the past ten years can have failed to observe the growing importance of the Sections and the hold which they have on the interest of the members. To such an extent is this is true that a writer in the *American Lancet* has not hesitated to formulate the terse phrase "The Sections are the Association." If this be admitted the step is an easy one to the further assertion, "The Sections should control the Association." The chairman of the Section of Ophthalmology at the meeting of the last year devoted his address to indicating in what way the Sections *might* "control the Association," and courteously sent a copy of his address to the chairman of this and, it is presumed, of every other Section, if not to all the members of the Association. At the last meeting of this Section a committee of three was appointed to confer with similar committees to be appointed by the other Sections, to take up the whole subject of the development of the Sections. A place has been given in the program for the report of this committee and an opportunity will then be presented for full discussion of this important movement.

The proposal of the Chairman of the Ophthalmological Section would, as it seems to me, to a great extent do away with the Judicial Council as at present constituted, as also with the Nominating Committee, and place all the business now discharged by those bodies in the hands of a council composed of ex-chairmen of Sections for the three preceding years.

It is claimed that this plan would give the smaller Sections an equal representation in the general administration of the affairs of the Association with the larger Sections, and that the members of such a council would be thoroughly familiar with the needs and interests of the Sections. This would practically put an end to the system of geographical representation which has heretofore been warmly cherished by a large portion of the Association, and which they may feel loath to abandon. While seeing much in the scheme to approve, two objections occur to me which I feel are entitled to consideration. First, the work of the Judicial Council is often large in amount and exacting in character. The ex-chairmen of a Section are apt to be earnest workers in the Section and contributors to its program and discussions. If this labor is assigned to them, is it not possible that it may prove so engrossing as to take them away from the Section sessions, and thus diminish the interest of the latter? Secondly, eight out of the eleven Sections are composed of men who are more or less strictly specialists. Of course it is gratifying and instructive to them to meet those who are following the same lines of work, to become acquainted with them personally, to exchange ideas with them, and profit mutually by one another's experiences, efforts and discoveries. But, if only such as are thus bound together by ties of business interest, and it must be confessed after all that Section work has its business aspect to a very considerable degree, are to meet one another, listen to one another, talk to one another and eat and drink with one another, will not the effect be to increase the narrowness of the professional and intellectual horizon, which their daily routine necessarily involves, instead of broadening the view and widening the field of thought, as one would like to feel to be the result of annual association with the great minds of every branch of the profession. For this latter reason the proposal that each Section should have a stated social gathering of its own should not be too hastily adopted. The idea of having the procedings and papers of each Section reprinted from THE JOURNAL OF THE ASSOCIATION on fine paper with cloth binding would probably entail greater expense on each individual member in a small Section like ours than in a large one. It is, however, well worthy the attention of the members. And just here it may not be out of place to advert briefly to a disadvantage under which our Section labors. Nearly all its members are engaged in the active practice of medicine or surgery. The work which they do here and the time which they bestow, contribute in no way to their knowledge of the particular department of medical science or art to which they devote themselves and on which they depend for a livelihood. They know that in many other Sections papers are being read which would convey to them information of inestimable value, and discussions participated in by men to whom their ears are burning to listen. They are with us, therefore, at no trifling personal self-sacrifice. Hence, it can never be otherwise but that attendance on our sessions should be limited in members and fluctuating in character. Would it not be well to accept this fact and govern ourselves accordingly?

This thought has been in the minds of the officers in arranging the program of the present meeting, certain available periods having had no session assigned them, in order to allow the opportunity for attendance on these of other Sections.

GOVERNMENTAL RESPONSIBILITY FOR THE PROTECTION OF WATER SUPPLIES.

The question of the pollution of streams and other sources of water supply on this continent is rapidly assuming the greatest gravity. It is curious to notice how in this, as in moral and social problems, we are gradually making the discovery that America is after all not very different from the rest of the world, and that measures which have been found necessary in the older civilizations for the maintenance of public peace, the fostering of morality and the preservation of the public health, must also eventually be resorted to by us.

The first lesson which we learned on this question was that of the possibility of the pollution of wells, and a hard lesson it was, and still is, to drive into the head of the farmer or villager, who looks upon his well or spring or pump as a sacred legacy from his ancestors, hallowed by their use for generations, and to doubt the purity of which is to cast a reflection on the character of those who have gone before. The "old oaken bucket," notwithstanding the admirable parody on it by a well known sanitarian, still holds a place in the affections of the people which wins for it the plaudits of an enthusiastic public, wherever the "Old Homestead" is put upon the stage. This idol, however, is rapidly being shattered. Next in order we have been compelled to abandon our faith in the pure mountain stream that comes sparkling and dancing down the hill-sides. Plymouth gave the death blow to this article of belief, but it dies hard. Then the cherished doctrine of the self-purification of streams in the course of a flow of twelve miles was reluctantly abandoned. Finally a careful study of the statistics of our lake cities by Dr. Peter H. Bryce, Secretary of the Provincial Board of Health of Ontario, recently presented before the State Sanitary Convention of Pennsylvania as the Annual Address before the Board, shows conclusively that large bodies of fresh water, however pure by nature, cannot be depended upon to neutralize the germs of disease poured into them by large populations. All of these dis-illusions have in turn aroused public attention to the necessity of warding off the corresponding dangers, and have thus resulted in the formulation of legislative enactments of more or less wisdom and efficiency, generally more wise and efficient as their authors have profited by the experience of foreign countries in their construction.

In other words physical nature like human nature is the same all the world over, and it only requires the presence of the necessary amount of human nature sufficiently condensed to develop invariably certain conditions in physical nature which must be heeded. We are a great people and America is a great country, but even the great American eagle must bow in humility before the universal laws of nature. The problems which are now confronting us in consequence of our rapidly increasing population have forced themselves for many years on the attention of thoughtful minds in England and on the continent of Europe.

It would be then the utmost folly not to avail ourselves of the labor and thought which they have expended upon them. As is well known, the result of such study in Great Britain has led to the establishment of a body known as the "Rivers Conservancy Commission," whose duty is to investigate the reality and extent of this alleged evil of pollution of water supplies and to devise means for its remedy. I feel convinced that such a step is rapidly becoming a necessity in this country. To marshall statistics before this Section in order to convince its members that throughout the entire nation, in villages as well as in cities, thousands of avoidable deaths are taking place every year, in consequence of the pollution of public water-supplies, or that the ratio of comparative purity of water-supplies and comparative rate of mortality is almost a constant one, would, I feel, be a work of supererogation. I take that entirely for granted and do not anticipate the expression of a doubt on the subject. The questions naturally suggest themselves, then, "What are the several State governments doing to protect the purity of public water supplies?" and "To what extent are the State governments capable of preventing the pollution of streams, many of which traverse a large number of States?" This last question is to be considered on its moral as well as physical side. For, while a State government may in the abstract possess the power to prevent the contamination of a stream passing from its territory into that of another State, in the concrete it may find itself quite unable to refute the logic of those who are interested financially in maintaining contamination. I think it will be held to be sound law that no State has a right to pollute or poison a source of water-supply passing into another State any more than an individual has to pollute or poison his neighbor's well. If this be admitted, then, if State governments fail to appreciate their responsibilities in this particular, aggrieved States will have no resource but to petition Congress to enact such legislation as will take the matter out of the hands of the State governments and place it as a question of national hygiene, in those of the national government. In order to furnish data for the commencement of the investigation of this problem, I, some few months since, formulated a brief series of questions addressed to the Secretaries of State Boards of Health as follows:

Sec'y. State Board of Health of

. . . .

Dear Doctor:—Shall I be trespassing too much upon your valuable time, if I request brief replies to the following interrogatories?

1. Has your State any laws prohibiting the pollution of streams or other inland waters?
2. Has your Board adopted any Regulation upon this subject?
3. If either or both, kindly send me copies of the same if procurable.
4. Do any streams enter or traverse your State which have become seriously polluted in other States?
5. Do any streams which have become seriously polluted in your State enter or traverse other States?
6. In your opinion is it wise or politic to attempt to preserve the purity of streams, or should we not rather allow them to be used as sewers and seek our supplies of drinking water from other sources?
7. If you favor the former alternative, do you consider it expedient, in view of the fact that so many of our streams pass from one State into another to petition Congress for the passage of a law forbidding the pollution of streams throughout the entire country, and establishing a "Rivers Conservancy Commission" for the purpose of enforcing such law?

Awaiting a reply to the above inquiries, at your convenience,
Yours very respectfully,
Benjamin Lee,
Secretary State Board of Health of Penn.
1532 Pine St., Jan. 18, 1892.

An analysis of the replies kindly sent by the secretaries of twenty-three Boards gives the following results:

In reply to question No. 1. "Has your State any laws prohibiting the pollution of streams or other inland waters?"

The following named States and provinces possess general legislative enactments for the preservation of the purity of water supplies and streams or other collections of water: Kentucky, Delaware, Wisconsin, New York, Massachusetts, Minnesota, Maryland, West Virginia, New Jersey, Ontario, Quebec, Illinois, California. In all thirteen.

The following named State possesses special legislative enactments for protecting the purity of the water-supplies of certain cities only: Pennsylvania.

In the following named States and provinces the legislatures have made it the duty of the State Board of Health to protect the purity of the water supplies, and conferred upon them powers more or less complete for performing this duty: Delaware, New York, Ontario, Quebec, Minnesota, Massachusets. In all six.

The States of Minnesota and New York are those of the United States which have adopted what appear to me the most stringent and practical laws upon this subject, and time will not be lost in rehearsing their important features. That of Minnesota, founded on the original law of Massachusetts which has since been considerably modified, is as follows:

An act to prevent the Pollution of Rivers and Sources of Water Supply.—Chapter 225, Laws of 1885.

To be enacted by the Legislature of the State of Minnesota.

SECTION 1. No sewage, drainage or refuse or polluting matter of such kind as either by itself or in connection with other matter will corrupt or impair the quality of the water of any spring, well, pond, lake, stream or river for domestic use, or render it injurious to health, and no human or animal excrement shall be placed in or discharged into, or placed or deposited upon the ice of any pond, lake, stream or river, used as a source of water supply by any town, village or city; nor shall any such sewage, drainage, refuse or polluting matter or excrement be placed upon the banks of any such pond, lake, stream or river, within five miles above the point where such supply is taken, or into any feeders or the banks thereof, of any such pond, lake, stream or river.

SECTION 2. The State Board of Health shall have the general supervision of all springs, wells, ponds, lakes, streams or rivers used by any town, village or city as a source of water supply, with reference to their purity, together with the waters feeding the same, and shall examine the same from time to time and inquire what, if any, pollutions exist, and their causes. In case of the violation of any of the provisions of section one (1) of this act, said Board may appoint a time and place for hearing parties to be affected, and shall give due notice thereof, as hereinafter provided, to such parties, and after such hearing, if in its judgment the public health requires it, may order any person or corporation, or municipal corporation to desist from the acts causing such pollutions, or to cleanse or purify the polluting substance, in such a manner and to such a degree as shall be directed by said Board, before being cast or allowed to flow into the waters thereby polluted, or placed or deposited upon the ice or banks of any of the bodies of water in the first section of this act mentioned. Upon the application of the proper officers of any town, village or city, or of not less than legal voters of any such town, village or city, to said Board, alleging the pollution of water supply of any such town, village or city, by the violation of any of the provisions of this act, said Board shall investigate the alleged pollution, and shall appoint a time and place, when and where it will hear and examine the matter, and shall give notice of such hearing and examination to the complainant, and also to the person or corporation, or municipal corporation alleged to have caused such pollution, and such notice shall be served not less than ten (10) days prior to the time so appointed, and shall be served in the same manner that now is, or hereafter may be by law provided for the service of a summons in a civil action in the district court. Said Board, if in its judgment any of the provisions of this act have been violated, shall issue the order or orders already mentioned in this section.

SECTION 3. The district court, or the judge thereof, may, upon the complaint of said Board, or of the proper authorities of any town, city or village, whose sources of water supply shall be so polluted, issue an injunction to enforce the orders of said Board.

SECTION 4. Such orders of the State Board shall be served upon the persons, corporations or municipal corporations found to have violated any of the provisions of this act, and any party aggrieved thereby shall have the *right to appeal* to the district court of the county in which is situated the town, village or city, whose source of water supply is found to have been polluted, and such aggrieved party shall have the right to a trial by jury in the same manner as in a civil action in said court. During the pendency of the appeal, the pollution against which the order has been issued, shall not be continued contrary to the order of the State Board, and upon the violation of the order the appeal shall be forthwith dismissed.

SECTION 5. Any person, corporation or municipal corporation desiring to appeal from any such order of the State Board, shall, within thirty (30) days after the service upon him or it, of a copy of such order, file in the office of the clerk of the district court of the proper county, a notice of *such appeal, together with a bond in the sum of not less than* two thousand (2,000) dollars, with two (2) sureties, to be approved by the judge of said court, conditioned for the prosecution of such appeal to judgment, and for the payment of all the costs and disbursements that may be adjudged against him or it therein, and shall, within three (3) days after such filing, serve a copy of such notice and bond upon the Secretary of the Board; said Secretary shall within ten (10) days thereafter, deliver such copies so served *upon him to the Mayor or other chief executive officer of* any such city, village or town, whose source of water supply has been found to have been so polluted.

SECTION 6. Water boards, water commissioners, water companies and the proper officers of any city, village or town, making use as a source of water supply, of any well, spring, pond, lake, stream, river, reservoir or well, within, or partly within, this State, and distributing the waters thereof for public, domestic and general uses, shall, from time to time, and whenever required by said Board, make returns to said Board, upon blanks to be furnished by it, of such matters as may be required by said Board and called for by such blanks, and any such water board, water commissioners, water company, or officers of any city, village or town, who shall for the space of thirty (30) days after being furnished with such blanks, fail or neglect to make any such report so required, shall for each and every such neglect or failure, forfeit and pay the sum of one hundred (100) dollars, for the use of the local Board of Health, or the proper officers acting as such, of the city, town or village where such delinquent has its principal office. Said State Board shall, in the name of the State, prosecute in the district court of the proper county an action for the recovery of the penalty or forfeit therein imposed.

SECTION 7. This act shall take effect and be in force from and after its passage.

Approved March 7, 1885.

That of New York, while efficacious for the prevention of pollutions of a minor character, is hampered by a restriction in regard to the purification of sewage or alteration of systems of sewerage, which at first sight would seem to largely deprive it of value. It reads as follows:

An act to confer upon the State Board of Health power to protect from contamination, by suitable regulations, the water supplies of the State and their sources. Passed June 13, 1885; chapter 543, Laws of 1885.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

SECTION 1. The State Board of Health is hereby authorized and empowered to make rules and regulations for protecting from contamination any and all public supplies of potable waters and their sources within this State. Provided, however, any such rule or regulation shall not be operative in any county until the county judge of that county shall approve the same.

SECTION 2. The said State Board of Health shall also have power, and it shall be its duty: 1. To publish once a week, for at least six consecutive weeks, all such rules and regulations as it shall have made concerning the contamination of any sub-soil waters, spring, streams, lakes, ponds, reservoirs, or other bodies of water contributing to the potable water supply of any municipality within this State, such publication to be made in one or more newspapers published in the county in which the waters affected by such regulations are located. The cost of publishing the regulations of the State Board of Health, as above provided, shall be paid by the corporation or municipality benefited by the protection of the water supply, concerning which the rules are made. 2. To impose penalties for the violation of, or the non-compliance with, their rules and regulations, not exceeding two hundred dollars in any one case.

SECTION 3. The officer or board having by law the management and control of the potable water supply of any municipality, in all cases where the said municipality derives its water supply in whole or in part from any subsoil water springs, streams, lakes, ponds, reservoirs, or other waters concerning which the State Board of Health shall make any rule or regulation, is hereby authorized and empowered to make such inspection of the sources of said water supply as said officer or board may deem advisable to secure the said water supply from any defilement, and to ascertain whether or not the rules and regulations made by the State Board of Health are complied with.

SECTION 4. In case such inspection shall disclose the violation by any person or persons of any of the rules or regulations of the said State Board of Health relating to the sources of said water supply, the officer or board mentioned in section three of this act shall serve or cause to be served a copy of the said rules and regulations, accompanied by a notice specifying the rule or regulation claimed to have been violated, upon the said person or persons violating such rules or regulations. If the person or persons so served do not immediately comply with the said regulation, the said officer or board having charge of the water supply of the municipality affected thereby shall notify the State Board of Health of the violation of its rules; the State Board of Health shall thereupon examine into the said violation, and if the party complained of is found to have actually violated any of the said regulations, the Secretary of the State Board of Health shall order the local board of health having jurisdiction thereof to convene and enforce obedience to the said regulation.

SECTION 5. In case any local board of health having jurisdiction thereof fails to enforce the order of the Secretary of the State Board of Health within ten days after the receipt of a notification so to do, as provided in the last section, the corporation furnishing the water supply, or the municipality deriving its water supply from the waters for the sanitary protection of which such rules have been made, is hereby authorized and empowered to maintain an action in a court of record and which shall be tried in the county in which the cause of action arose against the person or persons violating the said rules for recovery of the penalty therein provided.

SECTION 6. Every person who shall willfully violate or refuse to obey any rule or regulation made and published by the State Board of Health, and approved pursuant to the provisions of this act, shall be guilty of a misdemeanor, and on a conviction thereof shall be subject to a fine or imprisonment, or both, at the discretion of the court, such fine not to exceed three hundred dollars, nor such imprisonment six months. But the recovery of a penalty in a civil action, as provided in section five of this act and criminal prosecution and conviction under the provisions of this section, shall not be had for the same offense.

SECTION 7. When the State Board of Health shall, for the protection of a water supply from contamination, make regulations, the execution of which will require the providing of some public means of removal or purification of sewage, the **municipality or corporation owning the water-works benefited thereby shall, at its own expense, construct* and maintain such works or means for sewage disposal, as shall be approved by the State Board of Health.

SECTION 8. The State Board of Health, any local board of health, or any municipality or corporation furnishing water, may cause the affidavit of the printer, publisher, or proprietor of any newspaper publishing the rules and regulations as provided by the second section of this act, to be filed with such rules as published in the clerk's office of the county in which the municipality or corporation furnishing the water supply in any case may be situated or located, and such affidavit and rules, or duly certified copies thereof, shall be deemed conclusive evidence of due publication and of all the facts therein stated in all courts and in all proceedings or prosecutions under the provisions of this act.

SECTION 9. All acts or parts of acts inconsistent with the provisions of this act are hereby repealed.

SECTION 10. This act shall take effect immediately.

An act to amend chapter five hundred and forty-three of the laws of eighteen hundred and eighty-five, entitled "An act to confer upon the State board of health power to protect from contamination, by suitable regulations, the water supplies of the State and their sources," relative to the construction of systems of sewerage, and works for the removal and disposal of sewage and the removal of buildings, and giving a right of action for damages.

Approved by the Governor June 2, 1890. Passed, three-fifths being present.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

SECTION 1. Section seven of chapter five hundred and forty-three of the laws of eighteen hundred and eighty-five, entitled "An act to confer upon the State Board of Health, power to protect from contamination, by suitable regulations, the water supplies of the State and their sources," is hereby amended so as to read as follows:

SEC. 7. When the State Board of Health shall for the protection of a water supply from contamination, make regulations, the execution of which will require, or will make necessary, the construction and maintaining of any system of sewerage, or a change thereof, in any or for any village or hamlet, whether the same be incorporated or otherwise, or the execution of which will require the providing of some public means of removal or purification of sewage, the municipality or corporation owning the water works benefited thereby, shall, at its own expense, construct and maintain such system or systems of sewage, or change thereof, and also provide such means of removal and purification of sewage, and also such works or means for sewage disposal as shall be approved by the State Board of Health; and when the execution of any of the said regulations of the said State Board of Health will occasion or require the removal of any building or buildings, the municipality or corporation owning the water-works benefited thereby shall, at its own expense, remove said buildings and pay to the owner thereof all damages occasioned by such removal; and when the execution of any such regulation will injuriously affect any manufacturing or industrial enterprise which is not a public nuisance, the said municipality or corporation shall pay all damages occasioned by the enforcement thereof. And until such construction or change of such system or systems of sewage, and such works or means for sewage disposal, and the removal of any building, is so made by the said municipality or corporation owning the water-works to be benefited thereby, at its own expense, there shall be no action or proceeding taken against any person or corporation for the violation of any regulation of the State Board of Health under this act; and no person or corporation shall be considered to have violated or refused to obey any such rule or regulation. And the owner or owners of any building, the removal of which is occasioned or required or has been removed by any rule or regulation of the State Board of Health made under the provisions of this act, and all persons whose rights of property are injuriously affected by the enforcement of any such rule or regulation, shall have a right of action against the municipality or corporation owning the water-works benefited by the enforcement of such rule or regulation, for all damages occasioned or sustained by such removal and enforcement of the said rule or regulation or either; and an action therefor may be brought against such municipalty or corporation in any court of record in the county in which the premises or property affected is situated, and shall be tried therein.

SEC. 2. This act shall take effect immediately.

In reply to question No. 2. "Has your Board adopted any Regulation upon this subject?" In the following named States the State Board of Health has either by regulation, resolution or executive action attempted to protect the purity of inland waters: Massachusetts, Connecticut, West Virginia, New York, Delaware, Kentucky, Maryland, Wisconsin, Minnesota, Ontario, New Jersey, Illinois, California, Rhode Island, Province of Quebec, Pennsylvania. In all sixteen.

In reply to question No. 6. "Is it wise or politic to attempt to preserve the purity of streams, or should we not rather allow them to be used as sewers and seek our supplies of drinking water from other sources?"

The secretaries of the following named States pronounced unequivocally in favor of making every effort to prevent the pollution of streams and, as far as possible, to keep all impurities from entering them. viz.: Minnesota, Wisconsin, Vermont, Kentucky, Delaware, New York, Province of Ontario, Missouri, North Carolina, Maryland, Province of Quebec. In all eleven.

---

*Italicized by the writer.

The secretaries of the following named Boards doubt the feasibility or possibility of preventing pollution to a very considerable extent, and therefore declare in favor of permitting streams to be used freely and unrestrictedly as sewers, and looking elsewhere for drinking water, viz.: Alabama, Florida, Louisiana, Oklahoma Territory, Rhode Island, South Carolina. In all six.

The secretaries of the following named State Boards considered that the question could not be answered categorically, but that each case of pollution or threatened pollution should be decided upon its merits as it arises: Massachusetts, California, Illinois, Connecticut, Michigan, West Virginia, New Jersey. In all seven.

In reply to question No. 7. "If you favor the former alternative, do you consider it expedient, in view of the fact that so many of our streams pass from one State into another, to petition Congress for the passage of a law forbidding the pollution of streams throughout the entire country, and establishing a Rivers Conservancy Commission for the purpose of enforcing such a law?"

The Secretaries of the following State Boards express themselves as in favor of National legislation forbidding the pollution of streams and establishing a Rivers Conservancy Commission for the purpose of enforcing such legislation: Louisiana, Delaware, Province of Ontario, Missouri, Maryland, South Carolina, Illinois, Connecticut, Michigan, West Virginia, Wisconsin, Vermont, Kentucky, Province of Quebec. In all fourteen.

Dr. N. D. Baker, of West Virginia, says: "I would join in earnestly urging the above action upon Congress."

Dr. F. W. Reilly, of Illinois, says: "The proposition to secure a Rivers Conservancy Commission, with power, authority and means to determine individual cases on the basis of individual conditions has my hearty endorsement."

Dr. C. W. Chancellor, of Maryland, says: "I am decidedly in favor of a 'Rivers Conservancy Commission' with strong laws to prevent pollution of any water-way. The general government will be forced at an early period to enact a law to protect the water supply of Washington City, which is already greatly polluted by the States of West Virginia, Virginia and Maryland. Congress alone can remedy the evil."

Dr. R. C. Atkinson, of Missouri, says: "I heartily approve of such a measure."

Dr. P. H. Bryce, of Toronto, says: "I think the suggestion that the question of the pollution of streams be taken up as a Congressional matter should be approved of and urged by all interested in State or international sanitation."

Mr. E. B. Frazer, of Delaware, says: "I heartily approve of the above. Protect the streams, keep them as the Almighty made them."

The secretaries of the following State Boards are decidedly opposed to invoking the authority of Congress, believing that the separate States are fully capable of dealing with this problem: Rhode Island, Florida, Massachusetts, New Jersey, Minnesota, California.

It will thus be seen that the consensus of opinion of practical sanitarians is strongly in favor of legislative interference for the protection of the purity of water-supplies and streams; that in several States such opinion has crystallized into a public sentiment of such force as to compel the unwilling acquiescence of legislators and lead to the passage of laws for the purpose; that as an ideal question all regard it favorably; but that, as a practical question, the varying conditions of the several States modify the opinions of those residing therein. In some instances the drainage problems of the country are such as to make it appear almost an impossibility to prevent the pollution of streams; in others the manufacturing interests are paramount to all other considerations; and in a third class, the country is so sparsely peopled and there is such an entire absence of manufacturing industries, that the question is not with them an urgent one. Wherever it has forced itself upon the attention of sanitarians, and the difficulties are not so great as to make them appear at first sight insurmountable, but one opinion has been entertained and expressed. This being the case, is it not desirable that this Section should formulate a request to Congress to appoint a committee to consider the expediency of the establishment of a "National Rivers Conservancy Commission," and transmit the same to the Association with a recommendation for its adoption?

In coming to a decision on this really momentous question, it is in the highest degree desirable that we should allow hygienic considerations and the interests of human life alone to have weight! Shall we permit local jealousies or inherited prejudices or questions of political organization to influence us? Are not thinking men who reside in large cities beginning to wake up to the fact that so far as municipal government is concerned we have been grasping at the shadow of liberty only to lose the substance? Shall we allow the bogy of centralization of power to deter us from advocating a measure which may prove the salvation of thousands of lives?

THE NEED OF NATIONAL LEGISLATION FOR THE PROTECTION OF HUMAN LIFE.

Read in the Section of State Medicine, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY A. N. BELL, A.M., M.D.,

OF BROOKLYN, N. Y.,

The need of national legislation for the protection of human life is based upon the knowledge of the transmissibility of epidemic diseases by commerce.

This need obtains to a larger degree for the United States than for any other country in the world, because while the States severally have many inherent rights and obligations of their own, and among those rights certainly that of self-protection against dangers to human life, the nation alone has the power to regulate commerce; and because, related to this commerce, the United States greatly exceeds any other country in the world as the collective centre of all nationalities and habits of life, more or less at variance with the conditions promotive of or in conflict with their own health or of the public health in this country.

Commerce, as hitherto conducted in the United States, in default of national legislation to prohibit the introduction of epidemic diseases has been and is in constant antagonism to the efforts of the States and their seaports to prevent their introduction. Hence, it may be truthfully asserted with regard to sanitary progress in this country, that it has not only been made for the most part without the aid of the general Government, but in actual contention against the Government practice in the contrary direction.

At the outset the general Government essayed to aid the seaports by providing hospitals for those sick with infectious diseases, and warehouses for infected merchandise, both of which commodities it has persistently supplied to the jeopardy of the public health and at great pecuniary cost to the people. It has fallen under my own observation that some such structures eventually became so dangerous that the people in their vicinity destroyed them; but some still exist at other seaports, memorials of the nation's efforts to coördinate the introduction of pestilential diseases with an unrestricted commerce in them. Fortunately, every State in the Union has the power to impose regulations for its own protection; and all—or as many of the States as may so agree—have the power to impose interstate regulations for mutual protection against the introduction and spread of epidemic diseases in their midst. Indeed, not only every State, but every municipality and corporate village or town, has similar power; and it has been in the exercise of such power by the corporate communities and the States severally, that, excepting the progress made in army and naval hygiene, and the work of the National Board of Health during its brief existence, all the progress in preventive medicine in this country has been made by the people in their own behalf against the fostering of disease by commerce. For this reason it is that there are not wanting some advocates of State and local sanitation exclusively as abundantly sufficient. And they would sustain the proposition by reference to the triumphs over preventable diseases by a large number of local boards of health throughout the country, particularly to the progress made under the auspices of the State Boards. Indeed, such advocates—looking at but one side of the question—might cite one of the most triumphant examples of sanitary progress on record to show the sufficiency of local effort alone when fully aroused.

It has been a favorite maxim with me for many years that progress in measures for the protection of human life primarily consists in exposing the consequences of their neglect. In 1864, six years before the first State Board of Health (that of Massachusetts in 1869) was established, I was privileged to belong to a voluntary association of citizens in New York,[1] whose members all appeared to me to be animated by the same sentiment—to seek out and publish the localizing causes of disease throughout the city. The report of the Association at the end of that year showed that, in an estimated population of 700,000, 495,592 persons lived in tenement-houses and cellars, with an average of seven and one-sixth families to each tenement-house, and that many took boarders besides. The tenement-houses of one of the most thickly populated districts contained from 10 to 50 families each. The *pro rata* of ground area to each occupant was less than 15 square feet, and the space in the apartments to each occupant less than 300 cubic feet. One half of the tenement-house population had less than 500 cubic feet of air space to each person. The filthy surroundings were loathsame in the extreme.

The total number of deaths reported for the year 1863 was 25,196—an increase of 3,952 upon the previous year; during the year 1864 there were several hundred more, and for the whole population a fraction less than one death annually to every 35 of the living.

For a period of 25 years, terminating at that time, the number of deaths reported by the City Inspector annually had fluctuated from one death to every 39 to one for every 27, and had even been as high as one to every 22¼ of the whole population; while among the most overcrowded tenement-house population it was one to every 19 of the living.

The outcome of that exposure was the establishment of the Metropolitan Board, in 1866. Under it and its subsequent modifications, cellar tenements have long since ceased to exist; the air space of the tenement-houses has been enlarged, by law, to not less than 600 cubic feet for each occupant; the death-rate of the city has been reduced to an average of about 24.5 per 1000 of the whole population; and for the tenement-house population—counting in the advantage gained by an improved class of tenement-houses—the mortality has been less than among the non-tenement class, due, doubtless, to the better surveillance of the tenement-houses by the Health Department. On the whole, a reduction of about 10 per 1000 of the population annually has been made in New York City since the establishment of the first scientific Board of Health there in 1866. The result since that time, as compared with a like period preceding the awakening of public attention and subsequent legislative action—brought about by the Citizens' Association—has been the saving of more than 500,000 human lives.

Again, the quarantine at the port of New York, aided (?) in the manner before indicated, and fed by commerce, had been, like the tenement-houses of the city, getting more and more deadly—proportional with patronage—until, in 1856, it reached a climacteric period.

The Health Officer's residence was at Tompkinsville, and the boarding place and anchorage in the Narrows, between Staten Island and the Long Island shore. In this narrow channel, from opposite the northern end of Staten Island, extending southward, and including Gravesend Bay, between Coney Island and Fort Hamilton, in the immediate trend of the prevailing southwest wind toward the Long Island shore, not more than 300 yards distant, there were anchored *at one time* during that summer over 200 infected vessels, chiefly with yellow-fever. That the disease should have been communicated to the people in such proximity on the Long Island shore is perfectly consistent with the nature of such a mass of infected material everywhere. Moreover, it was through the midst of this accumulation of infected commerce that all vessels to and from the port of New York, for the time, had to pass.

But it was a blessed epidemic. It roused the people round about to the assertion of their rights, for which they did not cease to contend until the quarantine, as it was at that time conducted, was destroyed, and subsequently, by Act of the Legislature nounced unequivocally in favor of making every effort to prevent the pollution of streams and, as far as possible, to keep all impurities from entering them. viz.: Minnesota, Wisconsin, Vermont, Kentucky, Delaware, New York, Province of Ontario, Missouri, North Carolina, Maryland, Province of Quebec. In all eleven.

---

[1] Citizens' Association.

The secretaries of the following named Boards doubt the feasibility or possibility of preventing pollution to a very considerable extent, and therefore declare in favor of permitting streams to be used freely and unrestrictedly as sewers, and looking elsewhere for drinking water, viz.: Alabama, Florida, Louisiana, Oklahoma Territory, Rhode Island, South Carolina. In all six.

The secretaries of the following named State Boards considered that the question could not be answered categorically, but that each case of pollution or threatened pollution should be decided upon its merits as it arises: Massachusetts, California, Illinois, Connecticut, Michigan, West Virginia, New Jersey. In all seven.

In reply to question No. 7. "If you favor the former alternative, do you consider it expedient, in view of the fact that so many of our streams pass from one State into another, to petition Congress for the passage of a law forbidding the pollution of streams throughout the entire country, and establishing a Rivers Conservancy Commission for the purpose of enforcing such a law?"

The Secretaries of the following State Boards express themselves as in favor of National legislation forbidding the pollution of streams and establishing a Rivers Conservancy Commission for the purpose of enforcing such legislation: Louisiana, Delaware, Province of Ontario, Missouri, Maryland, South Carolina, Illinois, Connecticut, Michigan, West Virginia, Wisconsin, Vermont, Kentucky, Province of Quebec. In all fourteen.

Dr. N. D. Baker, of West Virginia, says: "I would join in earnestly urging the above action upon Congress."

Dr. F. W. Reilly, of Illinois, says: "The proposition to secure a Rivers Conservancy Commission, with power, authority and means to determine individual cases on the basis of individual conditions has my hearty endorsement."

Dr. C. W. Chancellor, of Maryland, says: "I am decidedly in favor of a 'Rivers Conservancy Commission' with strong laws to prevent pollution of any water-way. The general government will be forced at an early period to enact a law to protect the water supply of Washington City, which is already greatly polluted by the States of West Virginia, Virginia and Maryland. Congress alone can remedy the evil."

Dr. R. C. Atkinson, of Missouri, says: "I heartily approve of such a measure."

Dr. P. H. Bryce, of Toronto, says: "I think the suggestion that the question of the pollution of streams be taken up as a Congressional matter should be approved of and urged by all interested in State or international sanitation."

Mr. E. B. Frazer, of Delaware, says: "I heartily approve of the above. Protect the streams, keep them as the Almighty made them."

The secretaries of the following State Boards are decidedly opposed to invoking the authority of Congress, believing that the separate States are fully capable of dealing with this problem: Rhode Island, Florida, Massachusetts, New Jersey, Minnesota, California.

It will thus be seen that the consensus of opinion of practical sanitarians is strongly in favor of legislative interference for the protection of the purity of water-supplies and streams; that in several States such opinion has crystallized into a public sentiment of such force as to compel the unwilling acquiescence of legislators and lead to the passage of laws for the purpose; that as an ideal question all regard it favorably; but that, as a practical question, the varying conditions of the several States modify the opinions of those residing therein. In some instances the drainage problems of the country are such as to make it appear almost an impossibility to prevent the pollution of streams; in others the manufacturing interests are paramount to all other considerations; and in a third class, the country is so sparsely peopled and there is such an entire absence of manufacturing industries, that the question is not with them an urgent one. Wherever it has forced itself upon the attention of sanitarians, and the difficulties are not so great as to make them appear at first sight insurmountable, but one opinion has been entertained and expressed. This being the case, is it not desirable that this Section should formulate a request to Congress to appoint a committee to consider the expediency of the establishment of a "National Rivers Conservancy Commission," and transmit the same to the Association with a recommendation for its adoption?

In coming to a decision on this really momentous question, it is in the highest degree desirable that we should allow hygienic considerations and the interests of human life alone to have weight! Shall we permit local jealousies or inherited prejudices or questions of political organization to influence us? Are not thinking men who reside in large cities beginning to wake up to the fact that so far as municipal government is concerned we have been grasping at the shadow of liberty only to lose the substance? Shall we allow the bogy of centralization of power to deter us from advocating a measure which may prove the salvation of thousands of lives?

THE NEED OF NATIONAL LEGISLATION FOR THE PROTECTION OF HUMAN LIFE.

Read in the Section of State Medicine, at the Forty third Annual Meeting of the American Medical Association, held at Detroit, *Mich.*, June, 1892.

BY A. N. BELL, A.M., M.D.,

OF BROOKLYN, N. Y.,

The need of national legislation for the protection of human life is based upon the knowledge of the transmissibility of epidemic diseases by commerce.

This need obtains to a larger degree for the United States than for any other country in the world, because while the States severally have many inherent rights and obligations of their own, and among those rights certainly that of self-protection against dangers to human life, the nation alone has the power to regulate commerce; and because, related to this commerce, the United States greatly exceeds any other country in the world as the collective centre of all nationalities and habits of life, more or less at variance with the conditions promotive of or in conflict with their own health or of the public health in this country.

Commerce, as hitherto conducted in the United States, in default of national legislation to prohibit the introduction of epidemic diseases has been and is in constant antagonism to the efforts of the States and their seaports to prevent their introduction. Hence, it may be truthfully asserted with regard to sanitary progress in this country, that it has not only been made for the most part without the aid of the general Government, but in actual contention against the Government practice in the contrary direction.

At the outset the general Government essayed to aid the seaports by providing hospitals for those sick with infectious diseases, and warehouses for infected merchandise, both of which commodities it has persistently supplied to the jeopardy of the public health and at great pecuniary cost to the people. It has fallen under my own observation that some such structures eventually became so dangerous that the people in their vicinity destroyed them; but some still exist at other seaports, memorials of the nation's efforts to coördinate the introduction of pestilential diseases with an unrestricted commerce in them. Fortunately, every State in the Union has the power to impose regulations for its own protection; and all—or as many of the States as may so agree—have the power to impose interstate regulations for mutual protection against the introduction and spread of epidemic diseases in their midst. Indeed, not only every State, but every municipality and corporate village or town, has similar power; and it has been in the exercise of such power by the corporate communities and the States severally, that, excepting the progress made in army and naval hygiene, and the work of the National Board of Health during its brief existence, all the progress in preventive medicine in this country has been made by the people in their own behalf against the fostering of disease by commerce. For this reason it is that there are not wanting some advocates of State and local sanitation exclusively as abundantly sufficient. And they would sustain the proposition by reference to the triumphs over preventable diseases by a large number of local boards of health throughout the country, particularly to the progress made under the auspices of the State Boards. Indeed, such advocates—looking at but one side of the question—might cite one of the most triumphant examples of sanitary progress on record to show the sufficiency of local effort alone when fully aroused.

It has been a favorite maxim with me for many years that progress in measures for the protection of human life primarily consists in exposing the consequences of their neglect. In 1864, six years before the first State Board of Health (that of Massachusetts in 1869) was established, I was privileged to belong to a voluntary association of citizens in New York,[1] whose members all appeared to me to be animated by the same sentiment—to seek out and publish the localizing causes of disease throughout the city. The report of the Association at the end of that year showed that, in an estimated population of 700,000, 495,592 persons lived in tenement-houses and cellars, with an average of seven and one-sixth families to each tenement-house, and that many took boarders besides. The tenement-houses of one of the most thickly populated districts contained from 10 to 50 families each. The *pro rata* of ground area to each occupant was less than 15 square feet, and the space in the apartments to each occupant less than 300 cubic feet. One half of the tenement-house population had less than 500 cubic feet of air space to each person. The filthy surroundings were loathsome in the extreme.

The total number of deaths reported for the year 1863 was 25,196—an increase of 3,952 upon the previous year; during the year 1864 there were several hundred more, and for the whole population a fraction less than one death annually to every 35 of the living.

For a period of 25 years, terminating at that time, the number of deaths reported by the City Inspector annually had fluctuated from one death to every 39 to one for every 27, and had even been as high as one to every 22½ of the whole population; while among the most overcrowded tenement-house population it was one to every 19 of the living.

The outcome of that exposure was the establishment of the Metropolitan Board, in 1866. Under it and its subsequent modifications, cellar tenements have long since ceased to exist; the air space of the tenement-houses has been enlarged, by law, to not less than 600 cubic feet for each occupant; the death-rate of the city has been reduced to an average of about 24.5 per 1000 of the whole population; and for the tenement-house population—counting in the advantage gained by an improved class of tenement-houses—the mortality has been less than among the non-tenement class, due, doubtless, to the better surveillance of the tenement-houses by the Health Department. On the whole, a reduction of about 10 per 1000 of the population annually has been made in New York City since the establishment of the first scientific Board of Health there in 1866. The result since that time, as compared with a like period preceding the awakening of public attention and subsequent legislative action—brought about by the Citizens' Association—has been the saving of more than 500,000 human lives.

Again, the quarantine at the port of New York, aided (?) in the manner before indicated, and fed by commerce, had been, like the tenement-houses of the city, getting more and more deadly—proportional with patronage—until, in 1856, it reached a climacteric period.

The Health Officer's residence was at Tompkinsville, and the boarding place and anchorage in the Narrows, between Staten Island and the Long Island shore. In this narrow channel, from opposite the northern end of Staten Island, extending southward, and including Gravesend Bay, between Coney Island and Fort Hamilton, in the immediate trend of the prevailing southwest wind toward the Long Island shore, not more than 300 yards distant, there were anchored *at one time* during that summer over 200 infected vessels, chiefly with yellow-fever. That the disease should have been communicated to the people in such proximity on the Long Island shore is perfectly consistent with the nature of such a mass of infected material everywhere. Moreover, it was through the midst of this accumulation of infected commerce that all vessels to and from the port of New York, for the time, had to pass.

But it was a blessed epidemic. It roused the people round about to the assertion of their rights, for which they did not cease to contend until the quarantine, as it was at that time conducted, was destroyed, and subsequently, by Act of the Legislature supplanted by the most efficient quarantine establishment in the world.

---

[1] Citizens' Association.

It would be an easy matter to cite other scarcely less signal triumphs of sanitation in the United States, independent of the several governments, equal to any that have taken place elsewhere during the now more than forty years since I have been not an wholly inactive observer. It is with knowledge limited to such progress in sanitation by the States and smaller communities that there are not wanting some men of influence wholly opposed to national legislation for the protection of human life. If the States and many populous communities severally have such power and have used it with such good results as those illustrated by the examples cited, they ask, In what consists the necessity for national legislation?

First, because there is too much independent power on the part of State and municipal officials, and, above all, of merchants and their ship masters, to do as they please, regardless of sanitary knowledge, or to ignore its importance when its exercise does not happen to harmonize with the political standard set up, or to chime in with money-getting propensities at the risk of the public health.

Of these, examples are by no means wanting. As one on a small scale, but exceedingly mischievous in its direction, the port of Perth Amboy, N. J., has been a thorn in the side of the New York quarantine and a menace to the health of the city ever since it became a port of entry. It claims the right—though not in so many words—and has frequently made attempts to exercise it (and not always ineffectually, there is reason to believe), to exercise its privilege as a port of entry for infected vessels whose masters desire to shun the New York quarantine, and issuing a new clearance to New York, under the privilege of being a healthful port and a pur-blind health officer to the condition of the vessel.

But dangerous as such powers are, independent of even State control, they are insignificant as compared with some officials in higher places who would sacrifice the health of the State and nation to the opportunity for embarrassing a political opponent.

Every sanitarian in the Union knows that we have not far to seek for a prominent example in justification of these remarks; that for several years preceding the arrival of cholera infected vessels at the port of New York in 1876 the quarantine establishment of New York had been allowed to decay and become notoriously deficient in means for the protection of the public health—in the face of universal intelligence that cholera was aboard—because the Governor of the State preferred to take the risk of a cholera epidemic rather than approve of legislative appropriations for preventive measures to be applied by those who differed with him in politics.

Unfortunately, this is not an isolated case, only in so far as it is the less excusable by reason of the prominence of the official and the consequently increased danger of a following. Indeed, this is already manifest by the action of his immediate successor, who has, for professedly economic reasons, just vetoed an appropriation for completing the repairs which his predecessor was driven to undertake by Mayor Hewitt and others of New York, when the amount asked for by the quarantine commissioners to complete the work would have increased the State tax *per capita* only the sixth of one cent. The functions of the Health Officer of the port of New York, as with that of every other port health officer in the United States, end with each case as it arises, while the recurrence of cases is continuous, a constant tax upon the port and the State, a menace to the public health, and an unmitigated burden to commerce.

Twenty-eight years ago, at the meeting of this Association, at Boston, in 1865, I submitted a brief paper on the Introduction of Disease by Commerce. We have learned a good deal about the etiology of some commercial diseases since that time, but nothing to gainsay the force of the illustration there given, particularly with regard to yellow-fever, which is a constant menace to the southern section of our country, or of the pertinence of other infectious diseases introduced by commerce.

But that paper was evidently premature. And for that reason, fortified as it now is by increased observation and more general knowledge on the subject, an abstract of it is deemed appropriate to this occasion, as follows:

> "Since yellow-fever appeared in the Brazils, about sixteen years ago" (it has now been forty-four), "it has extended over the entire Gulf of Mexico, the West Indies, and to most of the Southern States, and finally to the Pacific Coast. But all the while it has clung with tenacity to regions and localities remarkable for general resemblance—for the time being, at least—in local and climatological conditions.
>
> "In 1851–52 the harbor of Rio Janeiro was crowded with infected vessels, many of them destined for the Pacific. How many of them arrived there still infected, and touched at places where yellow-fever soon after for the first time prevailed, we have no means of knowing. But a few have been traced.
>
> "About the middle of the year 1851 the steamer *New World*, on her way to California, having touched at Callao after having lost almost her whole crew by yellow-fever in Rio. The steamer *Quito* also, during the same season, lost several of her crew there, proceeded to the Pacific, and arrived at Callao in April, 1852. Soon thereafter a mild form of fever broke out in Lima and along the coast of Peru, which the natives called 'pelusa,' just as in 1849 the precursory form of fever which prevailed in Rio was called 'polka.' The disease speedily developed into a perfect type of yellow-fever, and has become domiciled.
>
> "June 6, 1865, the steamer *Ben Franklin* arrived at Norfolk, Va., from St. Thomas, where she had lain several months during the prevalence of yellow-fever, and had lost several of her crew with the disease, and had also lost two or three more with it on the voyage to Norfolk: but at the time of her arrival she had no one on board sick with it. On July 5, a man, who had been working on the boiler of the *Ben Franklin* two days before, was taken with yellow-fever, and died on the fourth day of the disease. This was the starting point of the fever, which subsequently prevailed so extensively at Portsmouth and Norfolk until the beginning of cold weather.
>
> "Early in December, 1857, the U. S. Steamer *Susquehanna* arrived at San Juan de Nicaragua from the Mediterranean two months before, touching by the way at Genoa, Madeira and Key West. She remained at San Juan until the first of the following April, having had during the whole time she laid there a constantly increasing sick list of a precursory fever. At first intermittent, then remittent, but all recovering until March 20, when a case became malignant and died.
>
> "The ship put to sea April 1, and on the 5th arrived off Port Royal, Jamaica, with 106 officers and men down with yellow-fever. Most of these were sent to the hospital, and on the third day afterward the ship sailed for New York, where she arrived April 15, with 51 on the sick list."

The remarkable feature in the case of the *Susquehanna* was that, at San Juan, where the yellow-fever first broke out on board, there was no yellow-fever at that place, and the disease had never been known to occur there. Moreover, the *Susquehanna* had been more than two years on service in the Mediterranean without having had any extraordinary sickness on board when she was ordered to San Juan de Nicaragua; but she had had yellow-fever on board during her preceding cruise in the Gulf Squadron the summer before she was ordered to the Mediterranean, three years before. She was supposed to have been cleansed before she was so ordered; and owing to the unpredisposing conditions of the climate during the interval and while she remained on the Mediterranean station, to the revival of the yellow-fever infection, which, as the sequel shows, she still retained until she returned to the conditions of the yellow-fever habitat at the port of San Juan de Nicaragua.

It is contended by those who persist in their endeavors to elude every restriction upon commerce in disease by foul vessels, that there have been such improvements in ship architecture during recent years as to have well-nigh overcome such conditions as those cited. They would have us believe that because the modern iron ships and water ballast, which have taken the place of wood and stone, are more easily kept clean, they are less liable to infection than the ships of a past generation. But the continued and more certain propagation of epidemic diseases by commerce, and by emigrant ships particularly, is conclusive testimony against that contention. Indeed, admitting the improvements with regard to the passenger-carrying capacity of emigrant ships, such improvements are not infrequently found to be very decidedly in conflict with the health of the passengers, and no less dangerous to ports of arrival than were the passenger and traffic vessels of a past generation.

All sanitarians are more or less familiar with the conditions promotive of disease comprised within the tenement walls of brick vertically and longitudinally divided into compartments by hallways and partitions, pierced here and there with doors for ingress and egress, and provided with windows for light and some fresh air—by shaft or otherwise—from pavement to roof, though ever so much overcrowded. And in civilized communities everywhere the misery of people who, through poverty or other causes, occupy such unhealthful tenements, has never failed to excite public sympathy; insomuch, indeed, that in some communities, in Glasgow, for example, whole blocks of such tenements have been destroyed by national law[2] and healthful tenements substituted, with the result of reducing the death-rate among those who occupied them from 70 to 24 per 1,000.

But not so by any means with regard to the iron tenements afloat, with their several submerged floors and apartments—a basement twenty feet below the water level, with a filthy, stagnant sewer of bilge water beneath it, without a window for light or air nearer than thirty feet above the sewer, and no opening for egress or ingress except through the roof-deck, and this deck not infrequently converted into a pound for cattle. The intervening deck between the cattle pen and the steerage for emigrants is commonly divided into compartments for the mails and storage. The required air space in the steerage by law[3] is from 100 to 120 cubic feet per capita.

Below the steerage is the hold for cargo, dark and airless, except by the ekeage of the foul gases into it from the bilge, which contributes more or less foulness to the cargo according to the tightness or otherwise of the ship's lining between and the nature of cargo.

Surely it is no wonder that such tenements afloat, with no sanitary surveillance worthy of the name, should become the hatcheries of typhus-fever and other infectious and communicable diseases. The *Massilia*, by which typhus-fever was introduced into New York in January last, is an example.

Five years ago, at the meeting of this Association in Chicago, I made a report on "Medical and Sanitary Service on Board Immigrant Passenger Vessels," containing a computation of the death-rate of 27,157 emigrants who took passage to New York during the month of April, 1887. Forty-one died on the voyage—an annual rate of over 55 per 1,000, giving ten days as the average duration of the time the passengers were on board ship. The mortality was not particularly excessive for that month, and it is not believed to be in excess of the present rate.

It is the misfortune of the New York quarantine that no record of the history of infected vessels has been kept; the health officers seem to have regarded their records as personal property, and have taken them away with them. Indeed, in their published official reports even the names of infected vessels are rarely given except incidentally. The report for 1891 is an exception—at least with regard to emigrant ships. But gleaning such records as I have been able to obtain, covering the last five years, there is no difficulty in designating some of the emigrant ships as rounders with regard to their liability to infectious diseases, indicating a continuous state of receptivity. The *Alesia*, which brought cholera to quarantine in 1887, is an example. She brought small-pox twice in 1888, twice in 1890, and she has recently arrived with measles. There are several other repeaters within the same period, of two or three times each. And Dr. William M. Smith, who has occupied the post for nearly twelve years—recently relieved—informs me with regard to yellow-fever particularly, his recollection is that the disease was remarkably persistent year after year to certain vessels during the early years of his service. His report for 1889 contains this remarkable statement:

> The fact is worthy of special consideration, as illustrating the efficiency of the system adopted at this quarantine for an exclusion of yellow fever, that in no instance has the disease occurred among the passengers or crew of vessels from ports known to be infected ports; the cases that have arrived were from localities where the disease was not known to exist, and on vessels that carried clean bills of health.

It would be difficult to adduce clearer evidence than this of the persistence of ship infection and its danger, even when not directly from infected ports.

That such infected conditions of merchant vessels are no less common now than they were thirty years ago, it is only necessary to call attention to the outbreaks of yellow-fever continually occurring on board vessels in frequent communication with Rio, Santos, Guayaquil, and other yellow fever ports, in commercial intercourse with the seaports of the United States.

What is said with regard to the persistence of the yellow-fever infection in such vessels also applies to other infections and the recurring outbreaks of infectious disease on board emigrant ships—*they are not disinfected.*

My opinion, with regard to efficient disinfection and the means of applying it, is sufficiently well-known to require no repetition in this place. It will suffice to state that while *steam* is everywhere acknowledged to be the most efficient of all means, it is still, so far as I am informed, unused for the *disinfection of vessels at our quarantine stations.* At the New York establishment it has been used twice—first to the U. S. transport steamship *Delaware,* infected with yellow-fever in 1862; and second, to the emigrant steamship *Britannia,* infected with cholera in 1887—in both instances in accordance with my advice, and with complete success.

---

[2] English Acts of Parliament, 1866-71.

[3] Acts of Congress, 1882 and 1887.

Moreover, from all I have been able to learn of common practice in the premises, no attempt is made to apply such disinfectants as are used to the bilge—the breeding place of infective germs—and but rarely the hold. The masters of infected emigrant ships have been *directed,* after permission to go to the wharves of the city and removing cargo, to disinfect the hold with sulphur or chlorine, and to wash with mercuric-bichloride solution; but I have not been able to find any one who has *seen* this done—even if it ever has been done. Is there any one who appreciates the by no means overwrought description I have attempted to give of a modern emigrant ship, who thinks that the dark and close recesses and crevices more or less common to all vessels, the special lurking places of disease germs, are ever penetrated by such means; or that the filthy paste composted by the motions of the ship, of the leakage at yellow-fever ports and bilge water with which the limbers of vessels are plastered from the keelson to the deck are ever reached by the bichloride or any other solution, or by any fumes evolved in the hold, without exposing the limbers?

But I am gratified at being able to state that Dr. Wm. T. Jenkins, the recently appointed Health Officer at the port of New York, promises the speedy application of steam to infected vessels, by which means, at a sufficient temperature to kill all disease germs without injury to the vessel, disinfection may be effectually accomplished.

While the recent laws of France and Germany against the importation of American pork obtained, no American ship laden with pork was cleared for those countries. Would it be a greater burden on France or Germany to prohibit the exportation of typhus or any other like dangerous disease thence to the United States than was the prohibition of pork from America? The solution of the question requires no argument, and it applies equally to all other countries.

The port health officers of the United States, and the Health officer of the port of New York in particular, with regard to emigrant ships, are our sole reliance; they are assumed to possess ample power for the prevention of the introduction of epidemic diseases from abroad. But so long as emigrant ships are permitted to receive passengers and their luggage without restriction; vessels known to be infected with cholera, or to have merchandise suspected of cholera infection, refused entry at English ports, but given "clean" bills of health to proceed to American ports; merchant ships to receive any sort of merchandise at the tropical ports of South America and the West Indies where yellow-fever obtains, and clear for American ports without credible bills of health—so long as any of these conditions obtain, and so long as there is no intelligent and reliable sanitary inspection at the *ports of departure,* and for *emigrant ships,* no competent sanitary supervision *during the voyage,* just so long will the people of the United States be subject to epidemics imported from abroad.

Every person acquainted with the construction of sea-going vessels, and with knowledge of the practices of those who command them, knows that it is often wholly impracticable, under the wilful deceptions that commonly obtain among the masters and medical officers of emigrant ships, and the clearance conditions of merchant vessels generally, for health officers to obtain reliable information with regard to infectious diseases at foreign ports; the sanitary condition of the vessels at the time of clearing; their previous condition—whether recently infected or not—or the nature of any diseases that may have occurred during the voyage. Indeed, the present state of conducting commerce in epidemic diseases. by which they are so carefully concealed by those who set more value upon dollars than upon human life, is such that it is frequently altogether impracticable for the port health officer to discover their hiding places.

The only way of meeting and overcoming these dangerous conditions to the health of the people is by efficient *international* regulations, and a necessary prelude to these is a *national health service*—a service such as that contemplated by the bill of Senator Harris for a National Board of Health, introduced in the Senate, December 10, 1891.

As compared with other proposed national legislation with the same object in view:

It provides for a competent *personnel* in the organization of the Board; the utilization of the consular service of the United States as means of information; the Naval and Marine Hospital services; coöperation with State and municipal authorities; voluntary public and private associations—in short, with all sources of information relating to climatic and other conditions affecting the public health. While it makes it unlawful for any merchant ship or vessel from any foreign port to clear for any port of the United States except under clearly defined regulations for the protection of the public health, it respects the right and obligations of foreign nations to practice sanitation at the ports of departure, and—with regard to emigrant ships particularly—during the voyage. It provides against such cases as the one cited—the action of the Health Officer of Perth Amboy against the quarantine regulations of New York. It offers aid to all sanitary authorities in the United States when required, to prevent the introduction, to seek out and destroy epidemic diseases and the conditions which promote them. There is no need of pursuing the excellent provisions of this bill in further detail. I prefer to take it for granted that every member of the Section has made himself familiar with it.

One important deficiency, however, is apparent. While it provides for and exacts practical sanitation by the rightful authorities at ports of departure of foreign nations, it exacts none at our own ports; it leaves the clearance of vessels, emigrant or otherwise, proved to be infected—as was the *Massilia*—at the discretion of those who command them. A clean bill of health can be obtained from the port in such cases in the absence of prevailing epidemic disease in the city, yet the *ship* may be dangerously foul. To fill the Bill, in this particular, the Government is already adequately equipped—it only needs detail. The United States Marine Hospital Service, has, in default of international legislation (contemplated by Senator Harris' bill); done some excellent work through the courtesy of foreign nations—particularly at the port of Havana—to prevent the transmission of epidemic diseases thither. And, apparently, with the purpose of continued reliance upon the service of its medical officers in foreign ports, by courtesy, a bill is now before Congress to that end. But surely it must be well known to all persons conversant with the exclusive rights and practice of foreign nations, that such sanitary service is essentially unstable, ever liable to conflict with the sanitary authorities at ports of departure, and cannot be relied upon to prohibit the departure of an infected ship. The Marine Hospital Service is out of its sphere in this direction, while there is an open field for its labors in another, if the United States would set the example by practicing its own precepts—would see to it that the condition of every *vessel*, before she is permitted to receive cargo, is *clean* in a sanitary sense, and not at the mere voice of her master.

Surely it would be difficult to designate a more inviting field of labor—certainly none more germane to all that pertains to the health of mariners—than this for the Marine Hospital Service.

With such coöperation as this suggestion contemplates, under the auspices of a national board of health as provided for in Senator Harris' bill, and the international sanitary service which it would then be certain to secure, the transmission of epidemic diseases by commerce would speedily cease.

PUBLIC BATHS A PREVENTIVE OF DISEASE.

Read in the Section of State Medicine at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CHARLES H. SHEPARD, M.D.,

OF BROOKLYN, NEW YORK.

A nation is powerful in proportion to the health of its people, and individuals are successful in life largely in proportion to their good health. Man begins existence with a certain stock of vitality, and his success or failure depends upon a careful or prodigal use of that capital, so that good health, which should be his birthright, is of more importance than special fitness for life work.

The losses to the community from disease are beyond estimate, yet these are so common as to blunt our realization of the conditions that surround us. What more desirable therefore, than to seek some measure of relief? It is well to be able to cure disease, but a thousand fold better to prevent it. Herein lies the physician's most noble field of work, that of Preventive Medicine.

Of all forms of prevention or cure, none appeals so directly to common sense as that of baths. None are more simple, and none more powerful when rightly directed. They are inexpensive, and easily put into practice. They act upon the whole surface of the body, and as a rule are agreeable to all: for by quickening the action of the skin a more vigorous action of every internal organ and function is secured.

There are baths of many kinds, the swimming bath, the plunge, shower, douche, warm water baths, medicated baths, mud baths, and the steam or Russian baths; lately the warm water shower bath has deservedly won much favor, but for completeness of adaptation to all classes and conditions of health and disease, no bath that ancient or modern science has yet devised, is equal to the hot air, or as it is more commonly called, the Turkish bath. It is a natural stimulus, and invigorates as nothing else can. It meets all the conditions, either local or general, where any bath is indicated, more fully than any other process.

It has accomplished more as a remedy than any other one agency, and has never been known to injure, when applied by competent hands.

The action of heat, which constitutes the main feature of the Turkish bath, increases the vigor of elimination, and gives full opportunity for the destruction of poisonous ptomaines which are quickly rendered inert or thrown out entirely. The secretions are made more active, and the excretions are increased in volume and efficiency. The increased circulation promotes the discharge of old or used up tissue and the building up of new. The blood is at once a food stream and a sewage stream; for the living body is in solution in the blood, as is also the dead body that has done its work and needs to be eliminated. When it is seen that rheumatism or any other blood disease, which is acknowledged to be of microbic origin, has been quickly relieved by the action of heat, as applied in the Turkish bath, what more logical than to consider that this effect is produced through the destructive action of heat upon the microbes? Furthermore, by purifying and invigorating the circulation, it is reasonable to suppose that the normal germicidal activity of the serum of the blood and other fluids of the body is increased. This throws a hopeful light upon the future treatment of disease. No matter how certainly we may recognize disease, or how quickly we may relieve the pains and penalties of an outraged nature, if we do not thereby learn to avoid the cause, we are pursuing only an *ignis fatuus*, and the lesson of disease is lost.

The modern science of medicine made a great step forward when it came to the knowledge of the disease of the cells, otherwise called cellular pathology. Disease seems to be the result of blood poisoning. Symptoms are but an effort of nature to dislodge this poison, or obtain freedom from it. It is an interesting thought of Dr. Carpenter that cancer is an excretory organ, formed to get rid of poisons in the system. The organic matter given off from the lungs alone, and which is a deadly poison, has been estimated at thirty or forty grains a day for each adult. It is recognized that a drowned man is only a poisoned man, because the waste that is continually going on in every part of the system is of such deadly character as to destroy life in a few moments. When the eliminative functions are in any way interfered with, in so far must the man be poisoned. This is due to the formation and absorption of poisonous substances, and while the specific germ is a cause of disease, the chemical factor is even more important.

In the work of elimination, the depurative process through the skin, is equally, if not more important than that through the bowels and kidneys. Ordinary colds are best explained by the supposition that certain effete matters, which in health are normally excreted by the skin, are retained. This theory is borne out by the effects on the nervous system, and also by the fact that the only successful methods of treatment are essentially eliminative.

To more fully elucidate this subject let us refer to the ancient history of the Turkish bath, as well as the record it has made during the past thirty years or more.

As far back as 500 years before the Christian era, Hippocrates advised the use of baths in general, and the sudorific bath in particular, for the alleviation of disease. In warm climates the practice of plunging into cold water for purposes of enjoyment and invigoration has been wellnigh universal, but the establishment of thermæ, or hot air baths, was looked upon in the first instance as medicinal, though subsequently they were resorted to as a luxury.

Celsus prescribed these baths to his patients. Martial, in a celebrated epigram, recommended the dry heat of the laconium, and also baths in the cold water of Virgin and Martian, two streams in southern Italy famed for their purity. Galen left on record directions for treating marasmus by the use of these baths.

The early Christians, who led a severe and virtuous life, regarded public baths with horror. For many centuries baths and bathing were proscribed. Michelet speaks of the Middle Ages as "a thousand years without a bath." This long period was a time of terrible epidemics. Mysterious plagues, feeding, no doubt, upon the filth of the towns, swept away myriads of people.

Mæcenas, the friend of Augustus Cæsar and of Horace, is said to have been the first who introduced warm baths at Rome, though it is probable that warm bathing was a familiar practice throughout the East long previous to this period. The Hindoos and Mahommedans make cleanliness a part of their religion, and practice what is inculcated. India, Persia and Egypt were early acquainted with the bath. The primary construction was crude, but it was reserved for the Greeks, the greatest architects of ancient times, to erect suitable buildings for public baths.

After the conquest of Greece, about 150 B. C., the Romans soon learned to imitate the example of their predecessors, and in the Augustan age, nearly coeval with the Christian era, Agrippa, the Consul, erected an enormous and splendid bath, of which one small portion, the portico, now called the Pantheon, has descended to our times in a state of excellent preservation. More than a thousand other baths were destroyed by conflagrations and by barbarians, rather than by the hand of time. The ruins of these baths are among the most wonderful monuments of antiquity. Several of them are conspicuous for their extraordinary magnitude, and the magnificence of their decorations. To these baths, consecrated to health and recreation, the Roman citizens resorted as their chief enjoyment on holidays and festivals. The bath was the club house, the café, and the restaurant, and here athletic games of all sorts were played, to give strength and vigor to the Roman people. The news of the day was sought for here, poems were recited, orators spoke from the rostrum, and minstrels sounded their harps.

The price paid for the enjoyment of all this luxury was one quadrans, their smallest coin, much less than one cent, and the Emperors would at times make the baths free, in order to popularize themselves with the people. In Turkey at the present day a large liberality is observed, every one paying according to his means; even the penniless cannot be legally excluded, if he be a Mussulman, as the bath is a religious institution among them, and every individual is required to attend it.

In ancient Rome, at the close of the third century after Christ, there were bathing facilities, including both public and private baths, for 62,800 citizens at any one time.

The earlier generations, those which made Rome the queen of the world, had always considered the bath the most important event and the most essential requirement in their everyday life, though in the course of time, and particularly after the conquest of the East, this was very much changed.

The Romans established precisely similar baths in the countries which they subjugated as they had established in their own, and they adopted a system of sanitary measures well worthy of admiration and imitation.

The occupation of Great Britain by the Romans during the first century of our era, continued for more than three hundred years. Wherever their armies were located, which was in nearly every town, extensive thermæ were built, and among the many then erected there are now to be seen the ruins of more than twenty-five in different sections of England. The most notable of these are in the cities of Bath and Chester. Fine broad roads were built across the kingdom, and thus was kept a line of communication from one station to another. Many ruins indicate the existence of villas, where the Generals and Prefects resided. Attached to the villas were the ever accompanying thermæ, both public and private. Wherever the Romans carried their victorious arms they established their laws, religion and customs.

And where now is the bath? The Romans are gone. The Roman bath is apparently lost. Mr. Urquhart, the father of the modern bath, says: "A people which knows neither Greek nor Latin has preserved this great monument of antiquity on the soil of Europe, and presents to us, who teach our children only Latin and Greek, this institution in all its Roman grandeur and its Grecian taste. The ancient Roman bath lives in its modern offspring, the Turkish hammam."

In our schools are taught the language, literature and laws of the Romans, but one of their most important customs and sanitary measures, and one which very materially served to make them the all-powerful and great people that they were, that of the bath, has been entirely neglected.

It was not till the personal experience of Mr. David Urquhart in the East led him to advocate its extension to the West that the modern movement began. In 1850 he published his book, "The Pillars of Hercules," in which he gave an account of the Turkish and Moorish baths. Six years afterward he became acquainted with Dr. Richard Barter, proprietor of a hydropathic establishent at Blarney, in Ireland. At that place they together constructed the first Turkish bath of modern times.

Gibbon remarks, "Among the innumerable monuments of architecture constructed by the Romans, how many have escaped the notice of history, how few have escaped the ravages of time! The majestic ruins of thermæ, still scattered over all Italy and the provinces, would be sufficient to prove that those countries were once the seat of a powerful and a polite empire. Their greatness and their beauty deserve our attention, but they are rendered more interesting, inasmuch as they were erected at the public expense, and intended for public utility."

The Augustan age was an epoch conspicuous for the development of sanitary measures for the promotion of public health; it was then that a public officer of high dignity was appointed over the management of the baths.

In all the hot air baths of the ancients, as well as in those discovered as having existed in the most primitive form in various parts of the world, however striking the difference may have been as regards construction, the same principle is observed throughout. All are directed to the one great end, that of *sweating*.

In a remedial or therapeutical point of view, the hot air bath claims an attention which is being slowly recognized by the medical profession and the public, and possesses medicinal and sanitary properties far beyond the ordinary bath of warm water. This is based upon its powers of altering the chemical and electrical conditions of the organic structures of the body, and abstracting its fluids.

The work that it has accomplished since its introduction into this country, nearly thirty years ago, has proved beyond question, that there is no more powerful agent for the prevention as well as cure of all filth diseases, fevers, diphtheria, scarlatina, and even small-pox, as well as the almost universal complaints of colds, catarrh, influenza, etc.

The remarkable success of the Turkish bath in the treatment of rheumatism and all blood diseases, preeminently shows the advantage it would be to the community, were large public baths of this kind established throughout the country. With a reform in the dietetic habits of the people, and a frequent and a habitual use of the Turkish bath there is good reason to believe that rheumatism and many other diseases would be far less prevalent. "We ask ourselves," says Erasmus Wilson, "not what disease will be benefited by the thermæ? but *what disease can resist its power?*"

Every hospital, asylum, poor-house, in fact all institutions, and especially those where people are massed together, should not be considered thoroughly equipped without a complete Turkish bath.

Our people are now required to use disinfectants in many cases, but disinfectants come after disease has done its deadly work. Would it not be much more desirable, as a sanitary measure, to require the use of the bath, as a preventive of disease; inasmuch as bathing in its most complete form is the best kind of disinfectant?

We know that many epidemic and contagious diseases would be wiped out of existence by proper sanitary measures enforced in the localities where such have existed, but the culmination of all sanitary measures for the individual would be the Turkish bath.

An incident from a report published some thirty years ago, illustrates the value of the bath in the Island of Cyprus, which contained a mixed population of Mohammedans and Christians. Among the former consumption was not known; among the latter, there was from 12 to 13 per cent. of deaths from that disease.

The great value of this bath has also been thoroughly demonstrated in the treatment of defectives and incorrigibles at the Elmira Reformatory, as appears from a report by the attending physician, Dr. H. D. Wey.

We tax the industrious that we may punish those whom our neglect has made criminals and paupers; we multiply police and public house regulations; and expend large sums in hospitals, but we utterly deride the simple, and comparatively inexpensive appliance of the bath.

The conviction is irresistible that the reason of the universality of its use was because of its utility, that it possessed a healthful and curable potency, which commended it to the practical wisdom of mankind.

American and European visitors to Japan speak with admiration of the public baths of that country, that are not only kept open in summer, but are warmed and open in the winter. In the city of Tokio there are between eight and nine hundred public bathing establishments, each frequented by at least three hundred people, who pay for the privilege an extremely small sum, so small that no one is too poor to afford it. Outside of these baths the Japanese are very much given to bathing in their own houses. They are one of the cleanliest people in the world. Travelers from the Western world frequently express their regret, in describing these Japanese baths, that the progressive peoples of Europe and America have no such establishments.

John Wesley taught that "Cleanliness is indeed next to Godliness." People who are habitually clean are habitually temperate; cleanliness and temperance are twin virtues, and induce self-respect, industry and order. The cost of building and maintaining public baths, which promote cleanliness, temperance, health and morality, would be infinitely less than that of the poor-houses, hospitals, jails, and the legal machinery required therewith. If the masses of our people were given an opportunity of making a selection between the tyranny and self-debasement engendered by the saloon, and the freedom, moral exaltation, and self-respect emanating from the bath, there is little doubt that we would soon have a new order of society.

There is no more doubt of the importance of cleanliness to the person than there is of cleanliness of the streets and houses, in conducing to the well-being, the comfort and the health of the public at large, for if these are only attended to among the masses, there will be proportionally a less chance of the invasion of epidemics, which first begin with the less favored portions of the community and finally sweep all before them. It has frequently been demonstrated that the epidemics which have visited our land, had, for their breeding ground, if not for their origin, the most palpable violations of sanitary laws.

If no higher motive were to influence us, that of self-defence, or prudence, possibly fear, might stimulate us to provide against evils so formidable, which are apparently so effectually and easily guarded against by a frequent use of the Turkish bath. As one of the great sanitary necessities of the day, it is most desirable that large public Turkish baths, as a preventive of disease, should be established throughout the land, at public expense, placed under medical supervision, with admission at nominal rates, so that the poorest individual can partake of their advantages with a feeling of self-respect in paying something for the help and comfort to be derived therefrom. They should be made more attractive than the saloon, and thus prove a more powerful antidote than any law of prohibition.

This will react on the social life of the masses. By purifying the people we would quickly purify their homes.

Heretofore this work has been left to private enterprise, but the time is fast approaching when it should be entertained on a larger scale than any thing yet attempted. The public who are to be the chief beneficiaries, should have the privilege of sharing the expense as well as the direction of such institutions.

The endowment of public baths was among the noblest actions of the Roman Emperors. Eight hundred of those institutions adorned the capital of the Empire, and they supplied, during many eventful years, almost the only medicine to a people distinguished for their corporal and mental vigor.

If prevention be better than cure, then, to found a great public bath would confer a grander blessing than to erect a hospital. To provide an institution which should bring refreshment and vigor to the overworked, healing to the sufferer; warmth, comfort, and self-respect to the victim of squalor, poverty, and neglect, would be to raise a cenotaph more glorious

> "Than ever from Attic or Etruscan hands arose."

THE SANITARY SIDE OF THE DRINK PROBLEM.

Read before the Section of State Medicine, at the Forty-third Annual Meeting of the American Medical Association, at Detroit, Mich., June 7, 1892.

BY T. D. CROTHERS, M.D.,
OF HARTFORD, CONN.

Some conception of this problem may be obtained from the fact that in 1891 over eight hundred thousand persons were arrested in this country charged with being intoxicated and committing petty crimes.

It may be fairly presumed that at least half as many more, using spirits to excess did not come under legal notice. If to this is added opium, chloral, and other drug narcotics—the number reaches enormous proportions.

Practically this vast army of inebriates represents all classes and conditions who are literally withdrawn from the ranks of active workers and producers, and become obstacles and burdens to sanitary life.

They are centers of pauperism and progressive degeneration and the most unsanitary physiological and psychological conditions.

This army literally follows a continuous line of retrogression which antagonizes all evolution, growth and development, and seems to be governed by a uniform law of cause and effect, marked by a beginning development, decline and extinction, the mystery of which makes it the most absorbing scientific problem of the age.

To-day over a million workers are waging a great moral crusade to break up this evil. Politics, religion, education, the pulpit and press are combined in a struggle with this problem, approaching it exclusively from the moral side. Mediæval superstition and moral theories are urged through the pledge, prayer, persecution and punishment to explain and check this evil.

Above all this moral agitation and effort the voice of science appeals to physicians for help. This army of inebriates is increasing, and with it losses and degenerations both of individuals and the race. While inebriates are a part of the great army of the "unfit" that are "mustered out" and crowded out in the race march—there is yet unmistakable evidence that some can be halted, headed off, and returned to health.

Already science has pointed out the possibilities of cure and prevention, that give promise of practically stamping out this evil in the near future.

Some of the outline facts from the sanitary side will show its extent and the possibilities of cure from a larger and more accurate study of the subject. The great sanitary problem of to-day is the knowledge and removal of the causes of disease, and the placing of the victim under the best conditions for a return to health.

To remove the conditions which favor and encourage disease, and break up the breeding places of crime, pauperism and allied forms of degeneration is one of the future certainties of science. There are to-day over a million unrecognized inebriates who are the most defective, dangerous, and degenerate of all classes.

They are centers of pauperism and sanitary evils that pass on into the next generation entailing misery and loss beyond estimate.

The superstition of personal freedom with free will, permits this army of inebriates to go on year after year, destroying themselves, increasing the burden of their families, and building up veritable centers of physical and mental degeneration.

Nothing can be more disastrous from a sanitary and scientific standpoint than the indifference which permits men and women to use alcohol and other drugs, not only destroying themselves but entailing all degrees of degenerations on their descendents.

Sanitary science teaches that no one has a right to destroy himself and peril the health and comforts of others. The moderate and periodic drinkers are always sources of danger to themselves and others. To wait until they become chronic and degenerate into law breakers is to apply the remedy when it is too late.

Public sentiment should not permit one to become an inebriate or tolerate him after he has reached such a stage. He should be prevented and forced to undergo treatment and should be regarded as dangerous to the safety and welfare of the community and isolated until fully restored.

In the near future science will demand that every inebriate have legal guardianship and restriction of personal freedom until he recovers. When these cases realize that such restrictions will be enforced, they will seek treatment in the early stages of their disease. The teaching of science demands that both the pauper and millionaire be seized at the very onset of and forced into conditions of health and sobriety, and saved from becoming burdens on the community, and centers of ruin and misery.

The saloon and the free sale of spirits from a sanitary point is a source of extreme danger. Its influence in any community is bad. It brings sanitary perils by destroying the physical and mental stability of its patrons and both directly and indirectly favors the worst conditions of life. The saloon has no claim for recognition as a business. It is simply a parasite thriving on the decay and degeneration of the community. It is only tolerated by the dense ignorance and selfishness of its defenders. It should be classed with foul sewers, dangerous waters and unsanitary death-dealing forces, etc.

Persecution as a moral evil keeps it alive, but examination from the standpoint of science would be fatal to its perpetuity.

The drink problem would be largely solved could the favoring conditions of saloons be changed.

Unregulated marriage, now a mere matter of accident and impulse is another source of danger perpetuating the drink-curse. Inebriates, insane, and neurotics of all degrees are permitted to propagate and transmit their defects to succeeding generations. The result is a race of neurotics that develop inebriety, and all forms of insanity and idiocy, together with all associated conditions.

The army of neurotics beyond all question reappears in succeeding generations with similar or interchangeable diseases. The inebriates of this generation who marry and raise up children are creating paupers, criminals and insane for the next. They are wrecking their descendents by crippling and incapacitating them to live healthy lives.

Every community illustrates this fact, and the drink problem is more complex and difficult of solution on this account.

We need scientific study and instruction on this point, and a public sentiment that will make marriage a question of sanitary science, then we shall have the means for practical prevention and cure of many present evils.

The drink problem has another sanitary side in defective nutrition—bad ventilation and other conditions of an unhealthy character.

Build up the physique, relieve the condition of starvation—remove the defects of unhealthy living and in many cases the tendency of the drink craze is thwarted.

Mental change—unrest and sudden change involving a strain on the organism to adapt itself to the new conditions for which it is unfit, also overwork, underwork and diseased conditions, defective and retarded growths, and nearly every kind and degree of mental and physical defect enter into the drink problem, and must be recognized and studied.

The present methods of dealing with this problem are followed by startling results.

Of the 800,000 persons who were arrrested last year for inebriety not one per cent. were benefited. Over 99 per cent. were made worse, and confirmed in their habits. The station house and jail are active recruiting places, and the hosts of inebriates who are forced into them are transformed into legions of incurables which never desert or leave the ranks.

Physically the short imprisonment of the inebriate simply removes him from spirits and leaves him less capable of leading a temperate life.

Mentally he has lost a certain self respect and pride of character essential to recovery.

The first legal punishment of inebriates is followed by a species of fatality seen in a constant repetition of the same or allied offenses.

This fact is so apparent that these cases are called "repeaters" in the courts, and the number of sentences to the same person often extends to hundreds.

In one thousand cases confined at Blackwells' Island, New York, 935 had been sentenced for the same offense, drunkenness, from one to 28 times.

The first sentence was a regular switch point from which the victim was precipitated to a constantly descending grade, becoming more and more incapacitated for temperate living.

The system of fines is equally ruinous, because it falls most heavily on the families, making it more difficult to support themselves, thereby increasing the perils of pauperism, both to the victim and those who depend on him for support.

It may be said, and the statement is sustained by many facts, that the legal treatment by the lower courts of cases of inebriety is fully as fatal as the saloons themselves where spirits are sold.

The saloon and police court are literally the school and college for the training and graduation of classes of incurable inebriates that peril every sanitary interest in the country.

The fault is not in the courts and their administration of the law, but in the laws themselves, and in that state of public opinion which urges that all inebriates should be treated as wilful criminals, and arrested and punished as such.

Thus, year after year this terrible farce of prevention of inebriety by fines and short imprisonments goes on and the incurability of the poor victims increases. Crime is increased, pauperism is increased, the most dangerous sanitary conditions are fostered, and the burdens of taxpayers and producers are increased.

The inebriate is always debilitated, and suffers from impaired brain and nerve force—alcohol has broken up all healthy action of the body.

In prison both the quality and quantity of food are ill adapted to restore or build up the weakened organism.

The hygienic influences of jails and prisons are defective in every respect, and adverse to any healthy growth of body or mind.

The psychological influences also are of the worst possible character. The surrounding. and the associates precipitate the victim into conditions of mental despair from which recovery is difficult, if not impossible.

The only compensation to the inebriate is the removal of alcohol, and in this deprivation the State most terribly unfits him and makes him more and more helpless for the future.

Thus, while civilization is one of the sources from which inebriety is produced, the blundering effort to remove it by penal punishment is an actual factor in increasing and intensifying the disorder.

The treatment of inebriety from a scientific standpoint, has passed the stage of experiment and is supported by a great variety of experience and collateral evidence that cannot be disputed.

Probably the largest class of inebriates in this country are without means of support and may be termed the indigent and pauper class.

This class, non-supporting and burdensome, should come under legal recognition and be committed to workhouse hospitals, built for this purpose, preferably in the country, upon large farms and amid the most favorable environment.

These hospitals should be training schools in which medical care, occupation, physical and mental training could be applied for years, or until the inmates had so far recovered as to be able to become good citizens.

Such hospitals should support themselves in part from the labor of their inmates, having been built from monies received from a tax imposed on liquor dealers, or a license fund, and be independent of the tax payer or of State support.

These places would receive the classes who now are sent to jail, and that other class who are neglected until they have passed into the chronic stage and have become inmates of prisons and insane asylums.

A very large proportion of these several classes could be made self-supporting while under treatment, and in many cases be an actual source of revenue. The hospitals would naturally be divided into two classes. The first would receive the better, or less chronic cases; the second would have the incurables, and those whose recovery was deemed more or less doubtful. In one case the surroundings and discipline would be more adapted for the special inmates than in the other, but the same general restraint would be followed in each.

In both recoveries would follow. A large class would be restored to society and become producers. In the second, cases would be housed and made to take care of themselves, which would be an immense gain to society in economy and safety.

Private enterprise should be encouraged by legislation to provide smaller hospitals for the better class and those who would be unwilling, or whom it would be undesirable to compel to enter public asylums. Here the commitments should be both forced and voluntary, and the restraint combined with the fullest and latest appliances of science for the end to be accomplished, blending seclusion and good surroundings to build up and make recovery possible.

The first step is to recognize the fact that the inebriate, whether continuous or periodic, has to a greater or less degree, forfeited his personal liberty, become a public nuisance and an obstacle to social progress and civilization. Second, that he is suffering from a disease which affects society and every member of the community in which he lives, and from which he cannot recover without aid from other sources, making it absolutely necessary that he should be forced into quarantine on the same principle as the small pox or yellow fever patient. This is simply carrying out the primitive law of self-preservation. Naturally, the money to accomplish this shall come from the license revenue, on the principle that every business should provide for the accidents and injuries which follow from it. Railroad companies and other corporations are required to pay damages for the accidents which follow their business, and this is conceded to be justice. But to-day the tax on the liquor traffic is used to support courts and jails where the inebriate, by fines and imprisonment, is only made worse or more incurable. Thus, literally, the business of selling spirits is increased by the almost barbaric efforts of courts and jails, and every person so punished is made a permanent patron of that business. Against this all the teachings of science and all practical study utter loud protest.

The practical success of workhouse hospitals for inebriates is demonstrated in every self-supporting jail and State's prison in the country where the obstacles are greater and the possibilities of accomplishing this end more remote. This can also be seen in asylums for both insane and inebriates, in the various sanitaria and hospitals through the country where the capacity for self-support and the curability of these cases are established facts.

More than that, these hospitals would relieve society of great burdens, of loss and suffering, the diminution of the number of the inebriates indeed become a practical certainty, the extent of which we can have no conception of at present.

It is impossible at the present time to estimate the beneficial results that would follow a systematized plan of thus housing and treating the inebriate, but there are positive indications that its effect would be felt in all circles. One of the great fountain heads of insanity, criminality and pauperism would be closed, and a new era would dawn in the evolution of science.

HINTS UPON THE PATHOLOGY OF SO-CALLED FRIEDREICH'S DISEASE, BASED UPON THE STUDY OF A SERIES OF TWENTY-THREE CASES.

Read in the Section of Neurology and Medical Jurisprudence, at the Forty third annual meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

BY SANGER BROWN, M.D.,
OF CHICAGO.

Of the utmost importance in the present condition of the subject is any addition to the stock of exact clinical and pathological data in the study of degenerative diseases of the central nervous system, for it is only by the examination of such data that a durable and reliable basis of classification can be reached for the guidance of the practitioner.

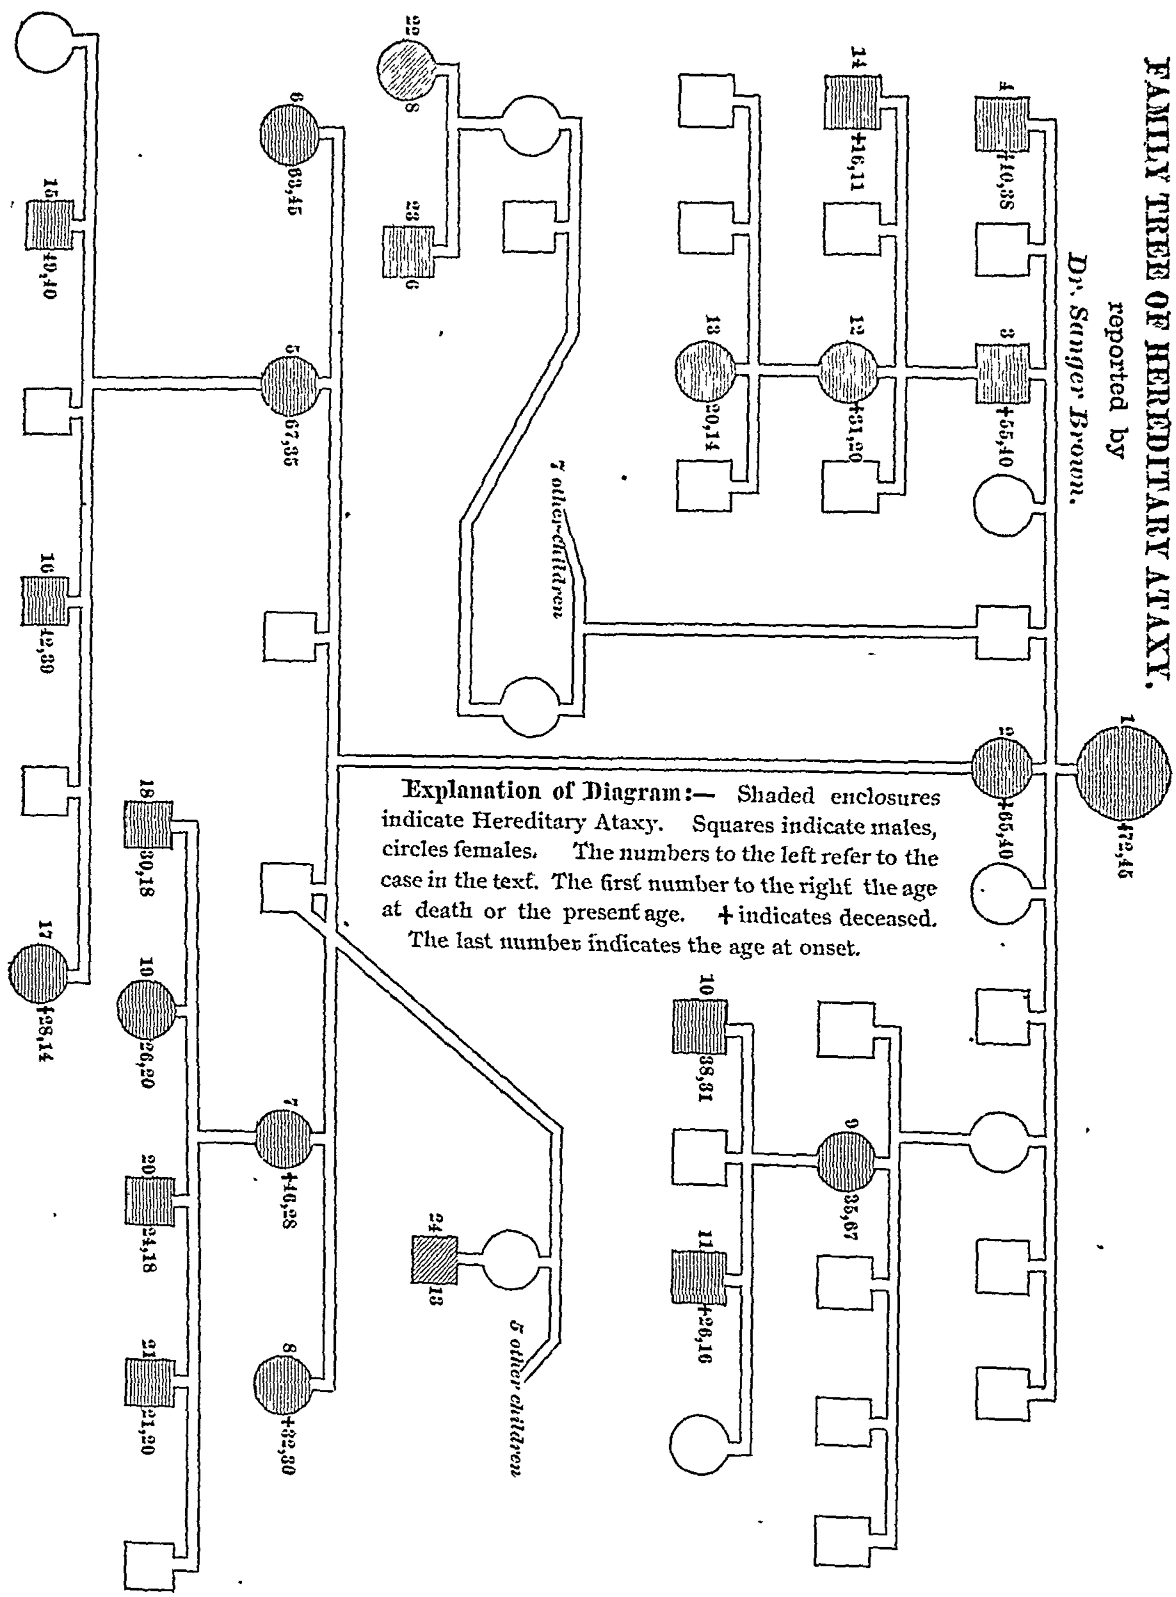
There has been such a large accumulation of recorded facts bearing upon the subject within the past few years, that the conclusions previously reached from the data then at hand, are no longer tenable.

Two broad divisions, however, may so far be safely made, one in which heredity can be demonstrated to play a prominent part, and one in which this influence is not apparent. Of the former, the so-called Friedreich's disease may be taken as a type, and of the latter the ordinary form of tabes, and unless it should be demonstrated that heredity plays an important part in the progressive form of spinal muscular atrophy, and disseminated sclerosis, the pathological process giving rise to the symptom complex, commonly described as Friedreich's disease, must, I think, at the present time, be regarded as constituting the sole instance of hereditary degenerative disease of the central nervous system. In this disease the essential pathological features are, that certain tissues have derived such a deficient vital endowment from the parent, that they undergo a more or less premature, rapid and extensive degeneration, and further, the effect of this process is mainly, if not exclusively, confined to the so-called upper nerve segment, and to the conducting filamentary process, and not the body of the cell of this segment; different cases and series of cases presenting considerable variation both in the extent, degree and period of onset of the pathological process.

That in the future there may be discovered certain laws determining the significance of certain variations, such, for instance, as whether or not the knee jerk is lost, retained or exaggerated, or whether or not there is nystagmus, optic nerve atrophy or integrity of the sphincter, is quite possible; but existing data do not, I think, render an attempt to found a classification upon these differences at present feasible.

With this view of the subject, the symptom complex marked out by Friedreich in 1861, may be taken as the first link in the chain, and up to the present time the report by Tooth, of London, in 1891, of four brothers affected with spastic paraplegia without ataxy, but with affection of the voice and sphinctres, and no other important symptoms, as the last link; all other cases, including those of this series, forming intermediate links. For notwithstanding the differences existing between this series and that described by Friedreich, the heredity, the ataxy, the marked affection of the voice, would strongly suggest, if not indeed, positively demonstrate that they properly belong in the same category, and this being admitted the cases reported by Tooth should also be included, for there is as much difference almost between my series and Friedreich's, as Tooth's series and mine.

FAMILY TREE OF HEREDITARY ATAXY.
reported by
Dr. Sanger Brown.



Explanation of Diagram:— Shaded enclosures indicate Hereditary Ataxy. Squares indicate males, circles females. The numbers to the left refer to the case in the text. The first number to the right the age at death or the present age. + indicates deceased. The last number indicates the age at onset.

The comparative absence of the various neuroses among the relatives of the individuals composing this and other series, and among the individuals themselves, has suggested to my mind the probability that the primary defect might be rather in the accessory than in the essential nerve elements, for it is a matter of general belief among neurologists that if hereditary defect of the nervous elements is proven to exist, this is apt to be manifested by the appearance of various neuroses in the family so affected. Here we have, indeed, marked evidence of an hereditary degenerative process affecting the nerve elements, but if the above considerations are valid, not commencing in them. This view is rather supported, also, by the consideration that the defect being transmitted in and confined to a protoplasmic cell, the whole cell ought reasonably to suffer to some extent at least, and furthermore, this view is harmonious with the assumption that the inherited defect is confined to the connective tissue cell, which is effected throughout, but inconsistent with the theory that the primary defect is in the nerve cell, for in the latter case we have to conceive of the inherited defect as being arbitrarily restricted to a mere part of a cell, to wit: the axis cylinder, and that in the face of the generally accepted belief that the nerve cell and its processes are continuous and homogeneous. Then, too, the frequency with which there is considerable jerkiness in the various movements, including nystagmus, suggests a pathological analogy between this disease, and disseminated sclerosis, in which the primary pathological process almost certainly commences in the connective tissue element; in the former the process being more general and less intense than in the latter. In disseminated sclerosis it is easily conceived how a motor nerve current may be suddenly brought up in full career, so to speak, against a sclerosed patch, and with momentary interference force its way through, and thus on to its destination with a corresponding affection of movement. In Friedreich's disease a similar obstruction. though less concentrated and arresting the current more gradually, may be hypothecated with a corresponding motor result. From the foregoing considerations I deduce the corollary that motor defects in this disease are mainly due to interference with the centrifugal paths of the upper nervous segment.

The accompanying diagram represents a series of cases of hereditary degenerative disease of the central nervous system considerably more extensive both in regard to the number of individuals affected, and the number of generations through which it has extended than any that has hitherto come under my observation. I presented essentially the same series a few months since to the Chicago Medical Society, but was then unable to present any of the cases, as I had hoped to do. I am very glad to be able to present two of the cases now, because I am well aware that where a report so extensive is made, so circumstantial, and withal, departing so widely from previous reports, as to rudely disturb, perhaps, existing theories, the skeptical might naturally be expected to mistrust either the capacity or honesty of the reporter.

I have had four of these cases (18, 19, 20 and 21) under observation over a year, and two more (9 and 10) for about nine months, and still another (22) I examined thoroughly three months since, that is since reporting the series to the Chicago Medical Society, and since that time also two cases (5 and 9) have died (and unfortunately, I was unable to get an autopsy). Two others (5 and 15) living at a distance, were thoroughly examined for me by Dr. Norman Bridge, so that in nine of the cases the examination may be regarded as fairly satisfactory.

In all the other cases I have been able to get a definite enough account of the symptoms to enable me to make a diagnosis, and this is not such a difficult matter, because when the disease is well developed it has so many prominent diagnostic features, and because the families among whom it has been distributed have been composed of people of good social position, of good education and superior intelligence.

Case No. 18.—Male, single, thirty years of age, business man of correct habits, with an excellent family history aside from this disease, the hereditary relations of which are readily seen by reference to the chart. With the exception of the effects of the disease now under consideration, the general health has always been good, and the patient, from his childhood up, showed more than an ordinary degree of bodily and mental vigor, but these characteristics were judiciously directed, so that they do not appear to have had any etiological bearing upon his case, and I merely state them so definitely in order to make it clear that in his case, at least, development was normal.

In this case, as in many others of the same kind, the symptoms developed so insidiously, that it is impossible to fix upon a very exact period as marking the onset of the disease. The patient thinks, and this opinion is shared by some members of his family, who, like himself, have made a close study of the subject, that at the age of puberty there was a greater affection of the voice than could fairly be attributed to that physiological phenonenon alone; and it is quite certain that at eighteen he could not walk steadily when fatigued. and would communicate a perceptible movement to any moveable object against which he might happen to support himself.

Weakness did not appear in the legs until several years later, and it has always been distinctly subordinate to the ataxy. Ataxy did not appear in the arms until about three years after making its appearance in the legs. An increase in the knee jerk was an early symptom no doubt, because quite early in its course the disease was pronounced spastic paraplegia by experienced and eminent physicians. A troublesome tendency to choke was a comparatively early symptom, and this has continued down to the present time. There have been no sensory symptoms of any kind, no affection of the sphincters, and no muscular atrophy or trophic disturbance, and no disorder of the sexual functions. For the past year the body weight has been about stationary, but for several years prior to that there had been a gradual decline amounting to about twenty pounds.

The ataxy, impairment of vision (of such a character that patient could read best in a dim light), difficulty in articulation and weakness have gradually increased, sometimes more and sometimes less rapidly, for the past thirteen or fourteen years, until the patient has reached his present condition.

The patient cannot walk without the assistance of another person, and all the time has a marked subjective feeling of insecurity, as if his head must certainly fall violently to the ground. There is distinct weakness of the legs, but I know of no good way of exactly estimating its degree. The knee jerk is much exaggerated, and equal on the two sides, and there is ankle clonus. The skin reflexes appear normal, excepting the cremasteric, which is perhaps subnormal. There is marked ataxy in all voluntary movements, and there are associated movements extensive in range and distribution. Thus, for instance, a voluntary movement of the hand and arm often sets up associated movements in the opposite hand, the head and face. There is ataxic disturbance in the muscles concerned in articulation, including the tongue. with corresponding defect of speech.

There is marked impairment of vision, due to optic nerve atrophy, vision being 20-200. There has been diplopia at times of a few days' duration. There is ptosis when the patient is at rest, but the lids are often voluntarily raised so high as to show the sclerotic above the iris. There is lagging of the right external rectus to the extreme right, but no incoördination in the external ocular muscles, and no nystagmus. The pupils respond to light, accommodation and stimulation of the skin of the neck, but more slowly than normal. There is not much peripheral limitation of the visual field, but there is almost complete color blindness, red only being distinguished with any degree of certainty. Closure of the eyes has no material effect upon the ataxy.[*]

Case 20.—Brother of 18. Age 25, business man of correct habits, and during boyhood a frequent winner of prizes in athletic contests. Excepting that the disease appeared later, has advanced less rapidly, and that the range of tissues involved is more limited, the history of Case 18 may be used for this one. The tendency to choke is absent, and though the first symptom appeared at 18, the arms are not yet much affected.

Here there is marked ataxy in the legs, as shown in the gait, but it would be difficult to demonstrate weakness. The ataxy is not much increased by closure of the eyes, and as already stated, the arms are not yet much involved, and neither have associated movements appeared to any considerable extent. The vision is reduced considerably, and is much better in a dim light than in a bright one, but one would hardly make a diagnosis of optic nerve atrophy from an examination of the disc alone. There is ptosis at rest, and the lid is often raised too high by voluntary effort, but there is no nystagmus. There is obvious, but not great, impairment in articulation.

In *Cases 10 and 17* there appears to have been something like lightning pain, not severe, however; and in 10 there is considerable insufficiency of the rectal and vesical sphincters, though in every other respect the case is practically the same as 18. I might add, too, that in Case 18, during the last months of life, there was marked melancholia, with great emaciation.

Case 22 is a rather backward girl of 8, whose parents at the age of 5 first noticed a tendency to walk upon the toes, which has steadily increased, so that at the date of my examination, there was observed some permanent spastic contracture of the right leg at the knee, with ankle clonus on that side, and greatly exaggerated knee jerks on both sides. No atrophy, ataxy or apparent weakness, and no disturbance of sensation.

For a more complete report of the whole series I must refer to the February number of this year of the *North American Practitioner* and the *Chicago Medical Recorder*, from which it will appear, I think, that Case 18, as here described, with the exceptions here noted, is fairly typical of the series.

Discussion.

Dr. C. K. Mills, Philadelphia, Pa.:—These cases are of great interest, and particularly the part of the paper of Dr. Brown which gives us his view as to the pathology of the disease. Friedreich's ataxia, and a series of cases of a different sort have, I think, a certain bond in common. It is one of the most interesting matters in connection with the discussion of these cases to recognize this bond of union. We have in the wards at the Philadelphia Hospital cases of Friedreich's ataxia, and half a dozen other forms of disease which, I believe, are all hereditary; for instance, the so-called hereditary chorea, idiopathic muscular atrophy, and the association of muscular atrophy with pseudo-hypertrophy, etc. We have had, in my own personal experience also, a few cases of ordinary spastic paraplegia, and of the ordinary type of locomotor ataxia which were, in so far as the history is concerned, hereditary. A most interesting case is a young man, 26 years old, who presents a typical case of the ordinary form of locomotor ataxia, with lancinating pains, disorders of sensation, with ocular and bladder symptoms, etc. In this case the disease began at the age of 14 years. Cases of combined sclerosis or ataxic paraplegia occasionally begin early in life. We should learn to take a more philosophical view of these cases, and while we differentiate more and more the nervous diseases into types, we should be careful not to lose sight of the bond which connects them. A large number of them are due intrinsically to the same tendency to arrest of development. To many of the forms of hemiplegia and spasmodic affections of children these same remarks may apply.

As to the pathology of the disease, I think the views advanced by the author of the paper are of the greatest interest. Dr. James Hendrie Lloyd, of Philadelphia, and others maintain that there is a similarity between cases of Friedreich's ataxia and syringomyelia. Dr. Lloyd believes that if the cases were closely studied a certain percentage of them would be found to be cases of syringomyelia. In a tabulated report by Dr. Crozier Griffith of some 150 cases, a few of the autopsies indicate the pathology to be of this character. In several cases supplementary central canals were apparently present, as well as enlargements of the original canal; or the canal itself was patulous, which, of course, is not the case as a rule.

Dr. F. X. Dercum, Philadelphia, Pa.:—I have seen a number of cases present typical Friedreich's ataxia in which there was loss of knee jerk. We have in our wards in Philadelphia a patient in whom a similar degenerative change in the cord doubtless exists, but with the ataxia there is also associated marked chorea. Whether we have at the beginning a clear understanding of the cases of adult and hereditary chorea is a question, but certainly the facts at hand are very suggestive.

---

[*] Dr. W. T. Montgomery and Dr. Casey A. Wood examined the eyes and made report.

A CASE OF ABDUCTOR PARALYSIS OF BOTH VOCAL CORDS.

Read before the Section of Laryngology and Otology, at the forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY JONATHAN WRIGHT, M.D.,
OF BROOKLYN, N. Y.

The report of the following case is made more with a hope of helping to keep alive an interest in a puzzling subject than with a hope of adding anything entirely original to its literature.

K. T., maidservant, æt. 26, single, came for treatment to the throat class of the Out-Patient Department of Roosevelt hospital on Dec. 29, 1890.

Her family history was negative. She had a moderate alcoholic, but no specific history. Four years previously she began to have almost constant headache. She had pain in the bones and felt weak. She had shortness of breath and palpitation of the heart on exertion. She had some swelling of the feet and hands. At that time she was treated in the hospital under the diagnosis of simple anæmia. She had had similar symptoms since then but had kept at work. The previous winter she had considerable cough and expectoration. She had been run down since summer, and unable to work. For two months she had had cough and expectoration of phlegm. Five weeks before she had fallen in a faint and was totally unconscious for several minutes. A few days later her neck began to feel stiff and numb at the back. She had also numbness and dull pains in the right arm, side and leg, and she limped a little. Three weeks before admission she began to have some choking on swallowing. She felt as though there was something in her throat or behind it. There was no pain, but a deep seated numbness. A week later she began to make considerable noise at night in breathing. She had little or none of this when awake. She suffered some dyspnœa only on exertion. The feet had been a little swollen. She complained of no eye symptoms. She had a little headache. The numbness had grown less. She had some cough. Her appetite was poor. Her bowels were regular and her menstruation was normal. She was sent to the wards of the hospital. Her condition on admission, as noted in the history books of the clinic and the hospital, was as follows:

"She is fairly well nourished; her face is rather sallow and a little pale. When awake her breathing is audible at the bedside, but not loud. It is somewhat stridulous in character. She had some difficulty in talking at times. She seems to phonate, at those times, on inspiration rather than on expiration. This is especially so after a laryngoscopic examination. P. 74, R. 22, T. 99.

"A physical examination of chest show signs of a general bronchitis, especially on the left side. There is some curvature of the spine, with the convexity to the left in the upper dorsal and lower cervical region. There are no points of tenderness. She said she had been so from a child.

"Urine, acid, 1013, albumen faint trace; a few pus cells; no sugar.

"Laryngoscopic examination. The left vocal cord is immovable in the median line. The right vocal cord moves in abduction only throughout about one-third of its normal arc, so that in greatest abduction there seems to be only about one-eighth of an inch between the two vocal processes of the arytenoids. Both cords seem tense (but this is a condition I am never absolutely sure of, the degree of tension varies so much normally in different cases)."

She had noisy breathing at night more marked on inspi ation, but also on expiration. She also seemed to have some dyspnœa at night.

She was very hysterical and it was very difficult to separate her real symptoms from her imaginary ones in the accounts she gave of them.

Her cough and expectoration soon ceased under treatment directed to her bronchitis. She was also put on anti-syphilitic and anti-hysterical treatment with no beneficial result. There was no change in the laryngeal symptoms, either subjective or objective.

Her general health improved very much and she gained a great deal of flesh.

She was finally discharged April 29, 1891, after having been under observation for three and a half months in the hospital. She came again to the Out-Patient Department and I gave her one-sixth of a grain of sulphate of strychnia daily for ten days or a fortnight, with no effect.

On August 19, 1891, she was again admitted to the hospital for a sudden attack of dyspnœa which promptly passed away. She was again discharged two days later. After this she had from time to time attacks of dyspnœa complicated with hysteria and flatulence until April 29, 1892, when she suddenly died from suffocation. During the latter part of the time she was under the care of Dr. H. B. McCarroll, to whom I am under obligations for that part of her history. On the day she died I had an appointment with Dr. McCarroll for a consultation, with the idea of suggesting a thyrotomy and the excision of her vocal cords, having become convinced that otherwise she would die in one of her attacks, although none of them had been alarming. To our great disappointment we were unable to obtain an autopsy and so the case is robbed of much interest and probable instruction.

Three years ago, while interested in some cases of laryngeal paralysis, I reported two of them and gave a summary of the literature of the subject up to that date.[1]

The report of this case may serve as a text for a few remarks upon some experiments made in the last few years which have shaken some of my convictions, never very decided, in regard to the subject.

Although Burger,[2] in a recent very valuable monograph, has reported some cases of tabes dorsalis which very closely resembled the one reported here, I cannot believe that there was in this case any real posterior spinal or bulbar sclerosis, as the laryngeal "crises" were the only ataxic manifestations of the disease.

To quote from my former paper:

"Baümler and Johnson in 1872 and 1873, and later McCall, Anderson and Whipham reported cases of bilateral paralysis of the vocal cords, some of them in the median position, which were due to pressure on one vagus nerve alone. Johnson in another and a very able paper, explained this phenomenon on the strength of the researches of Rosenthal, and Waller and Provost, which were repeated by Professor Rutherford at Johnson's instance. Pressure on the trunk of the vagus may cause bi-lateral palsy, or spasm of one and palsy of the other side of the larynx, by reflex action due to the decussation of the nerve fibres in the medulla, since the vagus is made up of both afferent and efferent nerve fibres, while pressure on the recurrent alone can only cause paralysis of the affected side. This he believed to be the cause of many cases of sudden dyspnœa in thoracic aneurism. Finally he says, 'it is probable that the long continued irritation of the trunk of the vagus may gradually, as in cases of traumatic tetanus, induce such demonstrable structural changes in the nerve centre, as will explain the bilateral palsy which appears to be one of the results of chronic nerve irritation.'"

In the case here reported the curvature of the spine in the lower cervical region with the convexity to the left, would suggest that the body or lateral process of a cervical vertebra might press upon the left vagus nerve, or upon the left recurrent nerve. Krause[3] has recently published experiments which prove that the recurrent nerve contains centripetal as well as centrifugal fibres.

Three years ago it seemed to me that the experiments of Krause, Jeleneffy and others made it more than probable that the median position of the cords in these cases was due to laryngeal spasm caused by irritation from pressure upon the nerve trunks or centres. It certainly seemed very improbable, *a priori*, to think that pressure upon the recurrent nerve, which carries both abductor and adductor nerve filaments should select in so many cases the former for injury. Knowing as we do that the abductors all over the body are the weakest, and that electric stimulation of the recurrent nerves causes contraction of both adductors and abductors, resulting in adduction of the vocal cords, we were prepared to give ready credence to Krause's theory, supported by his experiments, that pressure upon the recurrent nerve causes closure of the glottis by stimulation of all the nerve filaments rather than by paralysis of the abductor filaments alone.

Since then, also, Masini[4] has shown that crystals of chromic acid placed on the recurrent laryngeal nerve of a dog causes tension and immobility of the vocal cord of that side in the middle line. Fränkel and Gad,[5] on the other hand, had shown that gradual freezing of the recurrent laryngeal nerve, which we know decreases nerve irritability, causes also immobility of the vocal cord in the median position. Similarly contradictory are the experiments of Wagner[6] and Katzenstein.[7] The former showed that the median position of the vocal cords is due to the action of the crico-thyroid muscle, which he claims acts as an adductor of the vocal cords as well as a tensor, and being supplied by the superior laryngeal, is not affected by injury or disease of the recurrent laryngeal nerve.

Katzenstein's experiments, on the other hand, demonstrate quite as conclusively that this is not the case.

The most severe blow yet dealt experimentally to Krause's spasm theory with which I am familiar, is contained in the recent work of Dionisio.[8] He very ingeniously adapted a thin rubber bag to the glottis of a dog, between the vocal cords, and by connection through a rubber tube with a graduated scale constructed a laryngeal manometer by which he could read the degree of compression exerted on the column of water by the abduction and adduction of the vocal cords. He noted the oscillations of the column of water during natural expiration and inspiration.

He then exerted gradual homogeneous and concentric pressure on the recurrent nerve.

He observed, "that according as the duration and intensity of the compression of the nerve increased, the inspiratory and expiratory oscillations of the manometric column decreased; moreover the latter was little by little lowered several centimeters." He then compared the results of electric stimulation with those of compression, and concluded that: "Gradual and continuous pressure exerted upon the inferior laryngeal nerve, in place of augmenting the force of adduction of the vocal cord diminishes it. The force with which the cord was adducted in consequence of the slightest electric stimulation of the nerve, just sufficient to cause a gentle contraction of all the muscles with a prevalence of the adductors over the abductors, is much superior to that which the same cord shows during compression of the nerve. From this it is permissible to conclude that adduction is not caused by spastic contraction due to pressure, because if it were, the vocal cord ought to show an adductor force superior to that which is shown in the slight movements of expiratory adduction, and not inferior to it as really happens."

Naturally it may be objected that in pathological compression from tumors and the like, the pressure is exerted very much more gradually than is practicable in experiments, and that some chronic inflammation may set up in the nerve which may *possibly* cause stimulation and not paralysis.

Moreover, the objection of reasoning from animals to man, or from one animal to another, is always to be considered. I do not urge these objections for more than they are worth, but it is unscientific to disregard even the slightest rational objection.

It seems, therefore, that we are thrown back again upon that very vague and unsatisfactory law laid down by Rosenbach and Semon, that there is a specific vulnerability in the nerve fibres supplying the posticus muscle. This, I must confess, seems very unsatisfactory because it is difficult of conception, and, as far as I know, without analogy elsewhere in nervous pathology. Of course, it is quite possible, in view of the conflicting experimental evidence, that the median position may be due to either cause.

In reading the literature of the subject I have been impressed with the belief that at least one point has been overlooked or not duly considered, viz.: In any case of median position of the vocal cords due to spastic contraction, practical paralysis of the posticus muscle must ultimately occur, for the inability of its fibres to effectively contract must soon cause muscular atony. After a comparatively short time, also, we must expect fixation of the joint, so that any subsequent atony of the adductors, or any subsequent complete annihilation of the function of the recurrent, will not result in the cord assuming the cadaveric position, as occurs where the injury to the nerve causes more prompt destruction of complete function.

Lately, this belief, founded upon experience elsewhere in the paralysis of joints, has been confirmed by the report of a case[9] in which, there being double posticus paralysis with dypsnœa, one recurrent laryngeal nerve was divided, with the idea that this would produce complete paralysis of the laryngeal muscles on one side, which would place that vocal cord in the cadaveric position and so allow room enough for respiration. To the surprise of every one, no change occurred after the operation. Although the reporter offered no explanation, the one above suggested seems to me extremely probable.

Hence, in such a case as here reported, I believe that extirpation of the vocal cords would be a justifiable operation. It is one which has been satisfactorily performed in horses for "roaring," although the results have not been uniformly successful in regard to future service. The operation in the human patient, however, would be for the preservation of life without the discomfort and danger of wearing permanently a tracheotomy or an intubation tube.[10]

Discussion.

Dr. G. V. Wadlen, Indianapolis, in opening this discussion, expressed his pleasure in witnessing the tendency in the papers and current writings to accept the doctrine that there was no such thing as an organ or tonsil, having placed himself on record several years ago that there was no such thing anatomically speaking. He only wished to call attention to the causation and treatment of these growths, and their frequent diseased manifestations. Believing as he does that the catarrhal process originates always in childhood, and recognizing the poisonous nature of the secretion as taught in these papers he finds the reason for the fauces and especially the side of the fauces over which these secretions flowed to exhibit trouble was that nasal discharges are directed to these localities by the prominence of the posterior of soft palate. Therefore there being no such thing as a healthy tonsil, they show these various tendencies to disease and should be eradicated, and never by cauterization if it is possible otherwise.

Dr. Seiss, Philadelphia, thinks tonsils are definite physiological entities, as the glands occur in the lower animals, which never suffer from non-traumatic tonsillar enlargement. Denied that tonsils treated by galvano-puncture are apt to give subsequent trouble. Has seen many cases cured by this treatment. False membrane depends on intensity of irritant, occurs from steam scalds, the poison of influenza, etc. Pathogenic bacteria vary in malignant fever, and Jacobi taught years ago that a simple "follicular tonsillitis" may in another case set up "malignant diphtheria."

Dr. Jonathan Wright remarked:—There certainly are anatomical structures in the normal throat constantly from which the tonsillar hypertrophy follows. They are the folds of the mucous membrane supplied by a collection of muciparous glands. In these folds of mucous membrane there are lymphoid follicles, collections of round cells from which the tonsil afterwards grows.

Bayinsky, of Berlin, and Coucetti, in Italy, have lately demonstrated the Lœffler bacillus in the cases of nonsystemic croupous rhinitis. I am at sea in regard to the diagnosis between malignant (diphtheretic) and benign croupous rhinitis.

DOMESTIC CORRESPONDENCE.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

It is well established that the United States has within her borders many valuable and potent mineral springs; and every careful physician should endeavor to recall his experience and investigations with reference to the climate and medical typography and the therapeutic value of the mineral waters of his locality. With the desire to add my mite to this important subject—the therapeutical value of the mineral waters of our country, I respectfully submit the following:

PRACTICAL OBSERVATIONS ON THE MEDICINAL PROPERTIES OF THE MINERAL WATER OF COOPER'S WELL, HINDS CO., MISS.

In the month of September, 1892, I derived substantial benefit from the pure and bracing air, at an elevation of about 650 feet above the level of the sea, and the medicinal properties of the mineral water of Cooper's Well, Mississippi, after a prolonged illness in New Orleans, La.

The mineral water of Cooper's Well (situated about the geographical center of the State of Mississippi) is prompt and decided in its therapeutical effects, which may be classified as 1. Purgative; 2. Diuretic; 3. Diaphoretic; 4. Tonic Alterative and Restorative.

---

[9] "Observation pour servir a l Étude de la Stenose laryngée néuropathique"—par le Dr. Albert Ruault, Archives lubrucations de laryngologie, No 1, 1892.

[10] I do not wish to offer this suggestion without stating that I have made no search in literature for any similar previous suggestion or even trial. A record of both, therefore, may exist.

1. *The Purgative effects* are due chiefly to *magnesium sulphate* (Epsom salts, about 24 grains per gallon); *Sodium sulphate*, (Glaubers salt, about 15 grains per gallon); and *Calcium sulphate* (about 32 grains per gallon).

2. *The Diaphoretic effects* are due mainly to the peculiar salts and to the *potassium sulphate* (about 6 grains to the gallon), *sodium chloride* (about 9 grains to the gallon); *Calcium chloride* (about 5 grains to the gallon); and *Magnesium chloride* (about 3½ grains per gallon of the water).

3. *The Diuretic effects* of the water must be referred to the action of the preceding salts upon the sudorific glands of the skin.

4. *The Alterative Tonic and Restorative effects* must be referred to, *a*. The peroxide of iron; *b*. The salts of calcium. And to the alterative effects of the salts of magnesium, sodium and potassium.

The combined effects of the saline ingredients, amounting to about 106 grains to the gallon (about one-fourth of an ounce per gallon), are manifest in the dark green copious evacuations from the bowels, the frequent and abundant excretions from the kidneys.

Both the liver and the kidneys are freely acted upon by the water, and at the same time the noxious abnormal products of the bile, torpid liver and deranged functions of the spleen, of the diseased and altered blood are eliminated by the gastro-intestinal mucous membrane.

The water of Cooper's Well, according to my personal observation and investigation, *will when used* under and by the direction of skilful physicians, prove highly beneficial in the following diseased states.

1. Anasarcan. 2. Ascites. 3. Alcoholism, acute. 4. Alcoholism, chronic. 5. Bright's disease. 6. Cardiac dropsy (valvular disease of heart). 7. Hepatic dropsy, arising from chronic hepatitis. 8. Renal dropsy, arising from lesions of kidneys. 9. Calculus (uric acid and oxalates and urates). 10. Jaundice, arising from hepatic derangements. 11. Jaundice, arising from the prolonged action of the malarial poison in the liver, spleen and blood. 12. Gout. 13. Rheumatic gout. 14. chronic malarial poisoning. 15 Rheumatism, chronic. 16. Diarrhœa, chronic. 17. Constipation, chronic. 18. Dyspepsia. 19. Nervous exhaustion, arising from various causes, as the prolonged action of febrile poisons, especially of the malarial poison; prolonged mental exertion, the prolonged heat of summer, the abuse of alcoholic stimulants and narcotics.

This water is contra-indicated in the *secondary diarrhœa* of *phthisis*, and in fact this disease (*consumption*) is not benefited, but rather injuriously affected by Cooper's Well water. However, phthisical patients may derive benefit from the elevation, cool climate, and pure, bracing air, and exercise over the beautiful hills and ravines, covered with lofty *long leaf pines*.—Respectfully yours,

JOSEPH JONES, M.D., LL.D.
Prof. Chemistry and Clinical Medicine,
Tulane University of Louisiana.

156 Washington Ave., New Orleans, Sept. 25, 1892.

BOOK REVIEWS.

A TEXT BOOK OF MORBID HISTOLOGY FOR STUDENTS AND PRACTITIONERS. By RUBERT BOYCE, M.D., with 130 colored illustrations. New York: D. Appleton & Co. 1892.

In this very excellent work the author without unnecessary verbiage gives a good account of the chief histological changes met with in disease. The arrangement of the subject matter is according to the method adopted by Prof. Horsley. The illustrations are micro-photographs, and ar exceptional as reproductions of the histologists' work of th author and others. As an aid to those who assist the ever day general practitioner in making accurate diagnosis o obscure diseases, this book is at once indispensable. Fo the student it is full of object lessons.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. By JOHN V. SHOEMAKER, A.M., M.D., Philadelphia. D. Appleton & Co, New York.

To those who know Dr. Shoemaker it is by no means surprising that this work upon diseases of the skin should be by far the most excellent that has yet appeared in America. It is fully up to date, well illustrated, and from a therapeutical standpoint is certainly irreproachable. Some of the pathological points are somewhat open to criticism, but not sufficiently so to detract greatly from the merit of the work. To the student of dermatology as a specialty, as well as to the general practitioner, this work will prove of great value.

GENITO-URINARY AND VENEREAL DISEASES. CHETWOOD.

This little volume is one of the students' quiz series in process of publication by Lea Brothers & Co. It is perhaps likely to be useful to the student during the cramming process preceding examination, but it is very apt to lead him into serious error if he remembers much of its teachings after entering practice. Quiz compends should contain few dogmatic assertions; this one is full of them. The statement is made, for example, that total extirpation of the involved glands prior to suppuration in chancroidal bubo, is not apt to prove successful. On the contrary, when properly done, it is quite often successful.

Another point worthy of attention is the absolute and unequivocal condemnation of the electrical treatment of stricture. There is a tendency to follow arbitrarily the teachings of Keyes. It may not be known to the author, but there are other authorities on genito-urinary diseases whose work is quite as reliable as that of the gentleman mentioned. Leaving out of the question the element of dogmatism, which is so paramount in this work, it is really an excellent little volume for the purpose for which it was designed.

OFFICIAL DISINFECTION SCIENTIFICALLY DIRECTED.—The medical profession has not a very lively admiration for the ordinary official disinfection and fumigation. While we do not, as a general rule, care to antagonize those operations, in the feeling that "they may possibly do some good"; neither do we care to very emphatically endorse them as matters of prime importance; we have become mildly agnostic in the matter. And this is chiefly because our rulers have seldom made provision that those official functions shall be under medical supervisions. Those acts have too often been done in a perfunctory manner.

The New York City officials have made a new departure, in those matters, that may serve to commend them again to medical confidence—after having driven it from them along with such men as Jacobi, Stephen Smith, Prudden, Janeway and many others. The Health Board has placed an expert bacteriologist in command of the disinfecting corps, and ten physicians will be employed under him, each of them having the oversight of a given district. Formerly the disinfecting was performed by laymen, sixteen or more in number. Dr. Herman M. Biggs, of the Carnegie Laboratory, will be the commandant of the somewhat fancifully entitled "division of pathology, bacteriology and disinfection"; and he will be known as the "bacteriologist-in-chief" with a salary of $3,000 per annum, or until some politician can put him out, after the cholera season is over. However that may be, the measure must be regarded as a wise one, and the appointment of Dr. Biggs as being in the interest of the public health. It gives dignity and prominence to official preventive work, elevating the "pot of brimstone" of the health officer to the position of a scientific symbol.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1274, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 8, 1892.

PROTECTIVE INOCULATION AGAINST CHOLERA.

The recent appearance of epidemic cholera in some parts of Europe has caused the publication, in various Continental medical journals, of many articles on the subject of acquired immunity to cholera as a result of protective inoculation of the ptomaine produced by the cholera vibrio. The subject is one of great interest in view of the high mortality of cholera, as well as the probability that this fall will not witness the extermination of the disease in Europe, and the spring of 1893 may, as has occurred in past epidemics, witness a renaissance of the present epidemic, that we are now informed is dying out.

In 1885 DR. JAIME FERRAN presented a paper to the French Academy of Sciences, in which he reported the results of experiments that showed that cultures of the cholera vibrio, injected subcutaneously in animals in suitable doses, produced certain local phenomena and rendered the animal immune to more virulent cultures of the vibrio, that would rapidly kill an animal that was not so protected. Similar mild injections in man produced phenomena analogous to those observed in the animals, and he inferred that if the latter were protected by these injections the former would also be protected. Subsequently this bacteriologist announced that it was the toxic product of the vibrio that produced the effects he had reported, because injections of cultures of the cholera vibrio in which the microörganisms had been killed, produced the same results as the cultures he had first employed. And still later he obtained an alkaloid from cultures of cholera that produced when injected similar effects to those he first published. A culture of the dead vibrio conferred a tolerance that resisted the effects of the living bacillus, and well-known methods isolated from cultures of the latter a ptomaine that produced a similar tolerance.

During the cholera epidemic of 1885 in Spain, FERRAN inoculated many persons with the protective culture of the vibrio, and the statistics of cholera occurring among uninoculated persons were 76.95 per 1,000, with a mortality of 33.58, while among the inoculated the attacks were 12.69 per 1,000, and the deaths 3.41. His methods were investigated by scientific commissions from several countries; but some of these investigators, while acknowledging the efficacy of the inoculations, condemned FERRAN for keeping secret his methods of preparing his inoculating fluid.

In 1888 GAMALEIA reported to the Paris Academy of Medicine that he had obtained from cultures of the cholera vibrio *a toxic substance that killed in* certain doses, but in smaller doses rendered an animal immune to choleraic inoculations.

More recently KLEMPERER has rendered animals immune to cholera by treating them with modified cultures of the cholera vibrio. He modified his cultures by keeping them at high temperatures for some days, or by passing a constant electric current through them for some hours.

HAFFKINE has also published a method by which he increases the virulence of the vibrio so that it will produce in animals symptoms that are similar to those produced by the disease in man; though an interesting fact is mentioned by him, that the symptoms in the animals do not appear for a few days, and occasionally the period has extended to two months. Like FERRAN, he cultivates the vibrio in guinea-pigs, and injects cultures of the vibrio under the skin, causing just such local phenomena as FERRAN noted, and rendering the animal immune against inoculations of cholera made in any way whatever. He attenuates this virus and uses it for protective inoculations in animals and in man. In the latter the symptoms are similar to those observed in the inoculations made by FERRAN. With these inoculations also, a second does not produce the constitutional or local phenomena observed with the first; and it is inferred that as the animals remain immune to cholera, so does a man who has been inoculated.

The inoculations are not attended with any grave disturbance of health; they can be practiced on human beings with perfect safety; and by a subsequent subcutaneous injection it is always possible to determine whether the immunity conferred by the first injection has persisted.

All later observers have confirmed FERRAN's original claim that the ptomaine produced by the cholera vibrio would, if administered to an animal in suitable doses, inhibit the subsequent production of cholera in that animal. So to him is due not only the credit of the discovery, but of applying it as a means of protection against cholera, and the statistics he published showed its efficacy for that purpose.

SCHOOL HOURS.

Among the many things of which the American people are justly proud, there is nothing that takes precedence of the public school system that is now quite general in almost, if not all, the States. In fact, the excellence of the common school is a valuable indicator of the moral and social status of any community. Hence, a belief is general, that a fair common school education for every boy and girl is the best possible preventive of vice, pauperism and crime.

With the spread of intelligence there is a consequent aggregation of people in cities and populous centres, and in the population centres the saying is trite that a disproportionate number of the leaders of enterprise, alike in commercial and professional pursuits is drawn from the men who received their early education in country schools.

The reason usually given for the country boy being able to overtake the one reared in a city, is, that he has had the benefit of unlimited out door exercise, which has developed him into a more hardy, enduring and robust man, all of which is no doubt true and is justly a prominent factor in the case, but another, and we regard it as a most important reason for his superior physical and mental development, is that the country school boy has had the benefit of better school hours. A sleep of nine or ten hours fits him for a hearty breakfast, home chores and three hours' study, the latter interrupted by a fifteen minute recess in which to take a run and in his own way relax and stretch his nerves and muscles. So that when the clock hands point to the noon hour he is downright hungry and ready to partake of a good wholesome picnic dinner, which he has brought with him from home.

This bounteous noon repast, seasoned with the sauce of repartee, takes from fifteen to twenty minutes of what seems to him to be the very best part of the day. The remainder of this noon hour is given up to play.

This noon hour, with its provident dinner, supplies the nutrient pabulum for recuperation and growth that more than aught else makes the muscle, nerve and bone which enables the country boy in later years to forge ahead of his fellow, whose studies during his school days have been a daily grind of five or six hours, almost wholly taken up with recitations, broken only by a fifteen or twenty minute recess, which is too frequently spent in efforts at catching up in some delinquent study.

After school recitation hours the city boy has dinner, or more properly a lunch all by himself. The indicator in his stomach has long since announced the hour, and not being gratified, a sense of listless weakness has taken the place of hunger, so that his eating is too frequently without relish. Then a little rest, not play, and he is at his books again, preparing for the morrow's recitations. Such is his round for five days in the week.

This method of feeding the developing boy and at the same time working him to the limit of his mental capacity is the stunting factor that in after life places him at a disadvantage with the noon fed boy of the country.

The adage that "an army marches and fights on its belly" is equally applicable to the growing boy and girl. They thrive and study best when their stomachs are fed the best, and this can only be accomplished by the noon feeding hour intermission, and a corresponding *regulation of study and recitation hours.*

This suggested change does not meet with the favor of teachers, mainly, we think, because it lengthens their limited working hours. This reason should have no weight whatever in the consideration of a subject of such vital importance as the one to which attention is directed.

QUARANTINE.

The fear of invasion by cholera has subsided and quarantine appliances to interior cities have been raised.

The disagreeable features of the latter were in many instances quite irritating and detrimental to commercial pursuits, but in almost all instances there was a good natured submission to the health authorities, which indicated a willingness to bear personal discomfort and inconvenience for the greater good that was to accrue to the public at large.

While the official authorities were in some cases criticised for apparent extravagance and harshness in their measures, the motive and purpose was *so* important as to be an apparent justification for the act. Commendable promptness was characteristic in every direction, and as a Nation we are to-day in a condition for congratulation that the menace which so seriously threatened our welfare has been so effectually stayed.

Some important lessons were learned by the people. First, that the science of medicine is alert and progressive, showing that it has, since the last visitation of cholera, discovered the method of infection by that disease, and also a rational means for its control.

Having made these discoveries and practically demonstrated their correctness, it will hereafter become an actually criminal act for any civilized government to permit of a spread of this highly infectious disease.

This occasion has taught that in order to an effectual protection of our American people, the National Government must assume the duties of coast, as well as interstate quarantine measures, and all State and municipal methods must be subservient to the control of the Nation's government officials. Furthermore, the American people have had their eyes widely opened to the enormity of the pauperism, imbecility and crime that is being transported in bulk to our shores.

This iniquitous business cannot be stopped by States or municipalities, but like an effective quarantine must be in the hands of and controlled to the extent of indefinite suspension by the National Government.

In this connection the report of SURGEON J. B. HAMILTON, of the U. S. Marine Hospital Service, on the recent quarantine at New York, published in our current issue, contains matter of great interest and value.

We now know enough to know that hereafter Nations should be held responsible for the existence and spread of this destroying disease.

Cholera can be as effectually eradicated as smallpox or typhus fever. Let every member of the American Medical Association take it upon himself to see that the Member of Congress representing his district is thoroughly informed on this subject. There is no possibility of his knowing too much about the dangers of wholesale ship and fleet loads of immigrant paupers, imbeciles and criminals with their accompaniments, including cholera.

THE FALSITY OF NOSTRUM DEALING.—The *Positive Medicator*, June, has formulated the following conclusions as the result of a very full knowledge of the ways and means of the patent-medicine vendors:

1. They claim to be specifics, which they are not.

2. The consumer pays an excessive price for a secret preparation when, were its formula know, the same preparation could be prepared and sold by his druggist at a reasonable figure.

2. Simple remedies are clouded in secrecy and sold as valuable new discoveries, which they are not.

4. Nostrums interfere with legitimate pharmacy, and being sold by dry goods bazaars, rob the pharmacist of his right alone to compound simple remedies for simple ailments.

5. Their selling value depends not upon their merit, but entirely upon their being pushed by advertising, which advertising in the end the consumer has to pay for.

6. There is no question but that the manner of advertising many nostrums is injurious to the public good. Ignorant people with slight illnesses are made to believe that they are in dangerous conditions and frightened into buying and consuming stuff which may not at all be suited to their cases, and which they use at an excessive cost to their pocket-books and general health.

From the above statement it will be seen that it is practically impossible for the nostrum-maker to say a true word in any of his published statements.

One ingenious calculator has figured out the cost of production of a dollar bottle of advertised medicine, and he has found that the utmost of drug-value that the manufacturer can afford to deliver to the sick person is ten cents. In other words, ninety cents out of the dollar, paid by the consumer, are necessarily absorbed by the proprietor, the wholesale druggist, the local dealer and the newspapers and other channels of spreading the lying claims of the nostrum, before the deluded patient receives his dime's worth of noxious liquid. And doubtless it is better for the patient that he gets that small return for his dollar, the less he gets for his money the better off he will be.

ERRATA.—In the issue of September 17, page 335, the heading of S. C. Ayers' article should read "Embolism of the Central Artery, *or* Thrombosis?" instead of *a* thrombosis.

THE ESTABLISHMENT OF A NATIONAL QUARANTINE STATION NEAR NEW YORK HARBOR.

BY JOHN B. HAMILTON, M.D., LL.D.,

SURGEON U. S. MARINE-HOSPITAL SERVICE, FORMERLY SUPERVISING SURGEON-GENERAL M.-H. S.

THE JOURNAL has secured a copy of Dr. Hamilton's report on the construction of "Camp Low." It is interesting from a sanitary point of view as being a report of the first camp constructed in the United States for cholera suspects, and the rapidity with which the work was accomplished was itself a feat worthy of notice.

REVENUE MARINE STEAMER "U. S. GRANT,"
OFF CAMP LOW, NEW JERSEY,
SEPT. 20, 1892.

THE HON. CHARLES FOSTER,
SECRETARY OF THE TREASURY, WASHINGTON:

Sir,—I have the honor to report the establishment, according to your orders, of the National Quarantine Station, "Camp Low," on the government reservation at Sandy Hook.

RAISON D'ETRE.

The reason for the existence for this establishment was the presence in New York harbor of several vessels infected with Asiatic cholera, having on board a very large number of passengers exposed to the danger of infection, and for whom the provisions made by the health authorities of the State of New York were entirely inadequate. In particular, the passengers from the steamer "Normania," of the Hamburg-American line, were in quarantine for several days, and each day members of the crew were taken sick with cholera. These passengers being detained on board, were constantly subjected, on the one hand, to the terrors of Asiatic cholera, and the hardships of rigorous confinement on the other. Although detained in quarantine, these passengers, most of them American citizens, managed to communicate their unfortunate condition to the public; and American sympathy, always responsive to human suffering, was quick to heed. The Government undertook to supply the deficiencies of the local quarantine at New York, and by your direction I examined the New York quarantine stations at Hoffman's and Swinburne's Islands, and found that Hoffman's Island, the only station to which persons from infected vessels could be removed, was crowded with detained emigrants; that no more could be accommodated, and that no provisions whatever had been made for cabin passengers. More than ten thousand steerage from European ports infected with Asiatic cholera were either on their way or were booked for passage, and ships recently arrived had lost many on the voyage. Under the stress of this menace the Government had no alternative, and by your further direction, I next inquired what measures of precaution could be undertaken by the Government to aid the State of New York in what threatened to become one of the most calamitous years of the Republic, in averting the prospective invasion.

You placed the U. S. revenue steamer, "Grant," Capt. Thos. S. Smyth, at my disposal, and her officers rendered most valuable coöperation. In examining New York Bay and vicinage, in company with Medical Director Gihon, U. S. Navy, and Dr. John H. Rauch, it was seen that Horse-shoe Cove, off Sandy Hook, afforded a perfect anchorage for vessels, and the land opposite being a Government reservation, and no important village or settlement near, afforded an eligible site on which to establish a quarantine camp, at once easy of access and easy to guard. Fortunately, the old wharf of the New Jersey Central R.R., on which was built a warehouse, was in an excellent state of preservation, and in such condition that it could be easily made the initial point for the new buildings, on which the location of the proposed camp can be seen.

THE CONSTRUCTION OF THE CAMP.

On Friday, Sept. 9, 1892, the steamer "Grant" anchored in Horse-shoe Cove, and with Lieut. Levis and the ship's carpenter, U. S. R. M., measurements of the wharf and buildings were taken. That evening you accepted the proposal of Mr. Austin Corbin, president of the Long Island Railroad, to build the necessary buildings according to my suggestions. That night I spent in writing memorandum requisitions for supplies, and the next morning a force of 150 carpenters, under the direction of Mr. C. M. Jacobs, C. E., and Mr. Cummings, were on the ground, and the buildings were erected with surprising rapidity. These comprised a large dining hall, with a capacity of seating 500 persons; a storeroom for the commissariat; a kitchen; three pavilions; a telegraph office; a baggage-room; a hospital; a laundry; a building for the dynamo; Surgeon Commandant's office; quarters for the correspondents. The railway tracks between the pavilions were of great use, not only in the construction of the Camp, but afterwards in its administrative functions. Over four hundred thousand feet of lumber were used in the construction of the buildings, and they were completed on Saturday morning, September 17.

The dimensions of the buildings were as follows:

Pavilion A	18x343 feet.
Apartments	South 47 feet. North 47 feet. Total, 94 rooms.
Pavilion B	13x313 feet.
Apartments	48 single.
Pavilion C	16x330 feet.
Apartments	South 44 feet. North 23 feet. Total, 63 rooms.

Making a total of 209 staterooms.

Telegraph Office	13x25 feet.
Press Office	10x40 and kitchen 10x13 feet.
Laundry Building	13x64 feet.
Dining Hall	34x96 feet.
Electric Light Building	12x28 feet.
Baggage Room	36x60 feet.
Commissary Building	18x36 feet.
Pantry and Kitchen	27x35 ft.; extra kitchen, 12x23 ft.
Surgeon-Commandant's Room	13x30 feet.

In addition to the foregoing there were 3,006 feet of sidewalk laid; 4 water closets made; 58 latrines built; 100 tent floors 12x14, and 200 tent floors 10x12 feet were made ready to be placed in position.

On Sunday, September 11, 400 wall tents, previously shipped by the War Department, were set up by the United States Artillery from Fort Hamilton by order of Maj. General O. O. Howard, and speedy provision was made for the early occupancy of the Camp.

After the rush of construction was over, a few carpenters were retained to extend the pavilions. By this means it was intended to do away with the necessity for many tents.

WATER SUPPLY.

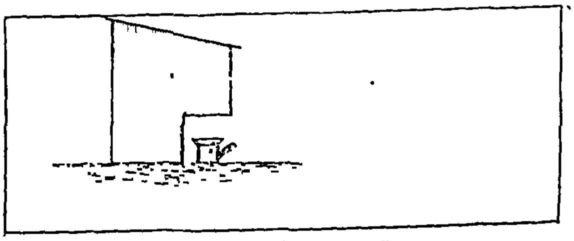
Abundance of fresh water is obtained on the Hook by driven well, and the old railway tank was utilized as a source of pressure, and water was piped to the various buildings.

MACHINERY.

Mr. Corbin caused the electric light plant formerly used at Rockaway Beach to be removed and put in position; and after the third night the work of construction was carried on at night by its aid. This has since been used for lighting the Camp. A steam pump was placed at the old tank house to keep up the supply of water in the tank, and another pump was placed near the dynamo on the wharf and supplied with 500 feet of hose, with sea water connection, to be used in case of fire. I made a contract with the Troy Laundry Co., of New York, to furnish and place in position ready for running, a laundry plant capable of washing for 500 persons a day. This machinery comprised stationary tubs, an engine, two washing machines, a centrifugal wringer, a mangle and drying racks. This was completed according to contract within forty-eight hours, by the men working night and day.

LATRINES.

In a Camp intended to contain suspects from ships infected with the Asiatic cholera, the construction of the latrines and their subsequent management are points of the first importance, for as is well known, the surveillance of persons suspected of cholera must include a watch of the frequency of their bowel movements. In the plan which was finally adopted, I availed myself of the advice of my friend, Lt. Col. Geo. M. Sternberg, Surgeon U. S. Army, and a delegation from a Committee of the New York Academy of Medicine, consisting of Drs. Loomis, Stephen Smith, Jacobi, Janeway and Allen McLane Hamilton. It was urged by Dr. Jacobi that the use of earth closets or chambers in the staterooms would make it impossible to ascertain quickly what person in the camp was suffering from diarrhœa, a point which only needed to be stated to be self-evident; therefore latrines were constructed in such a way that the dejecta was received into a pail, and the little houses themselves placed between the rows of corridors and tents in such a position that the patrolman could easily keep them under observation.



Section of Latrine, Camp Low.

Galvanized iron pails of a capacity of two gallons were provided to receive the dejecta, and milk of lime was ladled into these pails by the patrolmen, who were instructed to systematically inspect them while on their beat. At the same time they were instructed to report to office any person making the second trip to the latrine from his stateroom or tent. Other attendants were directed to mop the seats twice a day with bichloride of mercury solution.

HOSPITAL.

The hospital was constructed in more careful finish than the barracks and was intended for persons falling sick or being injured while in camp. Cholera patients, when found, were removed to and kept in tents near the hospital, and isolated from the remainder of the camp.

PATROL.

To prevent straying of the detained persons, the Honorable Secretary of the Navy, directed the detail of 211 marines under the command of Major Huntington, who drew a complete cordon sanitaire at a safe distance from the camp and maintained a regular patrol. This arduous duty, necessary for this temporary camp, which involved considerable hardship upon the officers and men of Major Huntington's command, could readily be obviated if the Government shall finally conclude to establish a permanent station, by the erection of a brick wall and the dredging of an inner moat.

SEA PATROL.

The sea patrol was a matter of much less difficulty, and, for the first few days, was performed by the steamer "Grant," Capt. Thos. S. Smyth, which officer also detailed Chief Engineer F. H. Pulsifer to aid in making his first purchases, and in various other ways aided in the construction of the camp. The Hon. B. F. Tracy, Secretary of the Navy, detailed the Monitor "Nantucket," Captain Book, with two steam launches to continue the sea patrol and relieve the "Grant."

THE EXECUTIVE FORCE.

At first I was the only officer, but when the Camp commenced to receive refugees turned over by the health officer of New York, the force consisted of myself as Surgeon-Commandant of the camp, Surgeon W. H. H. Hutton, M. H. S.; Passed Assistant Surgeons Wasdin and Stoner, and Hospital Stewards Rœhrig and Stearns. At my earnest solicitation the veteran sanitarian John H. Rauch, M.D., consented to remain as sanitary adviser and cholera expert. The remainder of the force consisted of cooks, carpenters, one plumber, and about forty-five laborers. These were employed in continuing the barrack extension and policing the camp. At first we were short-handed and attempted the employment of refugees, but it was found that they could neither be kept at work nor could they be made efficient. Ten sailors uniformed were therefore engaged as an additional force and were employed exclusively in sanitary work. My experience has shown that sailors are better disciplined and can be kept on such duty much better than the ordinary laborers. Mr. Nimmo, an interpreter and medical student, was made the foreman of the disinfecting corps. It was from the first deemed necessary to have female attendants to look after the welfare of the female refugees, and perform such other duties as might be required of them, and Mrs. Dunkinson, of Geneva, New York, was given supervision of their duties. Surgeon Henry W. Sawtelle relieved Surgeon Hutton, and I turned over the command of the camp to him September 22, 1892.

AERATION.

It is well known that aeration is one of the most effective means of disinfection, and for that purpose 2,000 ft. of clothes line was placed in position to enable refugees to ærate their baggage.

SUPPLIES.

The first supplies for the camp were received by the New Jersey Central R. R., but the local health authorities of New Jersey threw such obstacles in the way of trains as to make it impossible to obtain supplies with regularity or certainty. The steam tug "Talisman," Capt. C. H. Winette, was chartered, to be entirely at the service of the commanding officer of the camp, and make such trips to New York City as should be deemed desirable. Lieut. Wm. J. Herring, U. S. R. M., of the Str. "Chandler," whose headquarters were near the barge office, kindly consented to purchase miscellaneous supplies, and this officer is entitled to the highest commendation for the faithfulness with which he performed this extra duty.

GENERAL.

Should the Government at any time take this for a permanent station, a wall directly across the Hook to the Atlantic, marking the east and west boundaries of the quarantine, would not only obviate the necessity of a military guard, but would allow persons detained to go through the cedar grove back of the camp, and thus add materially to their facilities for recreation while undergoing detention.

The barracks could be weatherboarded and plastered, and heated by steam when necessary. A crematory should be built in the vicinity of the hospital. No isolation ward is necessary, as tents with flies, properly floored and heated by stoves, are better managed than isolation wards, which with every precaution are likely to themselves become centers of infection.

It is obvious that the establishment of this camp met a necessity arising from the great number of immigrants from infected ports massed in the harbor of New York; without it great hardship and greater loss of life must have inevitably resulted, not only among the unfortunate immigrants but in cities and towns near by as well as those remote from New York. The officers engaged in the work have entered upon it with great public spirit, fully imbued with the intention, at whatever risk to themselves, to spare no effort in protecting the country against a great calamity, and I am safe in predicting the final report of the Surgeon-Commandant will show the superiority of National methods in which the whole country have an interested voice, over those which formerly obtained.

There is no question of the power of Congress to legislate in the matter of National quarantines, and it is no argument against the exercise of that power to show that heretofore Congress has only undertaken to supply the deficiencies of State quarantines. Congress has not formally relinquished its power, nor could it do so; it has only failed to use it. When a fringe of States along the Atlantic seaboard comprised almost the whole of the United States, the necessities were different from the present conditions, when the center of population has been removed to the Mississippi Valley. It is inconceivable that one State alone should continue to conduct protective measures, according to its own methods, without regard to the wishes of other States, when all have common interests and are mutually interdependent.

But even more than economical considerations or convenient administration is the great relief to those poor suffering people, huddled together on a ship lying at anchor. They have nothing to fear more deadly than the fatal "crowd poison." Close quarters at sea may be made endurable by the forced ventilation, but lying at anchor the steerage air soon becomes stagnant and poisonous.

I am, sir, very respectfully, your obedient servant,

JOHN B. HAMILTON,
Surgeon U. S. M. H. S.

THE Court of Appeals of Kentucky has recently decided that syphilis, pleaded in answer to an action to recover damages for breach of promise of marriage, is a complete defence, following the decision of the Supreme Court of the State of North Carolina, in which the same defence was interposed and sustained in a similar action.—*Weekly Medical Review.*

DR. JENKINS, health officer at New York, and Dr. Wm. Randle, surgeon of the port of Philadelphia, are both from Mississippi.

SELECTIONS.

The Conical Corky Spines of Zanthoxylum.—The "Annals of Botany" for July contains an interesting paper by Mr. C. A. Barber, B.A. (Superintendent of the Agricultural Department of the Leeward Islands), on the corky spines of *Zanthoxylum*. The author traces the development of the corky spines of *Z.alatum*, as observed in fresh material supplied by the authorities at Kew. The corky cone appears to rise first as a sort of cushion beneath the thorn. In the earliest stage of its growth it is assisted by a lysigenous gland, which is found at its base. The tissue of this gland is differentiated by the formation of a small area of cells with granular contents, around which the neighboring cells become arranged concentrically, and the number of cells between the vascular ring and the epidermis becomes increased. In a more advanced stage, the cells on each side of the gland become collenchymatous, and the thorn becomes prominent, its cells elongating in the direction of its length. The cells outside the collenchyma then divide and form a meristematic layer at the base of the thorn, the cells nearer its apex becoming rapidly elongated, pitted and thick-walled. The change takes place more rapidly at the surface of the thorn, so that a hard tissue is formed around a softer core.

In the autumn the meristematic cells become sharply marked off from the underlying cells of the cortex, and are much shorter and more closely packed than before, assuming and retaining a brick-shaped character, rapidly taking the appearance of corky tissue, and exhibiting rings of growth in the stem of *Pinus*. By the rapid increase of growth of the lower part of the thorn, after the capacity for growth in the epidermal cells has diminished, the tissues around the base of the thorn are ruptured by the tension, and the corky cushion of the thorn becomes evident. The hardened or upper portion of the thorn soon shows at its base a line of separation, caused by a difference of form and the manner of thickening of the cells in its upper and lower part. A split across the top of the cushion and between it and the base of the spiny portion is thus formed. The latter ultimately separates from its corky base and leaves a scar, or causes a truncated appearance on the top of the corky cushion. In rare cases the spiny portion or part of it may still be seen adhering to the top of the corky cushion. Mr. Barber appends to his paper a list of plants, the thorns of which have basal cork formation. This list includes plants belonging to the *Malvaceæ*, *Rutaceæ*, *Simarubeæ*. *Rhamnaceæ*, *Leguminosæ*, *Rosaceæ*, *Araliaceæ*, *Cactaceæ*, and *Euphorbiaceæ*.—*Phar. Jour. and Trans.*, Aug. 6, 1892, p. 108.

MISCELLANY.

At the recent meeting of the American Orthopedic Association the following officers were elected to serve for the ensuing year: President—Dr. A. J. Steele, St. Louis; Vice-Presidents—Dr. Samuel Ketch, New York; Dr. Arthur J. Gillette, St. Paul; Treasurer—Dr. A. B. Judson, New York; Secretary—Dr. John Ridlon, 34 Washington St., Chicago.

Dr. W. S. Christopher, Professor of Diseases of Children in the Chicago Policlinic, has also been appointed Professor of Diseases of Children in the College of Physicians and Surgeons of Chicago.

Dr. W. C. Wile, editor of the *New England Medical Monthly*, was elected Surgeon-General of the Grand Army of the Republic at the annual encampment of that organization in Washington in September.

Meeting of International Medical Congress (American Public Health Association), in the City of Mexico, November 29th and 30th and December 1st and 2nd, 1892. For the convenience of delegates, and all physicians with their families, who desire to attend this meeting, an elegant Pullman car will leave Chicago November 19th. Short stops will be made at all points of interest between Chicago and the City of Mexico. For further information, maps, time tables, etc., address John E. Ennis, D. P. A., Mo. Pac. Ry., 199 Clark street, Chicago, Ill.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from September 24, 1892, to September 30, 1892.

Capt. William Stephenson, Asst. Surgeon U. S. A., is relieved from duty at Ft. Porter, N. Y., and ordered to Boise Bks., Idaho.

Capt. Eugene L. Swift, Asst. Surgeon U. S. A., promoted Captain, to date from August 12, 1892.

First Lieut. S. R. Dunlop, Asst. Surgeon U. S. A., is granted leave of absence for one month, with permission to apply for an extension of one month. Par. 2, S. O. 99, Hdqrs. Dept. of Texas, San Antonio, Tex., September 20, 1892.

First Lieut. Wm. F. Lippit, Asst. Surgeon, will proceed from Camp Eagle Pass to Camp Pena Colorado, Tex., and report to the commanding officer for temporary duty. Par. 3, S. O. 29, Hdqrs. Dept. of Texas, San Antonio, Texas, September 20, 1892.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Five Weeks Ending September 24, 1892.

Surgeon W. H. H. Hutton, to proceed to Cape Charles Quarantine for special duty. August 27, 1892. To proceed to Sandy Hook, N. J., for special duty, September 10, 1892. Relieved September 16, 1892.

Surgeon John B. Hamilton, to report in Washington, D. C., for special temporary duty. September 2, 1892.

Surgeon H. W. Sawtelle, detached for special duty as quarantine inspector, Canadian frontier, September 5, 1892. To proceed to Sandy Hook, N. J., for special duty. September 16, 1892.

Surgeon G. W. Stoner, detailed for special duty as quarantine inspector, Michigan ports. September 3, 1892.

Surgeon F. W. Mead, to proceed to Baltimore, Md., on special duty. September 24, 1892.

P. A. Surgeon C. E. Banks, to proceed to Washington, D. C., for special duty, August 26, 1892. To rejoin station September 8, 1892. To proceed to Washington. D. C., for special duty, September 22, 1892.

P. A. Surgeon S. C. Devan, to proceed to Delaware Breakwater Quarantine for special duty, August 28, 1892.

P. A. Surgeon P. C. Kalloch, to proceed to Portland, Me., for temporary duty, August 26, 1892. Detailed for special duty as quarantine inspector Maine ports, September 8, 1892. To proceed to Washington, D. C., for special duty, September 15, 1892. To proceed to Portland, Me., for temporary duty. September 22, 1892.

P. A. Surgeon Eugene Wasdin, to proceed to Sandy Hook, N. J., for special duty, September 13, 1892.

P. A. Surgeon J H. White, to proceed to Way Cross, Ga., for special duty. September 19, 1892.

P. A. Surgeon J. J. Kinyoun, to proceed to Baltimore, Md., on special duty, August 27, 1892. To proceed to Philadelphia, Pa., on special duty, September 1892. To proceed to New York, N. Y., on special duty. September 21, 1892.

P. A. Surgeon J. O. Cobb, to proceed to Sandy Hook, N. J., for special duty. September 19, 1892.

P. A. Surgeon J. B. Stoner, to proceed to Sandy Hook, N. J., for special duty. September 13, 1892.

P. A. Surgeon C. P. Wertenbaker, to rejoin station (Chicago), August 28, 1892.

Asst. Surgeon J. C. Perry, to proceed to Norfolk, Va., for temporary duty, August 27, 1892. To proceed to Cape Charles Quarantine for special duty. September 8, 1892.

Asst. Surgeon W. G. Stimpson, to proceed to Delaware Breakwater Quarantine for special duty. September 2, 1892.

Asst. Surgeon A. J. Rosenau, to proceed to Cape Charles Quarantine for special duty. September 10, 1892.

Asst. Surgeon L. E. Cofer, granted leave of absence for sixty days on account of sickness. September 2, 1892.

Asst. Surgeon W. J. S. Stewart, to proceed to Charleston, S. C., for temporary duty, August 26, 1892. To rejoin station (New York), September 2, 1892.

Asst. Surgeon Edgar Strayer, assigned to temporary duty at Boston, Mass., September 6, 1892.

PROMOTIONS.

Geddings, H. D., commissioned as P. A. Surgeon September 2, 1892.

Wertenbaker, C. P., commissioned as P. A. Surgeon September 2, 1892.

APPOINTMENT.

Strayer, Edgar, M.D., of Pennsylvania, commissioned as Asst. Surgeon September 2, 1892.

ORIGINAL ARTICLES.

KUMYSS—ITS VALUE AS A FOOD AND RECONSTRUCTIVE.

Read in the Section of Physiology and Dietetics, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY J. MOUNT BLEYER, M.D.,
SURGEON TO THE NEW YORK NOSE AND THROAT INFIRMARY, AND EDITOR ELECTRICAL REVIEW.

My object in bringing this paper before you, is to call your attention to the valuable dietetic properties of kumyss and to give you the results of my experience with a new kumyss preparation, called "Kumyssgen" (a kumyss in a dry form).

HISTORICAL SKETCH.

From time immemorial the Nomad tribes of Southern and Eastern Russia and Central Asia, have prepared and used kumyss. Herodotus gives an account of it as used by the Scythians, Virgil sings of a tribe who drank it. Perhaps, the first mention of it by name, may be found in "Ipatof Annals" published at St. Petersburg in 1871. In 1182, Prince Igor Seversky was taken prisoner by the Polobtsy and the captors got so drunk on kumyss that they allowed their prisoner to escape. The old monk and traveller Wm. de Rubruquis, in the thirteenth century, was the first one who wrote a distinct and admirable account about kumyss and its action, its taste and preparation. He says: "The same evening the guide who conducted us, gave us some *cosmos* (which he call the drink). After I had drank it, I sweat most extremely from the dread and novelty, because I never drank it before. Notwithstanding I thought it very savory and indeed it was." And in another part of his travels, he thus refers to it: "Then they, the Tartars, tasted it and being pretty sharp, they drank it, for it biteth a man's tongue like wine of raspberries, when it is drunk. After a man has taken a draught thereof, it leaveth behind it a taste like that of almond milk, and it maketh one's inside feel very comfortable, it also intoxicates weak heads." The next writer to refer to kumyss, is Marco Polo, the Venetian, in his "De Regionibus Orientals." "Their drink is mare's milk prepared in such a way, that you would take it for a white wine, and a right good drink it is,called by them '*Kemiz*'."

For nearly 500 years after these old travelers wrote, no mention of kumyss, so far as I am aware, is to be met with in European literature, and it is only towards the end of the eigthteenth century, that it is again brought into notice. Thus Strahlenberg was the first, after de Rubruguis, to give a description of the preparations of kumyss, but his method, although borrowed from and said to have practiced by the Kalmucks, seems to have been unsuccessful. Neumann, a German, and Voltenlau, a Dutch chemist, proved equally unsuccessful in their attempts to explain the nature and causes of fermentation in mare's milk. Pollas while mentioning kumyss, in his travels, also states that the Tartars, during winter,when mare's milk fails them,prepare a wine from cow's milk. Gmelin gives an account of the distillation by the Nomads of a spirit from milk, while Oxeretkowsky in 1778, sent a graduation thesis to the Academy at St. Petersburg. (These last two writers wrote only about the spirit obtained from kumyss, and not about kumyss itself.) All these travelers and authors spoken of, considered kumyss to be simply the intoxicating beverage of said Nomad tribes. No one appears to have been impressed by its remarkable nutritive qualities, since no one seems to have regarded it in the light of a food. The credit of being the first to estimate the importance of kumyss as an article of diet, and of discovering its uses, as a therapeutic remedy, belongs to Dr. John Grieve, a surgeon, one of the many Scotchman who have, from time to time entered the Russian service, and who in 1784, wrote a communication to the Royal Society of Edenburgh, entitled, "An account of the method of making a wine, called by the Tartars, kumyss, with observations on its usage in medicine." And he thought that "With the superaddition of a fermented spirit, it might be of essential service, in all those disorders where the body is defective either in nourishment or strength." And he further proved the benefit of the milk wine on three patients, two of whom were consumptives, sending them to the steppes among the Tartars, from where they returned stout and in perfect health. After the return of these first patients, sent to Tartary, Grieve commenced making kumyss himself.

At the beginning of the present century Dr. Haeberlin gave an excellent description of kumyss; he being a consumptive, tried its therapeutical effects on himself for 13 long years. From the year 1811, when Haeberlin's communication was posthumously published, until the year 1857, several treatises on kumyss are to be found scattered through various Russian and German periodicals, lay and medical.

But in 1858, Dr. Postikof started an establishment for the cure of diseases, by fermented mare's milk, at Samara, in Eastern Russia, and a similar establishment about 45 miles distant, was started by the late Dr. Tchembulatof, both of which have been extremely well patronized by patients from all over the world. So successful were they, that the Russian government, in 1870, started a place of their own for the cure of sick soldiers, belonging to the Kazan district. Here were provided 120 beds, and at this little hospital, the surgeons began their experiments with the kumyss cure, which proved thoroughly successful. Various diseases were treated and the hospital was still in existence after ten years' trial.

The first persons to test the value of kumyss in hospital practice, were Dr. Neftel, who in 1859 treated 15 soldiers with it, in the Orenborg Military Hospital, and Dr. Zéland, who in 1861 accompanied a party of phthisical soldiers sent by the Russian War Office, to drink fermented mare's milk in the Bashir Steppes. Both of these surgeons spoke highly of kumyss, in the admirable essays published by them on the subject.

In ending this imperfect sketch of the history of kumyss, a few words in regard to its literature, during the last few years, may not be out of place. From 1858 to the present day, several excellent pamphlets and articles were published on kumyss, embodying the experience of those who had been in the steppes, and who had carefully and dispassionately investigated its action in disease, and it is a fact that since John Grieve's time, not a single medical author, practically acquainted with kumyss, has failed to give it full praise, as the best known remedy and reconstructive agent, in all wasting diseases. The writings of Drs. Grieve, Haeberlin, Homenko, Dahl, Maydell, Ucke, Stahlberg, etc., etc., bear witness to what has been stated, and display in their praises of kumyss, a unanimity of opinion quite exceptional in the history of therapeutic remedies. In a few rare instances, where we find kumyss disparagingly spoken of, it is by authors who had no practical knowledge of its uses.

KUMYSS PREPARATIONS.

The curative properties of mare's milk induced physicians and chemists to try cow's milk, which is so much easier to procure, for making kumyss. It was successfully tried and a new food and drink was given to the civilized world. Dr. Jageliski says, "I consider cow's milk an equally good raw material, if not better than mare's milk for the preparation of kumyss;" while Dr. Landowski regards the richness of cow's milk as advantageous when compared with mare's, to the invalid, who absorbs a larger quantity of nutritive material; then came a preparation, made by fermenting a mixture of cow's and asses milk, which made an excellent substitute for kumyss, and a new name was coined for it, which may be applied to all fermenting milk, "Galazyma,"taken from the Greek. For particulars, I would refer you to a little work, by Dr. B. Schnepp, of Eaux Bonnes, entitled "Traitment efficace par le Galazmye des effections catarrhales, de la phthsic et des consumptions en general, Paris, 1865."

I will not dwell on the methods of the manufacture of kumyss, as it can now readily be obtained prepared for use; in fact, I would advise against its preparation in the household, or by the physician. The operation is a delicate one, it requires special knowledge and appliances for regulating temperature, etc. The new preparation, "kumyssgen," being in the form of a dry powder, can be sent everywhere, and the preparation of an excellent kumyss from it is a very simple matter.

The milk of various animals is made use of, besides that of the cow, namely: the goat, the ass, sheep, camel and mare. Milk is used as it is drawn, or in the form of whey or curdled. Ghee is a favorite beverage throughout all India. It is a stale butter, clarified by boiling and straining. When it is set aside to cool, it remains in a semi-liquid or oily state, and is used as a drink and in cooking by the natives. In milk-beer, milk is substituted for water. Kef-is a kind of effervescing fermented milk, resembling kumyss, which is made at Samara. Yamanet is a favorite drink in Constantinople, made by curdling milk in a peculiar manner. Syra is a sour whey used as a drink like small beer in Norway and Iceland. Aizen and liban, both forms of kumyss, are made one by the Tartars, the other by the Arabs. Kefir is another fermented beverage, prepared in the mountains of the Caucasus from cow's milk. This fermentation process is brought about by a micro-organism, the Dispora Caucausica, which is added to the milk; it possesses the property of converting the milk sugar into alcohol, carbonic acid and lactic acid.

WHAT KUMYSS IS.

We know that kumyss is a highly effervescent, slightly acidulous beverage, made from milk by a peculiar process of fermentation. It contains the casein, the most nutritious element of milk, in a form in which it can be much more readily digested and assimilated.

The principal changes which milk undergoes, when converted into kumyss, are: the milk sugar is partly converted into lactic acid, carbonic acid and alcohol, the albuminoids are partially peptonized, and the remainder separated into such a finely divided state that the digestive fluids can readily act on them. As the above changes are constantly going on in kumyss, we can readily see that it is not at all stable, that its composition is constantly changing.

While in the first stage, when still somewhat sweet and only gently effervescent, it is called *mild kumyss*, similar to kumyss made from kumyssgen, when freshly prepared. This, in the course of a few days, passes into the *strong kumyss*, decidedly acid and highly effervescent. While in the intermediate state it is called *medium kumyss*. All these conditions are under perfect control by the use of kumyssgen.

Kumyss when taken in large doses, should not be administered too cold. Except in cases of severe and uncontrollable vomiting, it should be given with the chill off, and will then be found very easy to digest. This point I want to impress on you, particularly when used in pulmonary phthisis, where the consumption of large quantities of kumyss is required, and where the nearer the temperature of the ingested fluid approaches that of the blood, the sooner and easier will it be absorbed and digested. A temperature of about 60° Fahrenheit is found to be the best.

The next question is, in what quantities shall kumyss be taken? The first precaution to be observed is that the quantity should never exceed what the invalid's stomach can easily digest, and will also depend upon the disease for which kumyss has been prescribed. As a food, any quantity can be taken by a healthy individual.

Regarding the physiological action of kumyss and its many therapeutical applications, I must refer you to the literature on the subject, as the allotted time for the reading of this paper is limited.

Some of the therapeutical applications, both as a special addition to foods and as a reconstructive, which I have made with kumyssgen. We know that there are diets suited to every age, to every climate, to every species of work, physical and mental; there are diets by which diseases may be prevented and cured; diets beneficial to some constitutions and injurious to others; diets which make the skin glossy, the frame vigorous and the spirit joyous; others which mar the face with wrinkles, speckle the body with eruptions, and make the form sallow, lean and prematurely old.

When by successive researches, the science of diet, feeding and administration of proper reconstructives to patients, is better understood, without doubt a school of physicians will arise, discarding all drugs and treating disease by forbidding certain foods and by surfeiting with others; if indeed at the present time there is not, in the highest representatives of medicine, the nucleus of the future school of dietetics already formed.

Invalids! What thoughts does that word call into being; what pictures does the imagination construct. The whole world seems full of invalids; beings whose life is a burden to them, who would give their wealth to be relieved of their wretchedness, who would barter their knowledge and fame for the careless life of the healthy man.

We meet them in a dreary procession, here and across the continent of Europe, scattered up and down the sunny shores of the Mediterranean, steaming across the sea in pursuit of rest, camping on lonely spots to cheat their pain, all up and down the world, among the haunts of men, life taking its sad tinge from their heritage of weakness.

There are invalids who are such because they do not have enough food; there are those who are such because they have too much food; there are invalids who have made themselves such by improper diet; and there are invalids who are invalids because they will not eat proper food.

There is no doubt that improper food is often the cause of our ills and certain maladies—that much abused member of our body, the stomach, is often answerable for ill-temper, discontent, fretfulness, caprice and ennui, and yet if we listen to its admonitions, and heed its teachings, we should enjoy more peace and find more happiness in our lives.

The success of halt the water cures and health resorts is based on this fact, for they associate with their strictly medical treatment a strict dietetic regimen, plain, wholesome and temperate, and which is insisted on as part of the cure, knowing that the over-eating and drinking, during the city season, must be combated with the moderation of the holiday season. It is a very rational mode of treatment, and is the only one that will restore the balance. Far better would it be, if the need for cure did not exist, but such self-denial is too much to look for, in these enervating days.

In an article published by me, in the *Journal of Baneology and Dictary*, of March, 1892, entitled "Diet, Digestion and the Voice, etc.," I had occasion to thoroughly discuss this subject, giving my several years' experience in the treatment of the diseases of vocal organs in singers, actors, clergymen, lawyers and others, observing that diet played a chief part in their successful treatment. I have also spoken in detail in this article of a diet (a modification of the true vegetarian system), called by me "modified vegetarian," one which I adopt for various reasons explained therein. I prescribe this mode of living in all diseases of the nose, throat and the ear, and in all catarrhal forms of chest diseases, either simple or complicated, with Bright's or other forms of kidney diseases, in rheumatism, gout, dyspepsia, and stomach disorders of all kinds, in nervous diseases and in all degrees of alcoholism.

My modification of the mixed vegetarian system, consists in the utility of fats as an economiser of albuminoids, and I must say that a vegetarian diet, in which animal and vegetable fats enter freely, is a very much more complete food and likely to be very much more satisfactory, than one from which all animal fats, like butter, cream, milk and kumyss are excluded. Indeed vegetarianism with liberal allowance of fats of all kinds, has in my experience given by far the most satisfactory results, in such cases as gout, rheumatism and indeed in all dyspeptic disorders.

From my experience of several years' employment of this system in my practice, I do not consider that by this means we reduce the albuminoids too much. I can commend this modified form of vegetarian system, though its adoption must not be undertaken too suddenly, and must be done under the supervision of a physician.

When prescribing such a diet, I supply the albuminoids by using kumyssgen or kumyss and lean meats of all kinds, etc. The kumyss, I allow my patients to partake of as much as they desire to drink.

We know that most professional people, whom we are called upon to treat for affections of the nose, throat, etc., are accustomed to high living. We therefore often find in this class of people, old cases of dyspepsia, as well as an atonic state of the small and large intestines resulting therefrom, and I find that such cases are readily relieved by kumyss, with a modified diet. I have had patients whose digestion had for years been accompanied by extreme uneasiness or pain, and who are obliged to confine themselves to the simplest articles of food, which only half nourish their bodies. Soon after being placed on kumyss and a proper diet, the distressing symptoms disappear, their stomach after a time, regaining the power of digesting almost all foods.

In cases of scrofula, syphilis and anæmia where the blood is impoverished or poisoned or the tissues are undergoing rapid waste, there is nothing known that gives so much satisfaction, as kumyss combined with the remedies in use for the treatment of these affections. The combination of iron and kumyss gave me excellent results.

It was found that in all such cases, kumyss produced no specific action, but was simply the most digestable food that could be employed, with the view of improving the quality of the blood, and the nutrition of the body.

In the many operations which we are called upon to perform about the mouth, throat, etc., I know of no better food, that serves to keep the body above par during the healing process, than kumyss given "ad libatum." I find kumyss of special service after the operation of intubation of the larynx. In these cases, I am in the habit, where swallowing is interfered with, of feeding by a stomach tube, and the only food that I found thus far suitable, was kumyss. I would feed the patients on it from three to four times daily, giving the quantity indicated by the age.

In two cases of cancer of the œsophagus, the nutrition of the body was extremely low when the cases came into my hands for treatment, on account of a lack of nutritious food. These cases having the cancerous growth so situated, I intubed the œsophagus and through the opening thus made, kept up the nourishment of these patients by kumyss and a generous diet. Large quantities of kumyss were administered in this way. Their life beyond doubt, was prolonged for eight months, besides relieving them from the agonies of starvation, which is the usual end in such cases. I will cite one more important case from my record book, showing the importance of kumyss as a reconstructive.

A child two years old was suffering from a syphilitic tumor at the base of the interior of the epiglottis; the tumor involved the vault of the larynx, which necessitated a dangerous operation at that age. I intubed the child and by means of the stomach pump, fed it on kumyss for three months, until the action of the remedies employed for the treatment of this tumor, resulted in diminishing its size. The child recovered without much loss of weight.

Many other similar cases thus treated with kumyss, I could cite, and I would advise you all to give this valuable food a thorough trial. I can highly recommend its use, in all branches of medicine, as well as in my special cases. For additional points connected with special application of "diet" dietetics for all voice users, I must refer to my article cited above.

In conclusion I would say, that I have substituted kumyss, made from kumyssgen (the new dry form of kumyss) in all cases where I formerly employed liquid kumyss, and find it much superior in many respects, both in regard to convenience of handling and in the results obtained. It is uniform in composition and I find most patients will take it readily, which is not the case with the liquid kumyss.

LARYNGEAL TUBERCLE AND TUBERCULIN.

Read in the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY A. J. ERWIN, M.D.,
OF MANSFIELD, OHIO.

It is not the object of this paper to enter upon a general study of the treatment of laryngeal tubercle with tuberculin, or to summarize the published experience of others, but merely to give you a brief account of a few cases from my own clinic, and to make a few inferences from the same. During the past year I examined sixty-three cases of tuberculosis of the respiratory organs, and treated twenty-six of them with tuberculin. Of these twenty-six seven had disease of the larynx in addition to the lung disease, which was well-marked in each case, and in no case was there any indication of either inherited or acquired syphilis, viz.:

Case 1.—Wm. Brintenbucher, æt. 20; Londonville, Ohio. Cough began about January 1, 1891; had hæmorrhages April 15 and 16; fever and night-sweats daily; decreased in weight 20 pounds; consumption hereditary on both sides of family.

April 23, 1891, 4 P.M.—*Pulse,* 132; *respiration,* 30; *temperature,* 102. Cough frequent, some expectoration containing bacilli, râles and obstruction in the apex of the left lung, an ulcer on inner surface of left arytenoid cartilage, deep, and a quarter of an inch in diameter. Also a solid tubercle an eighth of an inch in diameter on the first trachial ring.

I treated him exclusively with tuberculin from April 23 to August 15, in all 54 injections from 1-20 to 1. minim each. The solid tubercle and the râles had entirely disappeared by May 20, but the ulcer on the arytenoid did not close until about the first of August. Some thickening remained for two months later, by which time his cough and expectoration had ceased, and he had increased twenty-nine pounds in weight. Up to this date there has not been any return of the disease in his throat, but since April first his lungs show evidence of increasing tubercularization. He has not returned for treatment.

Case 2.—Mrs. Jacob Miller, æt. 23; Mansfield, Ohio. Began to cough and have fever and night sweats in December, 1889; has had an occasional small hæmorrhage; appetite and digestion good; no loss of weight, consumption hereditary on one side.

March 28, 1891, 3 P.M.—Pulse, 100; respiration, 24; temperature, 101. Râles in apices of lungs, cough frequent. Free expectoration containing bacilli, anæmic, fever and sweats daily; tuberculous ulcer covering the inner surface of left arytenoid cartilage. She received 45 injections of tuberculin between March 28, and the following July 1, without producing any change in either lungs or throat for better or worse. She died of lung disease eight months later.

Case 3.—Mrs. George McMullen, æt. 25; Mansfield, Ohio. Cough and fever began December, 1890; has had two slight hæmorrhages; has decreased 20 pounds in weight; lung disease hereditary on both sides of family.

May 13, 1891, 4 P.M.—Pulse, 92; respiration, 22; temperature, 100. Râles throughout left lung; free expectoration. Sputum contains bacilli, cough frequent; left arytenoid a little thickened, not ulcerated; appetite and digestion poor. Began injections of tuberculin May 14, 1891. By June 1, entire anterior surface of left arytenoid had ulcerated with increased thickening of the cartilage. Treatment continued to July 21, in all 32 injections. When discontinued, the arytenoid thickening had considerably diminished, the ulcer was about half the former size. Left lung unchanged. Appetite and digestion improved. The fever and sweats had ceased by the middle of June; her weight had increased 5 pounds. There was no return of fever or sweating, nor increase of the lung, or laryngeal disease until March, last, since which date there has been a gradual increase of the lung and laryngeal lesions. The treatment has not been renewed.

Case 4.—Wm. Masky, æt. 30; Mansfield, Ohio. Cough, fever and sweats began with the grip November, 1889; has lost 27 pounds in weight; lung disease hereditary on one side of family.

May 18, 1891, 5 P.M.—Pulse, 120; respiration, 24; temperature, 101. Upper lobe of each lung obstructed; murmur very deficient; no râles; frequent cough; no expectoration; mucous from throat contains bacilli; anæmic and weakened. Larynx and trachia covered with miliary tubercles. I treated him with tuberculin from May 18 to July 1, without making any improvement on either throat or lungs. He died of pulmonary hæmorrhage three months later.

Case 5.—J. D. Tipton, æt. 26; Ashland, Ohio. Cough and fever began September. 1890; had frequent profuse hæmorrhages in April and May. Consumption hereditary on both sides of family.

May 25, 1891, 3 P.M.—Pulse, 128; respiration, 32; temperature 102. Obstruction and râles throughout the right lung, and in apex of left. Cough frequent, expectoration large; sputum contained bacilli. No disease of larynx. Began tuberculin injections May 26, 1891, which were continued daily at first, and semi-weekly afterwards to Aug. 6, from one-tenth to one minim each. About July 4 an ulcer opened on the right ary-epiglottic fold, and one on the inner surface of the left arytenoid, with considerable thickening. Last examination, Sept. 7, showed no improvement in either throat or lungs. Died Jan. 1, 1892.

Cass 6.—Frank Stevens, æt. 27; Carey, O. Cough and fever began spring of 1890; had several large hæmorrhages in June, 1891; lung disease not hereditary, although two brothers and sisters died of it.

Sept. 21, 1891, 3 P.M.—Pulse, 120; respiration, 24; temperature, 100. Râles and obstruction throughout right lung; superior lobe of left obstructed; miliary tuberculosis covering pharynx and larynx; free expectoration containing bacilli. Received tuberculin treatment for one month, in all 20 injections, without any improvement of throat or lungs. Died a few weeks later.

Case 7.—Mrs. A. Voeglir, æt. 28; Mansfield, Ohio. Cough, fever and night sweats began July, 1890; has lost 26 pounds in weight. No hæmorrhages; very weak and anæmic. Father and sisters died of consumption.

May 7, 1891, 4 P.M.—Pulse, 130; respiration, 30; temperature, 103. Obstruction and râles in apex of each lung, left arytenoid double as thick as the right, with deep ulcer covering anterior surface, from which pain extends to left ear; cough frequent, expectoration moderate; bacilli in sputum. Began treatment with tuberculin May 8, 1891. For the first month daily injections, beginning with one-tenth and reaching two minims each. By July 1 the obstruction and râles had disappeared from the lungs. September 5, the thickening had left the arytenoid, but the ulcer did not entirely heal until about Nov. 1, leaving some deformity of the cartilage. She passed the winter without return of fever, sweats or expectoration, and scarcely any cough, with a good appetite and good digestion, and fifteen pounds of increase of weight. In March last, she had an attack of the grip, which developed some râles in apex of right lung, and some infiltration of the previously diseased left arytenoid and fold extending to the epiglottis and slight fever. She returned to the tuberculin treatment, having an injection of from one to two minims twice per week. After about half a dozen injections the laryngeal infiltration disappeared without ulcerating, and the râles ceased in the lung a week or two later. She has now scarcely any cough or expectoration, and no bacilli with sputum. No fever, and fair health. Since September first, 1892, some disease in apices of lungs, with cough and expectoration, which is again improving under tuberculin injections, but no return of disease of larynx.

I believe that had Mr. Brintenbucher and Mrs. McMullen returned to the tuberculin treatment when the disease reappeared they would again have been relieved as readily as was Mrs. Voeglir.

In addition to these seven cases treated, I examined five others last summer who did not take the tuberculin but continued other treatment. Every one of them have since died. The inferences that might be drawn from this limited experience are, viz.:

1. Tuberculin will cure some cases of tubercular laryngitis, and will generally stop its progress.
2. The treatment must be continued much longer than is generally practiced to affect a cure.
3. Should there be subsequent renewal of the disease, the treatment should be repeated without delay.
4. It is only in the earlier stage of tuberculosis that the tuberculin treatment is likely to be successful.
5. Considered in connection with my experience in the treatment of lung disease with tuberculin, laryngeal tubercle is less amenable to the tuberculin treatment than is phthisis pulmonalis.

In answer to the inquiry as to the results of the tuberculin treatment in pulmonary tubercle, I would say, that of the twenty-six cases treated, more than one-half were too far advanced to expect any benefit, and yet of the whole number treated one year ago, five are now in good health (June 1, 1892), without any sign or symptom of tuberculosis, four were greatly improved, but relapsed during the past spring; two of them have since died without renewing the treatment, the other two returned to the tuberculin and have again improved and are in fair health. Seventeen were not improved by the treatment. In no case was there any bad effect from the injections. I made in all five hundred and twenty-two injections of tuberculin without causing one abscess, or one case of laryngitis.

THE PHYSIOLOGY AND PATHOLOGY OF THE TONSILS.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY JOHN NORTH, A.M., M.D., PH.C., F.S.SC., LOND.
PROFESSOR OF DISEASES OF THE NOSE, THROAT AND LUNGS, IN THE TOLEDO MEDICAL COLLEGE, TOLEDO, O.

Lennox Brown says: "Of the primary value of these glands there is considerable doubt, but it is certain that at a very early age, and in the great majority of instances, they exist only to become diseased, so much so that a very eminent physician has stated that were he to play the part of a Frankenstein and endeavor to create a man, he would omit the tonsils."

The term tonsil is applied to the collection of so-called lymphoid tissue known as the faucial tonsil.

The tonsils are situated on each side of the fauces, between the anterior and posterior pillars of the soft palate. Gray says: "They are of a rounded form, and vary considerably in size in different individuals;" he does not give their size. Holden says: "The tonsil consists of an aggregation of muciparous glands." No mention is made of their size. Ellis and Ford say: "This body (the tonsil) is an aggregation of ten or twenty follicular glands, like those over the root of the tongue, and it occupies the interval between the arches of the palate. Its size varies much. Its situation is marked by the presence of small holes in the mucous membrane, without any surface prominence; but when enlarged from disease it projects, diminishing thus the size of the isthmus of the fauces." Ranney says: "The tonsils are small bodies situated between the anterior and posterior pillars of the fauces upon either side." Delavan in Satterthwaite says: "The tonsil consists essentially of a reduplication, more or less extensive, of the oral mucous membrane, containing in its folds an abundance of the so-called adenoid tissue." Mackenzie says that the tonsils are generally about as large as a hazel nut, and "can be just seen when the mouth is wide open, projecting into the isthmus faucium." Sajous says: "Each tonsil is about 9 lines long and 6 lines wide, and its thickness is usually so limited in the normal condition as to render its examination very difficult." Rumboldt says: "If they are in a healthy condition they do not project within sight; if they are in sight, then they are in a more or less diseased condition."

Drs. Bosworth, Woolen and others claim that normally there are no tonsils—that the enlargements we call tonsils are in reality abnormal conditions.

Dr. Roe says this in the main is true. Normally the collection of glands at these points are not noticeable on inspection of the throat, and therefore no tonsil appears to exist.

Every rhino-laryngologist knows that less than 50 per cent. of all the throats that he looks into have no tonsils, as we understand the word tonsil, referring to a protruding gland occupying the space between the anterior and posterior pillars. If we were to look into the throats of a large number of people, men, women and children, we would be surprised at the small number of tonsils that we can see, and when we do find them we find them associated with chronic naso-pharyngeal troubles, and not with a healthy naso-pharynx.

Now let us inquire and examine into what we do find between the anterior and posterior pillars of the soft palate. Gray, without saying anything about their size or thickness, says: "Its inner surface presents from twelve to fifteen orifices, leading into small recesses, from which numerous follicles branch out into the substance of the gland. These follicles are lined by a continuation of the mucous membrane of the pharynx, covered with epithelium, their walls being formed by a layer of closed capsules imbedded in the submucous tissue. These capsules are analogous to those of Peyer's glands; they contain a thick grayish secretion." In another place Gray says: "Peyer's glands may be regarded as aggregations of solitary glands." He also describes solitary glands as "small round, whitish bodies, from half a line to a line in diameter, consisting of a closed saccular cavity, having no excretory duct, and contains an opaque white secretion. Their free surface is covered with villi, and each gland is surrounded by openings like those of the follicles of Lieberkühn. Their use is not known." Again: "The simple follicles or crypts of Lieberkühn consist of minute tubular depressions of the mucous membranes, arranged perpendicularly to the surface, upon which they open by small circular apertures." If the capsules of the tonsils are analogous to those of Peyer's glands we would expect to find them of the same size in all cases in health, as we find no variations in size in Peyer's glands, except in disease.

Ellis and Ford say: "In its structure it resembles the follicular glands. In the bottom of the holes or depressions on the surface of the mucous membrane, are small apertures leading into recesses or follicles; these recesses are lined by mucous membrane, and are set around with closed capsules filled with a grayish fluid and contain cells, and bodies like free nuclei. The capsules do not appear to have any apertures." Delavan in Satterthwaite's Histology says: "The minute structure of the adenoid tissue of the tonsil does not differ from that of other follicular glands (those of the intestines, etc.)."

In the healthy condition the space between the anterior and posterior pillars is an inverted trouth; if we place our fingers in it without applying pressure we feel a smooth surface, but if we apply a little pressure we find a thickened condition of the mucous membrane. If we produce a contraction of the superior constrictor muscle as in gagging, we find the muscle pressing out this thickened membrane, and we feel and see a projection filling up the space between the pillars. Now the question arises, what does this thickened condition of the mucous membrane consist of? I will not take up your time with the anatomy and histology of mucous membrane, as you are all familiar with it. Mucous membrane is described as composed of three layers:

First. A superficial layer, composed of epithelial cells.

Second. The mucus proper, a layer composed of white fibrous and yellow connective elastic tissue, embracing within their meshes blood-vessels, smooth muscular fibers, different varieties of small glands, and presenting minute processes or villi.

Third. An external layer of loose connective tissue, the submucous cellular tissue.

The chart will show these three layers. You will also notice the presence of simple and compound follicular glands. As to the function of the epithelial cells, I can do no better than to quote Bosworth: "We find the mucous membrane covered with epithelial cells of various character and arranged in various ways, according to the locality and special function which it subserves: the object of the epithelial cells being merely the secretion of mucus. In these tissues, we may regard each individual cell as a typical gland, displayed over the surface of the mucous membrane, whose object is to keep the membrane softened and moistened. In fact, nature endows the membrane in this manner with its own lubricating apparatus. It is found, however, that epithelial cells simply displayed in layers on an unbroken surface are unequal to the demand. In other words, distributed in this manner, they are not equal to supplying a sufficient quantity of mucus for lubricating the passages. To remedy this deficiency, nature resorts to a very simple device for extending the secreting surface. This consists in folding the membrane upon itself, as it were, or in other words, bending it down into the tissues and back again, to form a small flask-like cavity which is called a follicular gland. In other cases, instead of forming a straight fold, the pouch-like cavity of the simple follicle is folded on itself a number of times, forming a group of small flask-like pouches, as it were, which uniting, open upon the surface by a single orifice, thus constituting what is known as a racemose gland. The arrangement of glands and follicles in the mucous membrane, therefore, I take it are for the purpose of enlarging the surface over which the epithelial cells may be distributed, and therefore increasing the secreting power of the membrane, in order that its surface shall be constantly supplied with an abundant quantity of mucus, the normal lubricant of the membrane."

In what is known as the faucial tonsil we have reduplications of the mucous membrane making from twelve to sixteen or even twenty of these follicles, the orifices giving us the crypts of the tonsil. This aggregation of twelve to sixteen follicles is what we call the tonsil. Is it a gland or a collection of glands?

The principal function of this aggregation of follicles in this inverted pouch between the anterior and posterior pillars of the soft palate is to lubricate the bolus of food in its passage to the stomach. In the act of deglutition the contraction of the superior constrictor and palato-glossus muscles presses upon the tonsil, and forces out the accumulated mucus from its numerous follicles.

Other functions are attributed to the tonsil in addition to that as a lubricator of food. Almost every one has a favorite theory in regard to the function of the tonsils. Some of them are hardly entitled to the dignity of a theory, but are merely hypotheses. Some of the theories should receive some attention. One strongly advocated by Dr. Rice is that the tonsil was a blood elaborating organ. This can hardly be borne out by the facts when we more thoroughly examine the case.

In order to determine the relations of enlarged tonsils in children to their general physical development, Dr. Upsenski examined a number of children between the ages of 10 and 14. He found fifty-two cases in which enlargement had taken place. Of these twenty were deficient as to height, weight and circumference of the chest for their respective ages. A few were myopic; thirty-seven lacked acuteness of hearing; most of them were anæmic, with weak and hoarse voice. Breathing through the nose was difficult, and in most of the cases obstructed. With the tonsillar enlargement there was also granular or atrophic pharyngitis in almost every case, and in many there was swelling of the glands of the cervical and submaxillary region. I have never met with a case of enlarged tonsils in which the patient was not better physically after their removal. In cases where the tonsil is normal in size; that is, does not fill up the space between the pillars, and in cases where they have been removed, we do not find deficient elaboration of blood, but the reverse is usually the case.

Others claim that the tonsil is a "leucocyte manufactory," and that on this account the tonsils act as sentinels, or as it has been expressed, act as guard-houses and send out squads of sanitary police, in the form of phagocytes, that stand guard at the entrance of the follicles to catch and destroy any germ that might attempt to enter the tonsil, or even pass through the isthmus of the fauces. It may be true that the germs of disease may be destroyed when they lodge upon the surface of the normal tonsils, but when we have any enlargement of them, we find the orifice of the follicles wide open, and the germs enter and find an excellent media for development. It is a very nice theory, and one that seems to please the public. They have vivid pictures drawn in their minds of the phagocytes setting upon tonsils, ready to destroy any and all the germs that attempt to enter the system through the mouth. The public are not alone in this, but even some physicians share the same opinion, and think that the tonsils are placed in the fauces for some use, and the larger they are the more capable they are of performing their functions, and that they should never be disturbed until they reach such size as to interfere with respiration, and then recommend that a little of the surface be clipped, but that care be taken not to remove too much, as it would interfere with their proper function—which is true in enlarged tonsils, to a certain extent, for they would lose their function as germ and poison absorbers, which seems to be about the only function that enlarged tonsils possess.

In prehistoric times, and in some of the savage tribes at present, that depend upon dry nuts and roots for food, something was required to lubricate the bolus of food. But with our modern cooks and method of preparing food, a lubricant is not necessary.

Time will not permit me to take up and consider all the theories that have been advanced in regard to the physiological functions of the tonsils. Most of them are only theories and a theory at best is only scientific guessing.

When we come to consider the pathology of the tonsils we find that we are about as ignorant of its pathology as we are of its physiology. Of its pathological anatomy we know considerable, but of its true pathology, that is, the physiology of its diseased condition, we know but little. We can never know the pathology of any organ till we first know its physiology. The surgeon might just as well attempt to understand surgery without a knowledge of anatomy.

Physiology is the language of histology, while pathology is the language of pathological anatomy, or diseased histology. Pathology and pathological anatomy are incorrectly used as synonymous terms by a great many medical writers.

It is very questionable whether the tonsils ever become diseased unless there is an underlying dyscrasia or constitutional taint of system, or by the lodgment of some microörganism in the follicles of the membrane.

The contents of the crypts or follicles of the tonsils when in a healthy condition consists of mucus with exfoliated epithelial cells. It is a question whether anything else is found. Cultures made from their contents do not show the presence of any microörganism. When there is enlargement of the tonsils the follicles become larger, and are filled with a yellowish substance composed of fat-molecules, detached pavement-epithelium, lymph-corpuscles, small molecular granules, and cholesterin-crystals, which probably proceed from retained and decomposed epithelial matter, and perhaps from the bursting of the capsules, which have undergone retrograde metamorphosis and fatty degeneration.

Dr. Wright has made a number of cultures from the contents of the crypts, and where they were at all enlarged he found there constantly the staphylococcus aureus or albus.

I have no doubt that this, or other organisms found in the follicles of enlarged tonsils is the cause of follicular tonsillitis. They generate ptomaines or extractive matter that acts as toxic-material. In a large proportion of cases these organisms do not appear to generate much toxic matter, but when the system is subjected to impure air, such as sewer gas, etc., the germ finds an atmosphere that is favorable to its development. They increase very rapidly under these conditions and in their increase, cause a destruction of the tissues, and a retrograde metamorphosis, with generation of toxic matter. The presence of impure air alone, without microörganisms will not, in my opinion, give rise to follicular tonsillitis, or any other form of tonsillar inflammation. It is very propable that suppurative tonsillitis is only produced by a microörganism, not necessarily a single germ, or one variety of germs in every case. Persons with healthy tonsils of normal size very seldom, if ever, have any form of tonsillitis.

If the diphtheritic bacillus come in contact with healthy normal mucous membrane, without diseased follicles, it cannot find lodgment, and does not develop. But if the follicles are diseased and full of degenerated matter, with their orifice wide open, it generally finds lodgment, and finds a good media for development. It is not necessary that it be in the follicles of the faucial tonsils, but in the follicles of any of the so-called tonsillar structure or lymphoid tissue. Under certain conditions the diphtheritic germ may find lodgment in these diseased follicles, and generate sufficient poison to give rise to constitutional symptoms without the appearance of the membrane for some length of time. Or the germ may find lodgment in the follicles outside of the faucial tonsils and the membrane not be observed till it has spread into the field of vision.

When the diphtheritic germ finds lodgment and develops in the follicles of the tonsil, we simply call it diphtheria, if in the pharyngeal tonsil, nasal diphtheria. If in the adenoid tissue at the upper portion of the trachea it is called membranous croup.

There is a dyscrasia or constitutional taint or condition of the system in some patients, which in some cases appears to be hereditary, in which we have an enlarged and diseased condition of all the circle of lymphoid tissue found in the upper respiratory tract. The term "lymphoidism" has been applied to this condition. In this condition we have enlargement of the tonsils and instead of finding the tonsil a blood elaborating organ, we find that it prevents or retards the elaboration of blood; these patients become anæmic. If the enlarged tonsils and other portions of the enlarged lymphoid tissue are removed, the patient improves at once. In some of these cases the tonsil will diminish under the administration of iron, or the iodides; still better when the combinations of iodine and iron are administered.

The constitutional effect of enlarged tonsils are always relieved by the use of iodine or some of the iodides.

Iodine and the soluble iodides are the best germ destroyers and the best destroyer, of the products of germs.

What is the so-called rheumatism of the tonsils? Is it not simply the action of some microbe and its products? Every symptom of it can be explained by germ action. We find that it is only such anti-rheumatic agents are also anti-germ agents that give us our relief in so-called tonsillar rheumatism. I do not believe that the chemical and microscopic examination of the blood, urine and other liquids and solids of the body will justify us in claiming that tonsillitis and rheumatism are one and the same disease. We may have a rheumatism of the tonsils, but not every case of tonsillitis is rheumatic in its origin.

Sokolowski of Poland, in an article on the "Pathological Inflammatory Affections of the Tonsils," speaks of diseased crypts of the tonsils with increased secretion. We mostly meet in the crypts with plugs composed of compact horny epithelial cells, with a small addition of lymphoid cells. It is known that, for the most part, they are situated in the crypts of enlarged tonsils. The author on examining tonsils hardened in alcohol, convinced himself that the walls of the crypts are strewed with small grains sometimes as if with small papillæ, which under the microscope presented themselves as greatly hypertrophied folliculi, growing into the lumen of the crypts, thence the stenosis of the orifice of the crypts and accumulation of the secretion, which remaining a longer time decomposes and iritates the neighboring tissue resulting in catarrh, mostly characterized by proliferation and great disquamation of the epithelium.

We have all met with cases of recurrent inflammation and suppuration of tonsils, where they have been cauterized or shrunken by electricity or the application of caustics, also in cases in which enlarged tonsils have been clipped or partially removed by the knife.

In this class of cases the remaining portion of the tonsil, even if it has contracted so that it cannot be seen by ordinary inspection, gives the patient and physician more trouble than before the removal. If the crypts or follicles are not entirely destroyed or removed, the remaining portion acts as a source of irritation. The secretions are retained and upon the least exposure or irritation the trouble is set up. I find that the only satisfactory method of treatment in these cases is to destroy or remove all the stump and cicitricial tissue. If any is allowed to remain we are apt to have trouble in the future.

In this paper I have avoided the use of the term hypertrophy of the tonsil, but have confined myself to enlargement of the tonsil. I do not believe that we have a true hypertrophy of these organs, as I understand hypertrophy to be a physiological process due to hypernutrition. There is no increase in the relative number of tissue elements. There is simply over-nutrition and consequent overgrowth of existing elements, dependent upon increased supply of nutrient pabulum, but there is no new tissue not normally found in the part that takes on this excessive growth. The tissue is not diseased.

In another form of enlargement called hyperplasia there is no growth of the normal tissue elements. The increase in size depends upon the organization of the products of inflammation thrown out from the vessels in the stage of congestion and exudation.

In still another form of enlargement of an organ we have a combination of both hypertrophy and hyperplasia. In this form we have not only an increase in the normal tissue elements of the part but we also have an increase of the connective tissue elements within the organ, from the deposit of inflammatory products.

In the condition spoken of as hypertrophied tonsils we find not only an increase of the normal elements, but we have an abundance of new tissue formed, as the result of a pathological process. So that we conclude that hypertrophied tonsil, so-called, is not a simple hypertrophy but is both hypertrophy and hyperplasia combined.

In most of our text books when we find a description of the historological structure, a moderately enlarged tonsil is described. When a tonsil becomes enlarged or thickened, so that it can be observed, or feels thicker to the touch than would be produced by the reduplication or aggregation of a number of simple and compound mucous follicles, we have an abnormal product, it becomes a tumor and is a source of irritation.

The following summary of the physiology and pathology of the tonsils is derived from this paper:

That the faucial tonsil is a collection of from twelve to sixteen separate and distinct simple and compound follicles and capsules, found between the anterior and posterior pillars of the fauces.

That simple and compound follicles with their capsules are found in all mucous membrane.

That the mucous follicles are not distinct glands, but are simply a folding or depression in the mucous membrane, for the purpose of increasing the surface of the membrane.

That the epithelial cells of these follicles, are the glands proper that secrete the mucus.

That the epithelial cells lining the follicles do not differ from the epithelial cells upon the smooth surface of the mucous membrane in the same locality.

That the crypts of the tonsils are simply the opening into the follicles, where the mucous membrane reduplicates itself.

That in the healthy condition the space between the anterior and posterior pillars is an inverted trouth.

That the tonsil in health does not protrude but slightly beyond the surface of the membrane.

That where the tonsil protrudes beyond the pillars of the fauces that it is an abnormal condition.

That the principal function of the epithelial cell is to secrete mucus to moisten and lubricate mucous membrane.

That mucous accummulates in the follicles of the membrane, to be used when occasion demands.

That there is no proof that the tonsil is a blood elaborating organ.

That children with enlarged and diseased tonsils are not as well nourished, nor as well developed and healthy, as children with sound tonsils.

That there is not sufficient evidence that the tonsils are "leucocyte manufactories."

That the leucocytes do not reside on the tonsil any more abundantly than upon mucous membrane in other parts of the body.

That enlarged tonsils have the power of absorbing septic poisons and furnish a good media for their development.

That the tonsil is not a gland, but is an aggregation of mucous follicles, with as many openings as there are follicles.

That with our modern methods of cooking and preparing food, there is no well recognized use for the tonsil.

That diseases of the tonsils are generally the result of microörganisms or an underlying dyscrasia or constitutional taint of system.

That in health the follicles contain mucus and exfoliated epithelial cells, and that cultures of the contents are negative.

That in enlarged and diseased tonsils the contents of the follicles are filled with pathological products, the result of retrograde metamorphosis and fatty degeneration. Cultures made from their contents show the presence of microörganisms.

That impure air will not cause tonsillitis if the follicles are in a healthy condition, and there is absence of germs.

That pathogenic germs are not so apt to develop if the follicles are in a healthy condition.

That the condition of general enlargement of lyphoid tissue called "lymphoidism" depends upon a constitutional condition in the majority of cases, and requires constitutional as well as local treatment.

That tonsillitis and other inflammatory diseases of the tonsils are not always of rheumatic origin.

That the anti-rheumatic remedies that relieve this class of troubles, do so on account of their anti-germ properties.

That inflammation of the tonsils may take place in the follicle or in the adenoid tissue.

That in the partial destruction of the tonsils and follicles, we very often have inflammation taking place on account of the closing of the orifices of the remaining portion of the follicles.

That true hypertrophy of the tonsil seldom if ever takes place.

That we often have hyperplasia of the tonsils.

That enlarged tonsils are usually a combination of hypertrophy and hyperplasia.

That every enlarged tonsil is a pathological product, and that it is a tumor.

SOME OF THE ADVANTAGES OF SECTION WORK IN THE AMERICAN MEDICAL ASSOCIATION—ADDRESS OF THE CHAIRMAN.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CHARLES H. BURNETT, A.M., M.D.,
OF PHILADELPHIA, PA.

Permit me to thank you for the honor you have conferred upon me in making me your chairman for this year. I welcome you to this meeting and ask your indulgence in reading you a few thoughts on the advantages of Section work in the American Medical Association.

The importance of the creation of Sections for the consideration and discussion of various branches of medical and surgical science, in the American Medical Association, has not yet been fully appreciated and can never be over estimated. It may be said boldly that the scientific value of the meetings of this Association can be maintained only by the Section-plan as now fully organized. I would even go as far as to say that the continuance of the scientific life of the American Medical Association can be maintained *only* in this way.

Such being the case, more time should be allowed for Section work, and less time taken up by the general meetings of the Association. Let the latter be purely of an executive nature and much shorter than they have been in the past. The various addresses, on medicine, surgery, hygiene, etc., heretofore read at the general meetings of the Association should be read before the correlated Sections. These addresses heretofore read before the Association in full assembly could be converted into Section transactions; let those hear who are specially interested in the subject, but let the other Sections go on with their special work at the same time. This method would save the time of hundreds of busy men, who would come more willingly a long way to attend these meetings, if they knew such a plan, as suggested, would enable them to devote more time and attention to the Section or Sections of their special choice. But men who desire to read and to hear papers on special subjects, will not take the time to write a paper or attend the meetings of the Association, if they fear that the meetings of the Sections will be too hurried to listen to papers, or what is still more important, to discuss them. This plan would divorce all scientific work from the executive sessions of the Association, a disunion in every way desirable.

The members most interested in scientific investigation and its fraternal discussion in the various Sections would find all they desire. While those more interested, perhaps, in the executive and legislative affairs of the Association, would find ample time for their very important labors, untrammeled by any scientific address, or its discussion. Some such plan as this would please all tastes and bring a larger number of physicians to the meetings of the Association, because each member, no matter what his special bent be, would know before he leaves home that he will be able to hear only what he most desires to hear, and what is still more inviting to the average man, that he will obtain a hearing, in his chosen Section.

A simultaneous meeting of Sections and of the Association for general business is greatly to be deprecated, as such a plan would lead to impairment of attendance and activity in the meetings of the general Association and of the Sections. All delegates should attend the general sessions of the Association. Therefore there should be no hindrance to such an attendance by meetings of Sections at the same time. The opportunity offered some years ago by this Association for several thousand American physicians from Maine to Texas and ocean to ocean, to meet annually in Sections, has been embraced in such a way and to such an extent as to justify the request to shorten the general sessions and lengthen the time allotted for the meetings of the Sections.

So far as pertains to the scientific work of this entire Association it matters little who are its president and subordinate officers; it is impossible for them to be bad as long as the membership is good. But it is very important that the Association shall be able to induce the profoundest students of scientific subjects, of value to the medical profession and the community at large, to come to its meetings and lay before it the results of their labors. Such men will come to the meetings if conducted on the Section plan, and they will stay away if they are not so conducted.

The establishment of the Sections as we now have them has prevented the Association from rapid degeneration into a purely social excursion. A further development of the plan, enabling the Sections to have more time and the general meetings of the Association, less time, will make it a scientific medical power in the country and in the world, and draw into its embrace the best workers in our profession throughout the United States. This will enable the Association to keep pace with other organizations which have already made use of the Section-plan of work, with results in the character of their membership and quality of their published transactions, of which we as Americans should be proud, and which we as members of the American Medical Association should endeavor to obtain in our meetings. The American Medical Association will always possess the great advantage in meeting *anually*, thus enabling investigators to lay their results before a scientific body once a year.

So much for the application of the principle of Section work to the Association at large. What shall we say of, and for ourselves? This Section is four years old, having been created in 1888. At the first meeting in Newport thirty-three papers were read, at its second meeting in Nashville, fourteen were read, at its third meeting, a year ago, in Washington only ten papers were read, though more were promised. This falling off was probably due to the illness of the chairman for that year. This year, as we are pleased to see, there are forty-four papers announced on the programme. The American Medical Association is the Charlemagne of the profession of medicine in this country; let this Section cherish the ambition of being its valiant and faithful Orlando.

Having been fortunate enough to succeed in obtaining the creation of Sections, and now having expressed the hope of gaining more time for Section work, by shortening the hours of the general sessions of the Association, it behooves us to go to work in earnest and make the existence of this Section of value to ourselves, and the profession. A direct and quick way of doing this is to prepare a paper, and attend the meeting and read it. The selection of papers deserving publication, their edition, and all matter pertaining to their publication should they increase greatly in number, might be left to a carefully chosen publication-committee. The discussions provoked by the papers read should be carefully reported by a stenographer, as they are generally as valuable as the essays.

Surely there is no channel in this country through which so large a number of physicians interested in Otology, Rhinology and Laryngology, can convey their views and the results of their labors to so large a number of intelligent hearers and readers as through this Section of the American Medical Association. Therefore, whoever is in earnest in his special work and in the desire and intention to communicate the results of his labors and have them discussed, and to learn from the writings and observations of others, should not fail to embrace the chance of doing these offered in this Section. Having obtained such an arena, from the parent Association, pride should prompt us to fill it with able contestants for the prizes sure to be gained by good scientific work. The presentation of good papers before any Section will tend to keep away bad ones. I know of an instance in which a member, not of this Section, once put himself on the programme as prepared to present a paper. When his turn came to read his essay and his name was called, he was absent. In explanation of his failure to appear he said he had heard so many good papers read, superior to his own, that when his turn came he was ashamed to read his essay. Hence one good result of presenting worthy papers is to keep out valueless articles. Men who might have come to palm off poor stuff upon an unorganized assemblage, may remain to learn when they attend a session of a well-organized Section. Thus not only the general average of excellence in the papers emanating from the American Medical Association is elevated, but its function as a teacher of the profession is amplified. Here the rhinologist and laryngologist may become better aurists while the aurist becomes a better rhinologist. Thus our usefulness as practitioners is increased and our patients benefited by our increased knowledge. For in this Section, as in any other, those interested in the same subjects can meet, discuss and learn to know not only one another but one another's ideas. Thus, we can realize the truth of the Chinese saying that "one can learn more of a man's views by half an hour's conversation with him, than by reading *all* his written works."

"Not by the possession of truth, but by the search after it, are the faculties of man enlarged, and in this alone consists his ever growing perfection." Such are the words of Lessing. May we not ponder these words with advantage and apply them to ourselves in this Section? We possess the facts relating to our specialty, of value to ourselves and others, and we are also seeking for more. Let us assemble here, impart to one another what we know and thus aid one another in the search for more truth. This will enlarge our faculties and lead to the general perfection of the Section, so that our individual imperfections shall be cleared away in its ever-growing perfection.

PAPILLOMA OF THE LARYNX.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY ROBERT D. GIBSON, M.D.,

OF YOUNGSTOWN, OHIO.

The frequency with which papilloma of the larynx are met, and the difficulty often experienced in their removal prompts me to bring the subject before this body for consideration.

About 70 per cent. of laryngeal growths are of a papillomatous nature, and experience has shown that they rarely return if thoroughly removed and the stump carefully cauterized.

As to the methods of removal and means of cauterizing the stump, I would ask your attention for a few moments.

Small growths in accessible positions may be grasped with the forceps and removed without difficulty, and the stump may be cauterized with any of the usual chemical caustics; but those partly concealed and the larger growths with broad attachments (sessile) are not readily grasped with the forceps. These are torn off by pieces, and the operation is more or less incomplete, leaving much to be done by subsequent cauterization. For this purpose the chemical caustics are not suitable, for they either do not *penetrate* deep enough, or they must be used to such an extent that they spread beyond the area desired to be cauterized and do damage to the healthy parts.

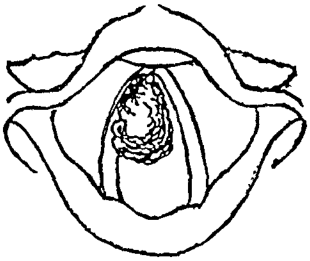
By means of the galvano-cautery these growths may be reached at any point by bending the electrode to the desired shape. Small growths may be destroyed by a single puncture, and large ones by repeating the cauterization from time to time till they are entirely destroyed.

Large growths may be removed *en masse* by means of the galvano-cautery snare; small growths are not easily caught in the loop and are best destroyed by simply puncturing them with the galvano-cautery needle.

The galvano-cautery snare possesses several advantages over the forceps for the removal of large laryngeal growths. Its action is sure, quick, painless and bloodless. The stump is cauterized at the same time the growth is removed. The galvano-cautery outfit for laryngeal work should consist of a one cell storage battery (or a suitable current controller if the street current is employed). Shech's handle, one half doz. electrodes (assorted), canula, fine wire, and connecting cables.

Everything should be in perfect working order before the throat is cocainized, as the effect of the cocaine soon passes off. With a well trained throat to operate on and everything in perfect working order, it is often impossible to reach the exact point desired, or to pass a loop over a tumor and get it properly adjusted, without a considerable loss of time. And my experience has been that when a throat is once irritated by the presence of an instrument it is not so readily controlled again that day.

The following case, of which the accompanying illustration is a faithful drawing, will illustrate the advantage of the cautery snare over the laryngeal forceps.



Laryngoscopic Image.—Papilloma, springing from the anterior two-thirds of the right vocal cord.

Mrs. ——, æt. 27 years, U. S. parentage, otherwise healthy, possessing a full contralto voice, and very fond of music, suddenly lost her voice for singing; she could not sing anything. She thought she had "strained her voice." Months passed along and the voice grew more husky, and finally the trouble began to interfere materially with breathing and conversation. Upon examination a large papilloma was found springing from the anterior two-thirds of the right vocal cord, falling down between the cords. The throat was trained for some months, by passing the forceps down into the larynx and touching the growth, without cocaine. As soon as this could be done successfully, the next step was the selection of a suitable pair of forceps with which to remove the growth. Mackenzie's long forceps were half an inch too short, Mathieu's forceps were the right length, but were not large enough in the jaws to grasp the entire growth. (Specimen exhibited, preserved in alcohol.)

Next the galvano-cautery snare was tried and selected as the only means by which the growth could be removed *en masse*. The throat was thoroughly cocainized, a four per cent. spray was used for the pharynx, and a twenty per cent. solution applied to the larynx by means of an applicator. This was repeated three times at intervals of five minutes. After three or four trials the loop was properly adjusted so that the entire mass was engaged in the loop and quickly cut off. The throat was under perfect control, there was not the least pain experienced, and not a drop of blood lost. Patient was instructed not to speak at all for four days, and not above a whisper for one week. Voice fully restored and no trace of any abnormality at the end of one year from date of operation.

In closing the discussion which followed the reading of the paper, the author explained the means employed to prevent the growths from falling into the trachea in case they should not adhere to the instrument. During the period of training the patients are instructed to take a full inspiration after the instrument is in position. The patients are not informed that the growth is to be removed at this sitting and the inspiration is taken as usual at the time the word is given. In case the growth should fall from the instrument when severed, it is at once expelled by the force of the cough which follows.

A CASE OF TUBERCULOSIS OF THE PHARYNX.

Read in the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

BY J. E. BOYLAN, M.D.,
OF CINCINNATI, OHIO.
PROFESSOR OF LARYNGOLOGY AND OTOLOGY, WOMEN'S MEDICAL COLLEGE, MEMBER OF THE STAFF OF THE PRESBYTERIAN HOSPITAL, ETC.

Tuberculosis of the pharynx as a primary or local affection is of such exceptional occurrence and the nature of the affection so interesting, that I need hardly apologize for reporting a single case; my only regret in doing so, is that I have not been able, since committing myself for this occasion, to review the literature so thoroughly as to be in a position to state exactly, the very short time within which each of the comparatively few cases recorded proved fatal or to enumerate the isolated ones reported to have recovered.

Mrs. B., of Carlisle, Ky., 25 years of age, six months pregnant, was brought by Dr. Ricketts, accompanied by her husband and brother, to consult with me concerning a very painful throat affection which had recently developed, and to establish, if possible, its exact nature.

The patient gave the following history: She had had a catarrhal condition of the throat for two years past which had been treated by her doctor at home with applications of nitrate of silver, but which made no progress towards recovery. About a year ago finding that she had an irritating cough, she consulted Dr. McKenzie, of Cincinnati, who informed her that she was threatened with consumption and recommended an immediate change of climate. During a six months' sojourn in the south, she had more than regained her former weight, the cough had left her and she returned some months ago believing her health entirely restored. Within the last six weeks, however, there had developed a painful condition of the throat, quite different from her former affection, which was rapidly growing worse. Although her appetite was good and she had no cough, she suffered so intensely at every attempt to swallow that she postponed taking food as long as possible, and begged for some speedy relief, so that she might again eat with comfort. Patient was fairly nourished, somewhat pale, there was noticeable enlargement of the cervical glands on both sides. Upon inspecting the pharynx the following characteristic picture presented itself:

General pallor of the mucous membrane of the hard palate was noticeable at a glance, which pallor comprised on the left side, the whole roof of the mouth as far back as the anterior pillar, while on the right side, it gradually merged into an abnormal redness and then into a severe infiltration which remained sharply defined from the pale right side at the median line and which involved the uvula, the right anterior and posterior pillars, the tonsil and the right side of the posterior pharyngeal wall. Upon the right anterior pillar there was an oblong shallow ulceration with very irregular outline about as large as a silver three cent piece. In the immediate neighborhood of this ulceration as well as in other parts of the field of infiltration, a number of yellowish white and grayish white specks were to be seen, in places distinctly isolated, in others merging into indistinct whitish patches. At the base of the tongue on the right side was a similar irregular ulceration somewhat larger than the first; upon the tonsil a number of smaller irregular patches, which in places were confluent; upon the posterior pharyngeal wall also several filmy irregular whitish patches. Laryngoscopic examination showed the mucous membrane somewhat anæmic, the larynx otherwise apparently normal. In making a physical examination, a shorter and duller percussion note was noticeable over the left apex than over the right and a somewhat roughened expiration, beyond this I could detect nothing abnormal. After a repeated careful inspection, concurring with the opinion of Dr. Ricketts, I made a diagnosis of tuberculosis based upon the condition of the pharynx, and further assumed the unpleasant duty of notifying the husband and brother that, notwithstanding the present inactivity of the disease in the lungs a fatal and rapid termination was almost certain. They were greatly shocked and evidently incredulous. They expressed themselves as loath to accept this hopeless prognosis without further consultation and suggested that Dr. William Carson, in whose judgment they justly placed the greatest confidence, be called in. On the following morning Dr. Carson made a physical examination, as the result of which he upheld the diagnosis of tuberculosis, though he found the disease in the lungs at the time in an inactive condition,

The patient remained under my treatment for a week. Curetting, owing to the extent of the lesion, was not to be considered and the treatment was mainly directed towards relieving the suffering and facilitating nutrition. The application of cocaine and a 10 per cent. solution of menthol brought very transient relief; the cocaine had to be used each time before taking food and the menthol, when first applied, proved very painful; on the third day I began the insufflation of iodoform powder containing 1-16 gr. of morphine and was agreeably surprised at the amount of relief it afforded the patient. The effect lasted the greater part of the day so that she could swallow without pain till towards evening, and within the next three or four days there was a perceptible improvement in the condition of the pharynx.

September 23, she determined to return home where she would be more comfortable and she undertook to have the insufflations, upon which she became dependent, properly carried out.

On November 13, a letter from her husband informed us that the morphine and iodoform had proven most efficaceous. The family physician was using it and she had not only experienced very great relief but much of the sore place had healed and that she was in hopes of complete recovery.

A letter of a little later date brought news that the physician, then in charge of the case, ridiculed the idea of tuberculosis and had undertaken to treat her free of charge in order to demonstrate the error of the diagnosis arrived at in Cincinnati.

On January 8, less than two months later, word was received from the patient's husband that she had sunken into a condition of exhaustion and had succumbed to the disease, having given birth to her child some ten days before her death. Death occurred, therefore, within four months from the time the condition first made itself felt in the pharynx.

In the present state of our knowledge the question so frequently raised as to whether tubercular lesions in the pharynx and larynx are ever primary, can hardly lead to a satisfactory issue. While such lesions occur apparently independently, there will always be some ground for the sceptical to stand upon, as for example in the case of Schach who inclines to the view that when the affection is present in the pharynx, the disease always exists in the body in a dormant state, even though it be impossible to demonstrate it. Of far more practical importance is the question: "Can tuberculosis be recognized with certainty from the local lesion *alone*?" As a matter of fact we know that these lesions do present themselves at times when constitutional symptoms either do not suffice to establish the diagnosis, or cannot be detected at all, and we must then depend upon the local symptoms alone, for our diagnosis. Now in scanning the literature of the few cases reported, we find the lesion produced by tuberculosis in the pharynx possessed often of such distinctive features as to greatly facilitate the diagnosis; in fact in the majority of these cases tubercular nodules themselves were plainly visible in the neighborhood of the ulcerations and were verified post-mortem by the microscope in several instances, a condition which is almost never seen in the larynx. The entirely different character of the tubercular ulcer from the ulcer caused by syphilis has been nicely pointed out by Fraenkel, and both he and Tsembert have so carefully described the changes produced by the progress of the affection in this tissue, as to render its recognition far less difficult. In what proportion of cases the nature of the disease can be detected in its incipiency may not yet be established, but its exceptionally rapid course in this region, no doubt accounts for its more characteristic appearance. In the case above reported, the minute yellowish or grayish white specks scattered irregularly over the infiltration, isolated in places, in others becoming confluent and blurred; the shallow irregular ragged ulcer, the general pallor of the mucous membrane surrounding the infiltration, the excessive dysphagia, seemingly out of proportion to the severity of the lesion, presented an array of symptoms corresponding so strikingly to those described by the above mentioned observers that although I had seen a similar condition but once before, it appeared to me impossible to mistake it for any other affection.

PAPILLOMA OF EPIGLOTTIS, ETC.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY A. B. THRASHER, M.D.,
OF CINCINNATI, OHIO.

Miss Pearl S., æt. 17, Springfield, Ohio, was referred to me by Dr. Langdon, March 3, 1892. The vault of the pharynx was covered with adenoid tissue, rough and lobular, which extended from the region of Luschka's *tonsil back and down* over the posterior pharyngeal wall to a point on a level with the upper surface of the epiglottis. This tissue was apparently about half an inch thick in the center above, and gradually grew thinner as it extended downward and toward either side.

On pressing down the tongue a reddish glandular tumor was disclosed, which, on further examination proved to be attached to the epiglottis. The tumor was about the size of a large English walnut, the surface being divided at irregular intervals by deep seams and covered by small granulations, giving it somewhat the appearance of a large lobular strawberry. It was attached to the free border of the epiglottis, rather more on the upper than the under surface. The balance of the epiglottis presented a normal appearance as to both size and color. The weight of the neoplasm was so great as to press the epiglottis downward and its size so large as to completely shut off the under parts of the larynx from the laryngeal mirror. The voice was quite husky and a nervous cough had been present for *some time*. There was increasing dyspnœa for some three months, this being really the symptom which caused the patient to seek relief.

After the epiglottic neoplasm had been removed (which was accomplished by means of a wire ecraseur) the interior of the larynx was revealed. The movement of the left vocal cord was considerably impaired by some small sessile growths in the ventricle and over the left ventricular band, macroscopically quite like the tumor on the epiglottis.

After the lapse of two months there is as yet no tendency toward a recurrence of any of this tissue (that in the naso-pharynx and larynx having been removed by curette and galvano-cautery). No microscopic examination of the tissue was made, but the clinical history points to papillomata of larynx, while the pharyngeal growth seemed to differ in no respect from that which I have in other cases classed as adenoid tissue.

Discussion.

Dr. Casselberry, Chicago:—Concerning the diagnosis of laryngeal neoplasms Felix Semon has called attention to the fact that carcinoma, tubercle, etc., may have superficial papillomatous excrescences and that in order to get a correct result by microscopic examination, its entire growth must be examined. It is because this is rarely possible during life or before radical operation that the microscopic diagnosis of laryngeal growths is so unsatisfactory concerning the removal of laryngeal papillomata; I am glad to hear the galvano-cautery advocated. At the International Congress at Washington, in 1887, I had the pleasure of opening a discussion on this subject, and my paper consisted chiefly in advocating a specially constructed electrode for destruction of small sessile papillomata located on, above, or beneath the vocal cord. The idea was then criticised, among others, by Mr. Lennox Browne, who hesitated to use this instrument below the line of the epiglottis; under cocaine, however, I failed to see sufficient reason for such restriction. The electrode then exhibited has the correct laryngeal angle and descending arm has an anterior curve, the convexity of which assists in drawing forward the epiglottis. It is armed at the end with a short platinum loop from 4 to 6 inches in length, which can be bent to either side and made to impinge beneath the vocal cord when necessary. It has no shield because such only increases its bulk and interferes with vision, and because it is unnecessary, for the careful operator having introduced the instrument cold, will press the platinum loop outward against the neoplasm and away from the opposite side before heating it.

In certain cases it is superior to forcep because it will penetrate under illumination to points, such as the anterior commissure or beneath the cords, to which forceps, by reason of their larger size cannot pass, at least without obstruction to light and interference with vision.

Large growths, when possible, would best be removed by forceps and the base subsequently cauterized. The snare would require great caution to be exercised to avoid possible dropping of the neoplasm into the trachea. Concerning cocaine, care is necessary, strong solutions—20 per cent. on cotton application, and 10 per cent. in spray, are required to anæsthetize the larynx. These are capable in susceptible individuals of producing dangerous toxic symptoms. Before operating the susceptibility of the patient to cocaine should be tested at previous sittings; and if at the same time we train the patient by passing probes, etc., as was formerly customary before the use of cocaine, success will be more readily attained and by the use of less cocaine.

Dr. Casselberry, Chicago:—I would call attention to Dr. DuBlois' method of operating, *per vias naturales* by the finger nail. I believe it to be perfectly feasible, the larynx is high in children and can be reached and the soft papillomatous growths thoroughly scraped out of the larynx by a long finger-nail. If necessary an anæsthetic could be given and the procedure facilitated by pushing the larynx upward from without by the other hand.

I am disposed to deprecate thyrotomy as dangerous and often unsatisfactory. I recall a case in which a structure subsequently formed which together with recurrence of the growth finally caused death one night when the tracheotomy tube accidentally became dislodged.

Also another case in which recurrence necessitated the wearing of an intubation tube for years. I am disposed to avoid thyrotomy as much as possible, dealing tentatively with them by tracheotomy, intubation, and intralaryngeal manipulation until the child grows older.

Dr. Gibson:—The remarks of the several gentlemen who have spoken, are evidence that we have had much the same experiences under like circumstances.

The small size of the electrode or canula as compared with the forceps renders it possible to see exactly what we are doing.

To prevent the loss of the growth, by falling into the trachea, I instruct the patient to take a full inspiration just before I sever the growth. The patient had been repeatedly instructed to do so during the period of training, and did not have any idea as to my purpose at the time of removal. The object of this precaution is quite obvious.

To prevent toxic effects of cocaine, it has been my practice to instruct every patient in which cocaine is used in the upper air passages to *refrain from swallowing*, and have never experienced any constitutional effects of the drug when this instruction was followed.

The remarks on the occasional disappearance of papilloma after the use of stimulant and astringent, brings to mind what has frequently been debated in my mind, viz.: During the years that I was engaged in general practice it was my custom, when asked the best way to remove warts from the hands, to instruct them to apply castor oil thoroughly, and invariably the warts would vanish in a very short time.

Dr. Seiss has seen laryngeal papillomata absorbed under applications of iodine, etc. In structure these growths are the same as the ordinary dermal warts, which are well known to undergo absorption under mild applications of silver nitrate, etc.

Dr. Price Brown, Toronto, referred to a case of papilloma of left vocal cord, in a gentleman age 55, who was compelled to use his voice as his daily occupation. This was relieved and contraction of the papilloma secured by applications of thuja occidentalis, followed by treating with 10 per cent. of menthol in cellulose. Also to a case of double fibroma of larynx in a gentleman aged 37, suffering at same time from aneurism of aorta, the one arising between right arytenoid and right ventricular band, and projecting inwards over the glottis, impeding respiration; the other springing from right side of larynx immediately beneath the vocal cord. Under cocaine these were removed at a number of different sittings by galvano-cautery points, with result of relieving the dyspnœa. Some time afterwards the patient died of aneurism of aorta. The larynx which I obtained at the post-mortem exhibits the cicatrix of lower growth but not of the upper.

Dr. Lowman, Cleveland, O.:—A case of papilloma that passed under my observation proves that papillomata sometimes tend spontaneously to recovery. The patient was a child who had been hoarse for some months, and had rapidly grown dyspnœic in the last few weeks immediately preceding his application for relief. When first seen the breathing was so difficult that the face was cyanotic.

Laryngoscopic examination revealed a growth almost filling the chink of the glottis. Prompt interference was necessary and was obtained by a tracheotomy. Pneumonia and a prolonged illness followed the operation. After the recovery of the patient from the acute disease, the growth was inspected and found to have diminished in size. Repeated examinations at intervals of a few weeks showed that the growth was gradually becoming smaller. In less than a year all evidence of its appearance had disappeared. There had been no treatment whatever, unless the rest the tumor gained by reason of the tracheotomy can be considered treatment. The air passes through the larynx rapidly, and especially when the glottis is partially filled, and the opening into the trachea very much contracted. For this reason it may be that the papillomata grow more rapidly or swell more rapidly as the breathing grows more difficult and the friction greater.

The case shows that a papilloma may disappear, providing the larynx has rest from the air currents.

It is likely that the papilloma that disappears under treatment with astringents would subside under volitional or partial rest of the larynx.

Dr. Wadler, Indianapolis, called attention to the need of preparatory treatment, and said it was his custom to use stypics and astringents at the time, and frequently has witnessed their disappearance under such treatment. He also wished to emphasize the suggestion of Dr. Casselberry, of great caution in the use of cocaine, as he had witnessed dangerous symptoms in his early experience prior to his learning to exercise this great care.

Dr. Boylan said:—I have been interested in this case, in that I have one at present under treatment of a similar nature, excepting that the tumefaction is considerably larger: it being attached at and just below the anterior commissure and extending back so as to leave a comparatively small space for respiration posteriorly. The case was treated for asthma for some time till the tumefaction was finally discovered and came finally under my treatment. I hesitated for some time whether to perform tracheotomy at once or to attempt the removal through the pharynx. I finally decided to prepare for rapid tracheotomy and to then adopt the latter course. I succeeded in removing over one-half of the growth with the forceps, and thus averting the immediate danger of asphyxiation. Now while I appreciate all the advantages mentioned by the previous speakers in favor of the galvanocautery, I doubt if I shall be successful in reaching the remainder of the growth with the cautery, owing both to the age of the patient, who is a boy six years of age, and to the location of its attachment, and I am inclined to believe that I will stand better chances of reaching it with Schrotter's forceps.

ORBITAL AND OCULAR GROWTHS.

REPORT OF FOUR CASES WITH TWENTY-TWO PHOTOMICROGRAPHIC ILLUSTRATIONS.

Read in the Section of Ophthalmology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

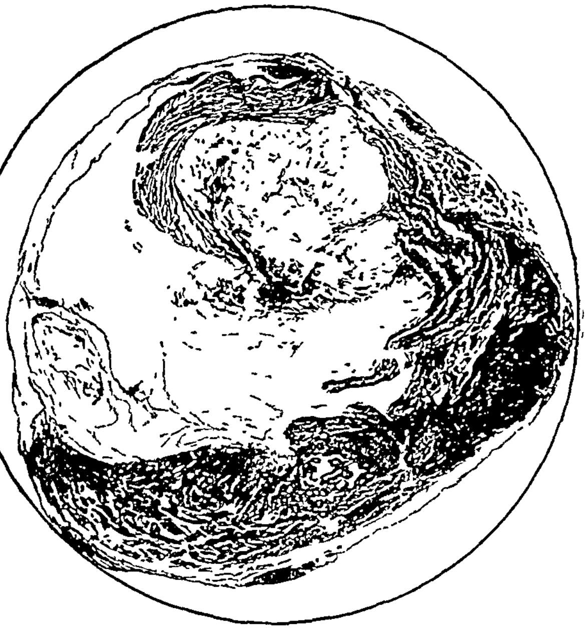
BY JOSEPH A. WHITE, A.M. M.D.,
SENIOR SURGEON TO THE RICHMOND, VA., EYE, EAR, THROAT AND NOSE INFIRMARY.
AND WM. M. GRAY, M.D.,
PATHOLOGIST OF THE ARMY MEDICAL MUSEUM, WASHINGTON, D. C.

I present these cases of tumors of the eye and orbit from my clinic at the Richmond, Va., Eye, Ear & Throat Infirmary operated on during this year, 1892, because I thought they were of sufficient interest for consideration. One is a case of melanotic sarcoma of the choroid that has as yet had no recurrence, but as this character of tumor is metastatic, there may be some manifestations of the same kind of growth elsewhere. The second is a sarcoma of the orbit which recurred twice after the original growth and eye were removed. The other two were growths of the orbit intimately connected with the periosteum; one in a woman 58 years of age, the other in a girl 16; one from the inner side of the orbit, extending from the orbital edge back and behind the eye to the sphenoidal fissure, the other from the external side following the same direction, and producing an apparently similar pathological condition of the eye and its annexes. Cases one and three were operated on by myself; cases two and four by Dr. John Dunn, Chief of Clinic at the Infirmary.

Case 1. Melanotic Sarcoma of the Choroid.—Geo. W. Wingfield, aged 54 years consulted me first, May 30, 1890. The left eye was blind, slightly exophthalmic, tension increased, the cornea clouded, the anterior chamber abolished, and the whole upper and outer part of the sclerotic of a dense black color. I diagnosed melanotic growth of the eye, and advised enucleation. This he declined to have done, and went home. I heard nothing from him until February 6, 1892, when he presented himself at my office with the eye so enormously enlarged that the lids could not be closed over it, the whole of the sclerotic perfectly black; patient suffering constant and excruciating pain. I gave him the same advice as before, and he consented to the removal of the eye. As cocaine had very little effect in anæsthetizing the eye, I gave chloroform, althogh I rarely have recourse to anything but cocaine in enucleation, and removed the globe. It was so distended, I was obliged to split the outer canthus to get it out of the orbit. Fearing the growth extended backward along the optic nerve sheath I grasped the nerve with a stout pair of fixation forceps before I cut the eye loose, so as to draw it out, and remove as much of it as possible. This I did after enucleating the eye, drawing the nerve out with the forceps already in position as far as possible, then putting another pair behind them and pulling again hand over hand as it were, and in this way I cut off about three-quarters of an inch of the nerve.

The eye was placed in Muller's fluid and sent to Dr. Wm. M. Gray, pathologist of the Army Medical Museum in Washington, and I append his report of the condition of the eye. I saw this patient on May 30 when the socket was clean and no signs of recurrence. I inserted an artificial eye and he returned home.

Dr. Gray sent me the following report of his examination of the eye; with the accompanying photographic plates and microscopic slides, both prepared by him in his laboratory.



SPECIMEN A.—Fig. 1. Large round and large spindle cell melanotic sarcoma of eye; developing from choroid coat.

Fig. 1. Shows a longitudinal antero-posterior section through the entire eyeball, and its contained tumor.

The tumor is composed of two seemingly distinct masses; one an intensely pigmented growth forming the peripheral portion, and a central mass, which is very slightly pigmented. The outer pigmented portion is made up of large round, spindle and stellate pigment cells, with a few small round unpigmented cells. The slightly pigmented central portion of the growth is composed of large round cells, somewhat epitheloid in appearance, and large spindle cells arranged in circular masses around small blood vessels; the walls of these blood-vessels are quite thick, and are composed of dense fibrous connective tissue. Fig's 2 and 3 show the circular cell masses in the slightly pigmented portion.

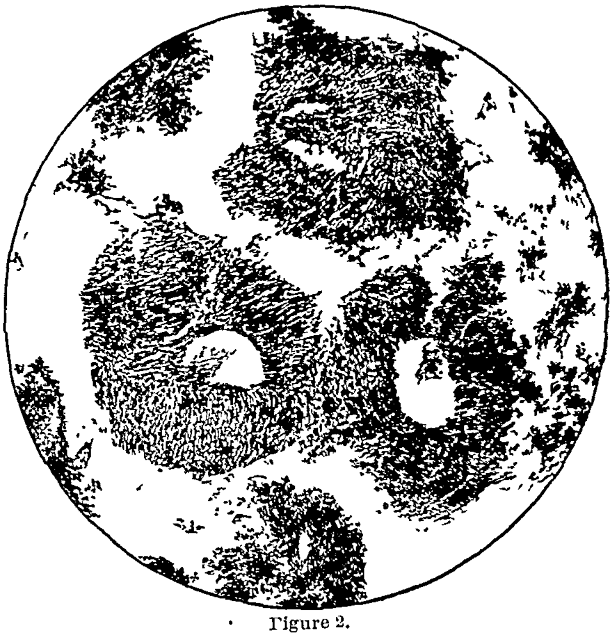


Figure 2.

Fig. 4. one of the circular cell masses on the border of the dense pigment portion. Fig. 5 shows the large round cells composing the greater portion of the entire growth; it is taken on the border of the densely pigmented portion, and contains a number of large round pigment cells. Fig. 6 from the same locality shows the same cells with an irregular shaped large spindle pigment cell, and several pigment masses. Fig. 7 shows the large spindle cells composing a portion of the central unpigmented circular cell masses. The greater portion of the sclerotic coat is obliterated by the *pigmented growth with which it is infiltrated*, and shows in several places the growth passing out into the orbit. Fig. 8. The retina has entirely disappeared.

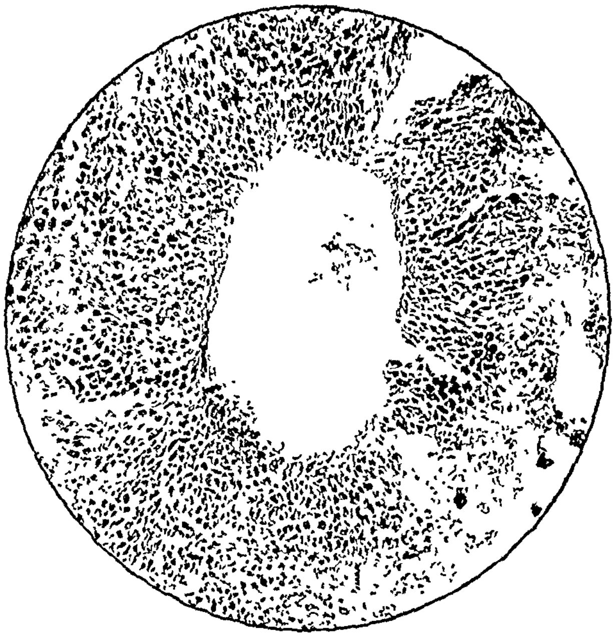

Figure 3.

Case 2.—Malignant Growth of the Orbit.—(Report given me by Dr. Dunn.) The patient, a full-blooded negro, aged 19 years, came Nov. 6, 1890, to the clinic of the Richmond Eye, Ear and Throat Infirmary. He had a growth protruding from between the lids of his left eye. This growth had made its appearance about nine months before, the patient being then 18½ years of age. The negro said that in July, 1890, the growth had been partially removed, *not entirely*, for he had been told that a small piece of it still remained. Since July the tumor had grown so rapidly that the day the negro came to the clinic it completely filled the inter-palpebral space, and the eye ball could be seen only by raising the upper lid. Examination of the tumor showed that it consisted of two parts, an encapsulated central part and its prolongations along the conjunctiva and subjunctival tissue of the lower cul-de-sac. The encapsulated portion was about the size of a hickory nut, and projected from the orbit below the eye ball, which it pressed upward and backward, and the movements of which it greatly hindered. The lower half of this central part protruded from between the lids and pressed so firmly against the inner canthus that the caruncle could not be seen. *The prolongations from the surface* of the main body of the growth had completely filled the lower cul-de-sac of the conjunctiva to within a few mm. of the outer canthus.

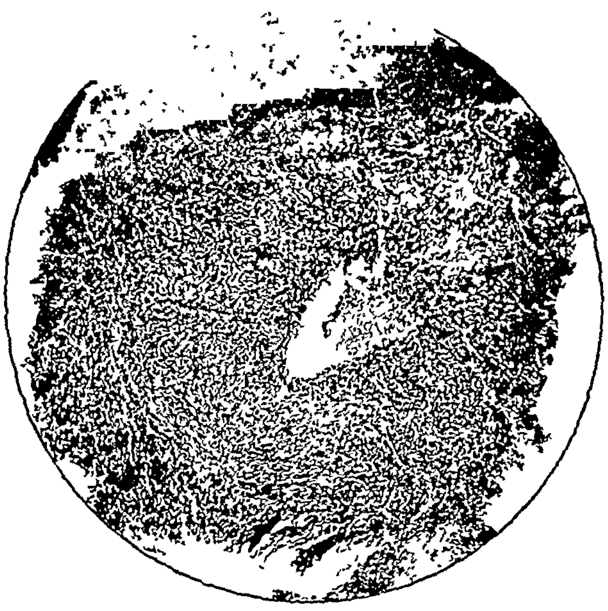

Figure 4.

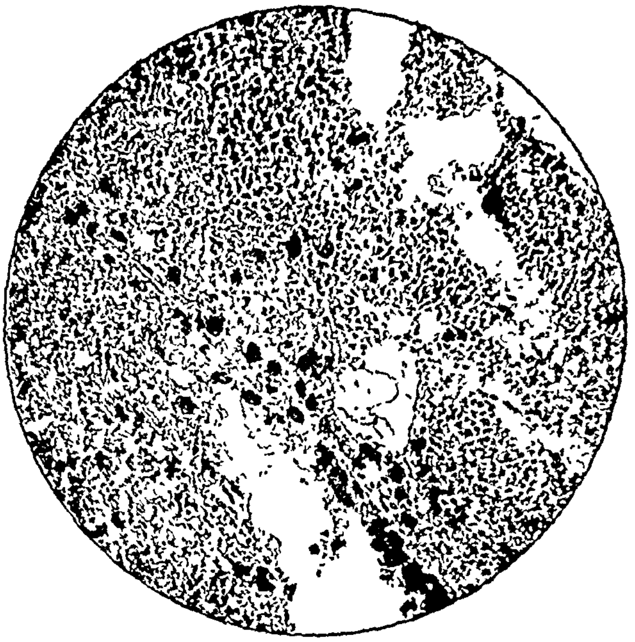

Figure 5.

The eye ball was perfectly healthy; so was the upper half of the ocular conjunctiva and the conjunctiva below immediately adjacent to the cornea. Centrally below, however, were seen running from the tumor to the edge of the cornea perhaps half a dozen small blood-vessels; these were all within a space of 6 mm. breadth. The surface of the tumor was red, rough, and, in places, warty, and was covered with a copious, dirty, purulent secretion. The tumor, though not painful in itself, was very sensitive to the least pressure, even when made through the lids.

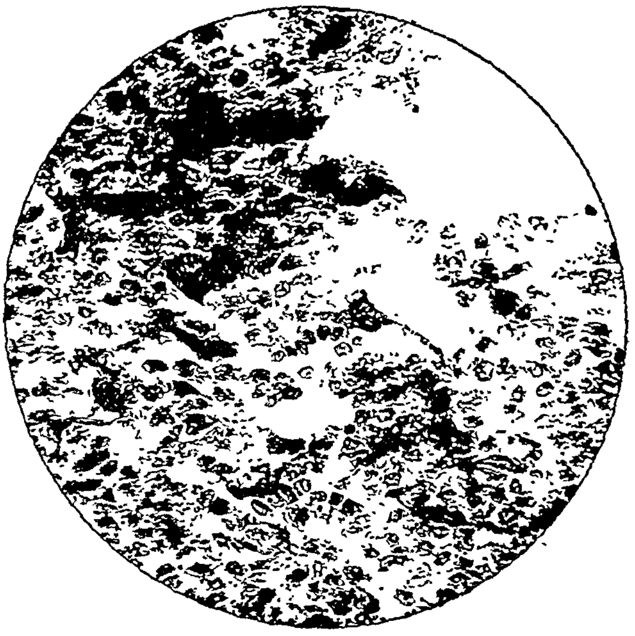

Figure 6.

Under cocaine, a small portion of the tumor was removed for microscopic examination, and patient was told to return in two days. The microscopic examination was unsatisfactory.

On Nov. 8, the patient returned. The growth was perceptibly larger than it was two days before, and I proceeded to remove it. An external canthotomy was done; then t h conjunctiva of the upper half of the ball was cut as in an enucleation, and the tendons of all the muscles, except the *inferior rectus* were cut. The nerve was next severed, and then the eye and the tumor were turned of the orbit from above, after which no trouble was had in removing the growth in what seemed its entirety. The main body of the tumor had the following measurements: From above downward, 32 mm., length 25 mm., from before backward, 15 mm.

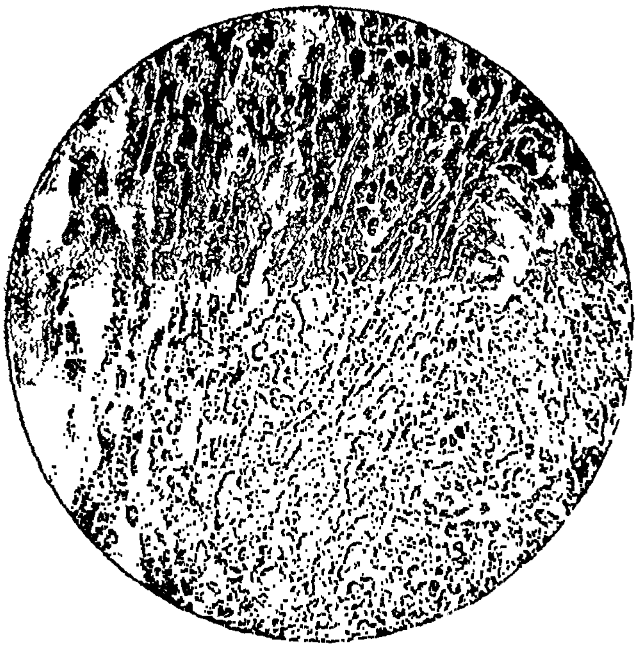

Figure 7.

The negro, who was a sailor, came to the clinic to have his eye dressed only for four days, after which time he joined his vessel.

He returned in January 1892. Up to January 1, there was no return of the tumor. It began to reappear early in this month, and by the 21st, it was two-thirds the size of a lemon, filling entirely the orbit, and protruding in a large mass from it. It was immovable in the orbit. Removed under chloroform. Found to have for the most part, a firm capsule, which was adherent to the eyelids, and everywhere to the walls of the orbit, even as far back as the entrance of the optic nerve. Large portions of the periosteum of the orbit stripped off in attempt to remove tumor. Orbit cleaned out. There were several sacs present in the tumor. Rupture of one showed it to be filled with thick cellular juice. Diagnosis, fibro-cystic sarcoma. Wound healed by remains of lid adhering to walls of orbit as far back as possible. No return up to May 30, 1892.

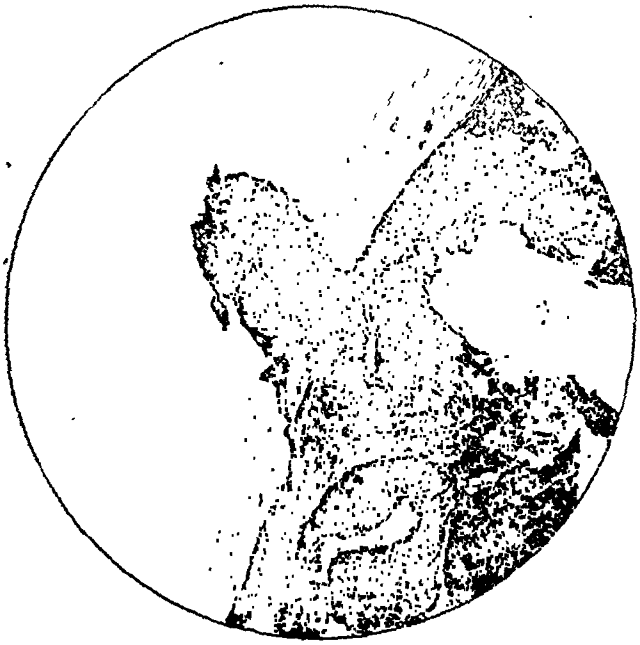

Figure 8.

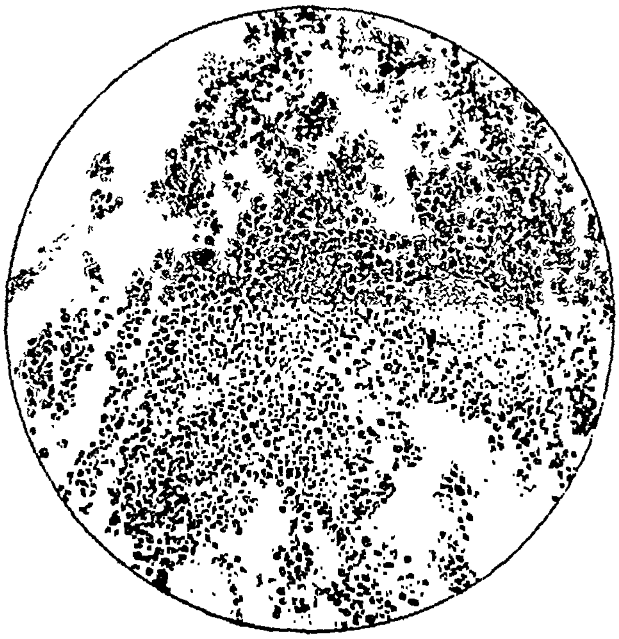
The growth was also sent to Dr. Gray, who gives the following report with illustrations.



Specimen B.—Fig. 9.—Small and Large Round Cell, Giant Cell Sarcoma of Orbit.

This growth is composed of round cells of various sizes; the larger cells have a very close resemblance to epithelial cells; in number the smaller cells predominate. Scattered through the cell mass are numerous typical giant cells, also some large round or irregular shaped cells, with multiple nuclei, which have not the characteristic appearance of giant cells, being almost entirely lacking in cell protoplasm.

There is very little intercellular tissue in the growth, no distinctly formed fibrous intercellular tissue, the cells seem to be connected by a finely granular material.

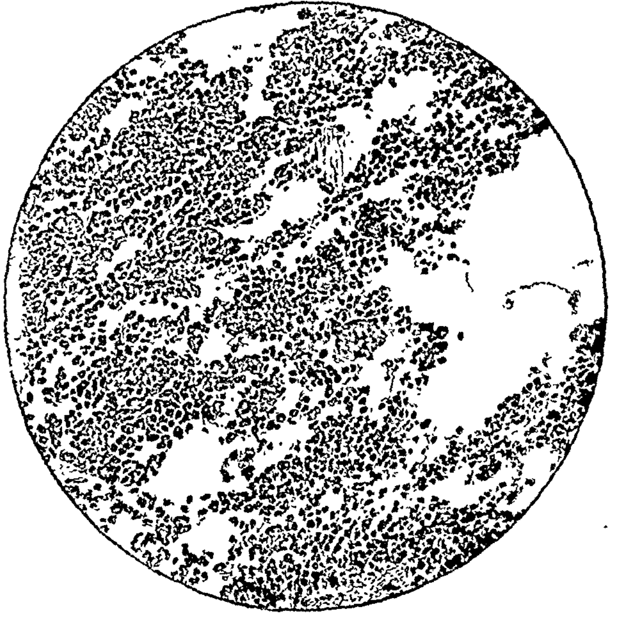


Figure 10.

The growth is quite vascular, some of the blood vessels have distinct fibrous walls, others are mere channels between the cells as shown in Fig. 9. Fig's. 10 and 11 of the same field show the round cells composing the body of the tumor, with a group of three giant cells. Fig. 12 shows several of the irregular shaped cells composed of multiple nuclei with a minimum of cell protoplasm.

Case 3.—Fibroma of the Orbit.—Mrs. S. C. Robinette, 58 years of age, of Crewe, Va., consulted me on February 15, 1892. She had been suffering great pain in the left side of her face for about three months, especially under and to the nasal side of the eye. It was thought at first that she had some trouble of the antrum. When I saw her the eye was tilted upwards, slightly exophthalmic, motion downwards was impeded, the inferior rectus being paretic, and there was pain on pressure over the inner and lower orbital edge. The vision was 20-30 with +1D. The refractive media were clear, but the optic nerve was engorged resembling "Stauung's papilla."

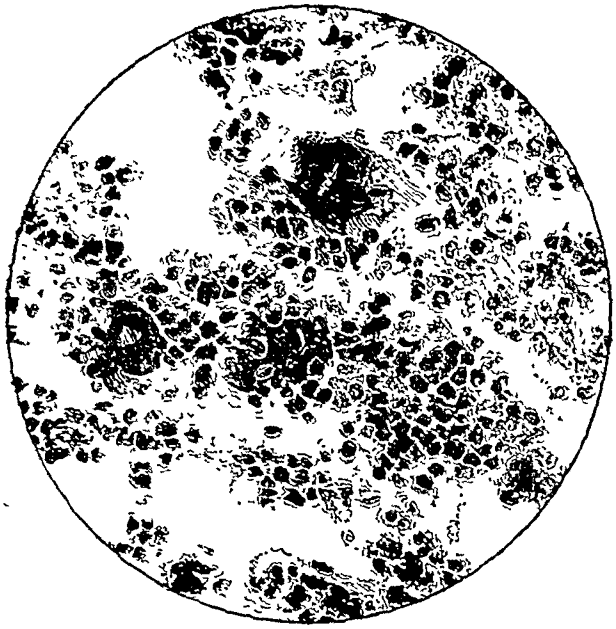

Figure 11.

By pushing the eye up and out and making firm pressure down and backwards under it at the inner orbital edge, a well marked projection be felt on the wall of the orbit. On the 16th, I exposed the orbital edge by an incision through the lid and attempted to remove the growth without enucleating the eye. I found it projected too far back in the orbit to do this successfully, and as I had not asked her permission to remove the eye, which was perfectly good as above shown, I contented myself with taking away as much of the growth as I could and sent it to Dr. Gray for examination

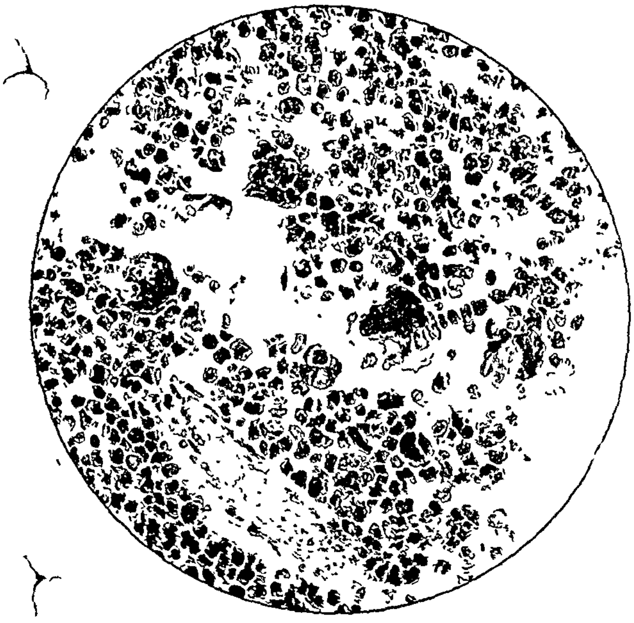

Figure 12.

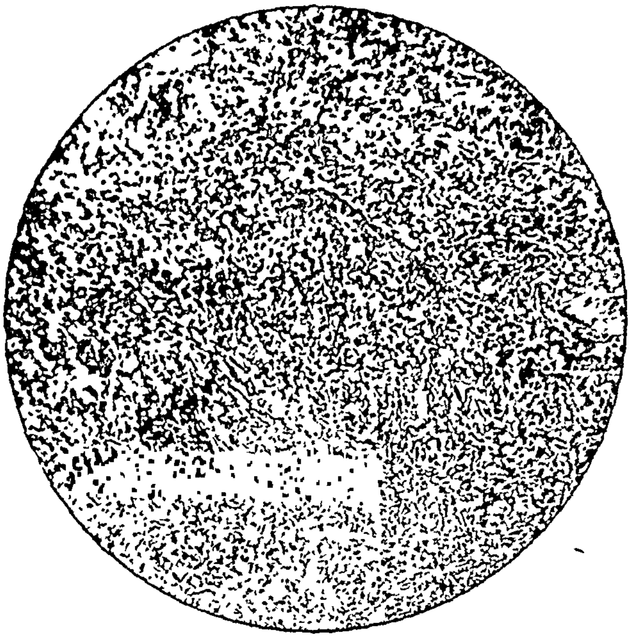
He reported it was composed of fibrous tissue, was not malignant, but thought the eye ought to removed, so as to thoroughly enucleate the remains of the growth. On March 29, I again operated by removing the eye and tumor as far back as I could. I found it extended to the sphenoidal fissure and possibly passed into the cranial cavity, as I am satisfied I simply amputated the growth at the bottom of orbit instead of removing it in toto. I sent this also to Dr Gray and asked him to make a report and give me sections I also sent the eye, thinking it might prove valuable for microscopic examination, being almost normal. I saw the patient again on April 27 and found no signs of the tumor in the orbit. Whether she will have a recurrence I cannot say with certainty, but think it probable.

Dr. Gray reported as follows, sending photos to illustrate his report:



SPECIMEN C.—Figure 13.—Soft Fibroma of Orbit.

This growth is made up of two portions; a central zone composed of very fine dense fibres, which have undergone some degeneration, probably due to pressure, and an outer zone composed of small and large bands of dense fibrous connective tissue running in all directions; the connective tissue of the outer zone is very rich in nuclei and very vascular; the nuclei are composed of small round and small spindle cells. Some of the blood-vessels of the outer zone have well formed walls, but the majority are simple channels, well defined, with sometimes a single layer of cells forming their walls. Figures 13 and 14 show portions of the central and outer zones. Figures 15 and 16 show the richly nucleated fibrous outer zone, with the small blood channels. Figure 17 shows a very richly nucleated portion with two of the larger blood channels, whose walls are ormed by a single layer of cells.

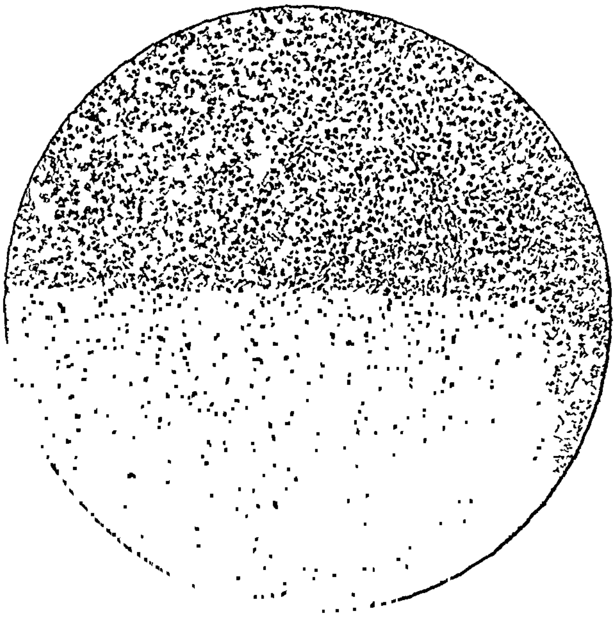


Figure 14.

Case 4.—Tuberculous Growth of Orbit.—(Report given me by Dr. Dunn.) Mary, aged 16, first had eye trouble in August, 1891, no clear history of course but probably traumatic. First seen in May, 1892. Protrusion of left eye, apparent paralysis of left upper lid. Tangent to cornea O. S. 7 mm., in advance of tangent to anterior surface of cornea of O. D. Movement of the eye impeded in all directions. Diplopia when patient looks to the left. V. = 20-30. No inflammatory symptoms, overfilling of vessels over the insertion of external rectus O. S. No pain upon pressure upon ball. Severe neuralgic attacks about the eye. Just below external angle of the orbit, contiguous with the bone can be felt a hard, firm though perhaps slightly elastic, immovable growth, which extends back into the orbit. The width and thickness of the portion of the growth that can be felt is about that of a lead pencil. To the touch, so hard, incompressible and immovable was this part of the growth, that it suggested osteoma.

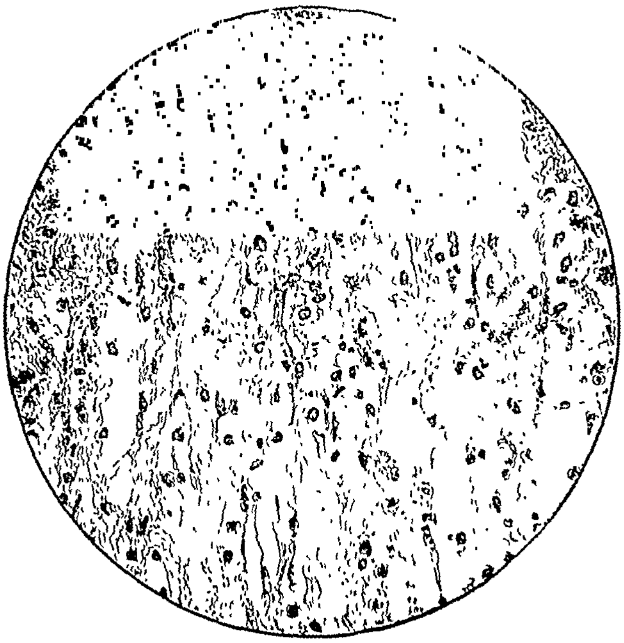

Figure 15.

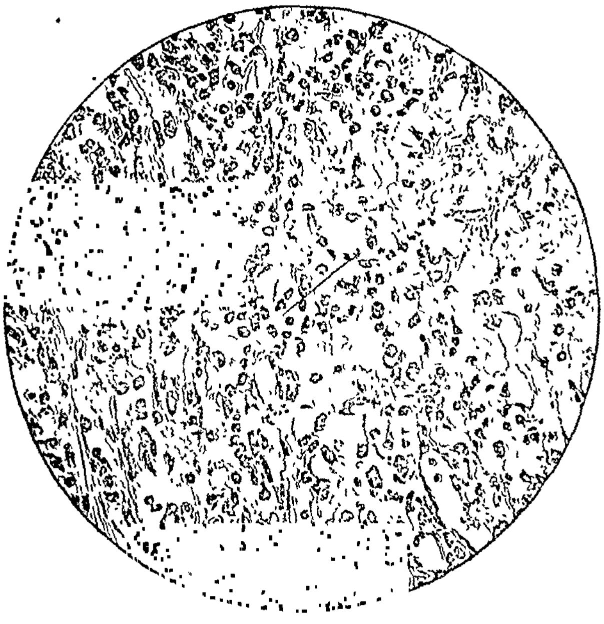

Figure 16.

In [illegible] painful on pressure. Operation, outer canthus [illegible] downward incision, about 1 inch; flap held [illegible] Tumor found adherent to the edge of the orbit, and to the periosteum of the orbital plates of the malar, superior maxilla and sphenoid. Origin near entrance of optic nerve into orbit; but not from optic fibrous sheath. Adherent to external rectus. Eye saved; vision good. Wound healed by first intention. Probably internal squint, due to cutting the external rectus.

This growth was peculiar in shape. It resembled a small pear which had been compressed, the base at the orbital edge, the apex and stem far back in the orbit. It was about three quarters of an inch wide at the base and tapered to a point with a long cord-like projection about three quarters of an inch long. The length of the growth itself was more than an inch. It was sent to Dr. Gray who gave me the following interesting report:

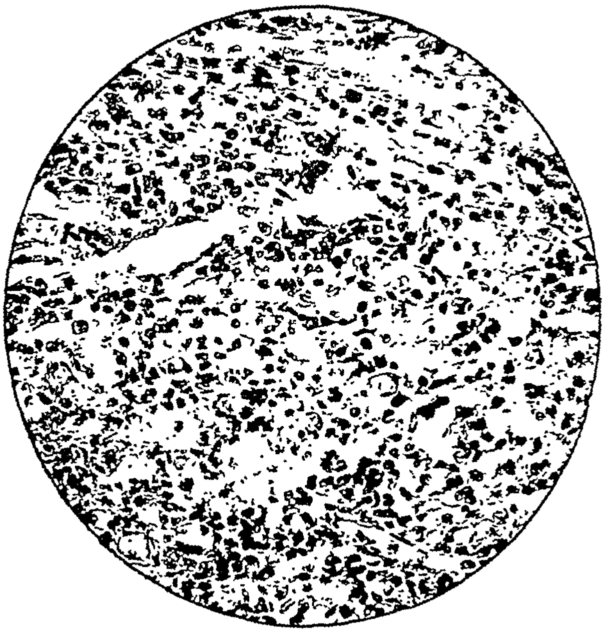

Figure 17.

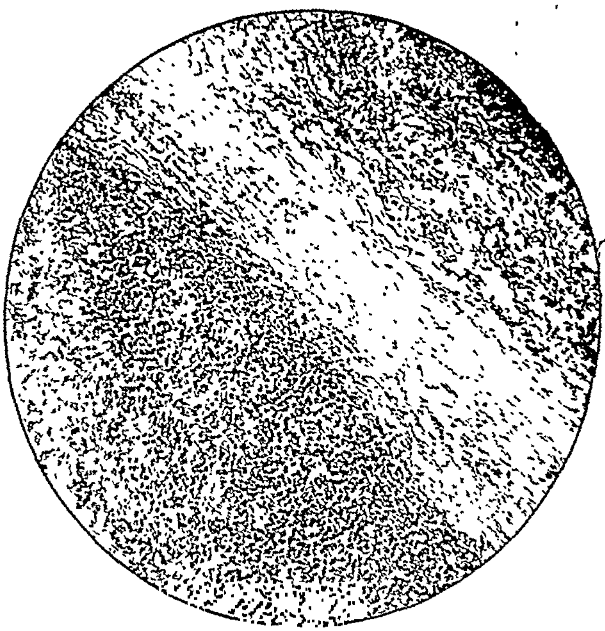

SPECIMEN D.—Figure 18.—Miliary Tuberculosis of Orbit.

This specimen is composed of bands of very dense fibrous connective tissue; between the fibrous bands is an extensive lymphoid infiltrate, while throughout the tissue are numerous aggregations of these cells, forming nearly typical miliary tubercles. These cell aggregations differ from the typical tubercles in not containing giant cells. The tissue contains giant cells however, but they are only found far removed from the tubercles among the cells infiltrating the fibres.

Repeated attempts at staining failed to demonstrate tubercle bacilli in the tissue.

Fig's. 18 and 19 show the lymphoid infiltrate between the connective tissue fibres.

Fig. 20 shows two of the cell aggregations forming the so-called miliary tubercles.

Fig. 21 one of the tubercles more highly magnified.

Fig. 19 also shows two giant cells imbedded in the infiltrating cells.

Fig. 22 one of the giant cells more highly magnified.

In case 1 the growth seems to have started from the ciliary body between the superior and external rectus, and gradually involved other portions of the uveal tract, but at no time did it perforate the coats of the eye, as far as could be determined macroscopically, but the microscope shows it had extended through the sclerotic. As a melanotic tumor is among the rarer forms of intraocular growths I considered it of sufficient interest to present here.

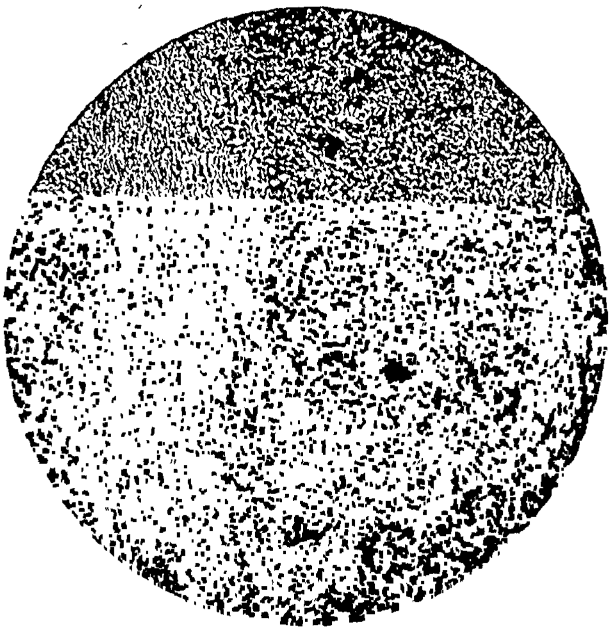

Figure 19.

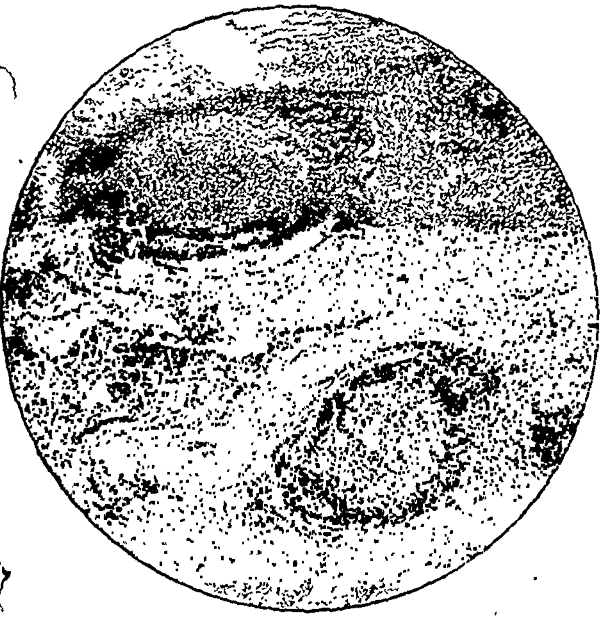

Figure 20.

Case 2 was seen at too late a stage of the development of the neoplasm to determine its point of origin with certainty, but it probably developed in the subconjunctival tissue below the eyeball, as even when the enucleation became imperative, the eye was perfectly healthy, and the *tumor had no attachments to the latter except by a band* of tissue uniting it to the sclero-corneal margin. It was a purely extra-ocular growth, developing in the loose subconjunctival tissue and enveloped in a dense connective tissue capsule, which whilst connected with the orbital walls completely *isolated the tumor from the deep orbital tissues.*

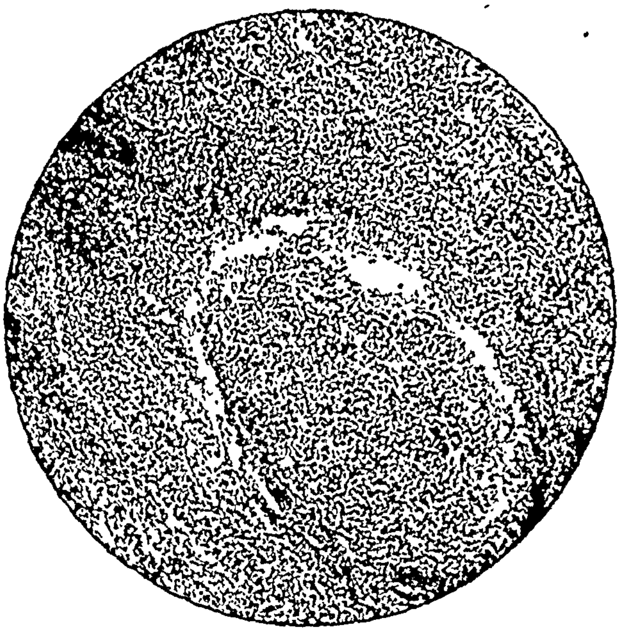

Figure 21.

Case 3 is of interest from the fact that it was fibroid apparently originating from the orbital portion of the superior maxilla, as this was the only point of close attachment, except at the bottom of the orbit, where it seemed attached to the sphenoid, if it did not pass into the cranial cavity.

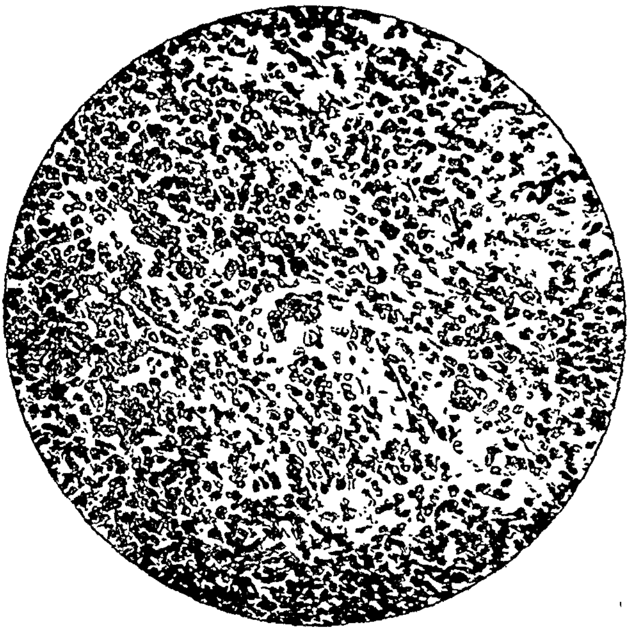

Figure 22.

There was no evidence of its originating from any of the neighboring cavities, and had no attachments to any of the contiguous bony structures.

Case 4, a tuberculous growth as reported by Dr. Gray, was to me different from any orbital tumor I had ever seen. Its point of origin could not be determined, but it seemed firmly attached to the outer and lower orbital wall, and after its marginal adhesions had been freed, it was easily enucleated with knife handle and finger. I assisted Dr. Dunn in the operation, and I found little trouble in tearing up the attachments, after I was able to get my finger behind it. It seemed to be encapsulated and came away solidly and with perfect contour. I suppose others have seen similar orbital growths, but I can find little or nothing in regard to them in the literature accessible to me. How a growth microscopically analogous to, if not identical with miliary tubercle could develop in such a subject, I do not understand.

The girl is an exceptionaly stout, sturdy, hearty individual with no signs of disease of any other organ, a picture of perfect health.

This fact and the rarity of this form of orbital tumor makes the case a particularly interesting one.

In conclusion, I wish to express my appreciation of Dr. Gray's excellent work in his part of this contribution to the proceedings of the Section, as without his help my record of these cases would have had little interest.

I have also to thank Dr. Dunn for writing up the cases he operated on at the clinic, especially as one of them, case 4, is the most interesting one presented.

EARLY NATIONAL LEGISLATION ON THE SUBJECT OF QUARANTINE.

BY STEPHEN SMITH, M.D.,

OF NEW YORK.

(Concluded from page 412.)

During the summers of 1796 and 1797 the yellow fever again prevailed widely and increased the public alarm by the extension of its area and the fatality of its attacks.

On the opening of the Fifth Congress, at Philadelphia, November 23, 1797, the President, John Adams, commenced his speech to the Houses as follows:

> "I was for some time apprehensive that it would be necessary, on account of the contagious sickness which afflicted the city of Philadelphia, to convene the national legislature at some other place. This measure it was desirable to avoid, because it would occasion much public inconvenience and considerable public expense, and add to the calamities of the inhabitants of this city, whose sufferings must have excited the sympathy of all their fellow-citizens; therefore, after taking measures to ascertain the state and decline of the sickness, I postponed my determination, having hopes, now happily realized, that, without hazard to the lives or health of the members, Congress might assemble at this place, where it was next by law to meet. I submit, however, to your consideration whether a power to postpone the meeting of Congress, without passing the time fixed by the Constitution, upon such occasions, would not be a useful amendment to the law of 1794."

In the address of the House in response to the speech of the President, which it was at that time customary to make, the subject was noticed as follows:

> "While our sympathy is excited by the recent sufferings of the citizens of Philadelphia, we participate in the satisfaction which you are pleased to express, that the duration of the late calamity was so limited as to render unnecessary the expense and inconvenience that would have been incident to the convention of Congress in another place, and we shall readily attend to every useful amendment to the law which contemplates the event of contagious sickness at the seat of government."

Congress does not seem, however, to have taken any action at this session.

During the summer of 1798 yellow fever again appeared, and this time it attained the proportions of a national scourge. It prevailed at Portsmouth, N. H.; Boston and Salem, Mass.; Westerly, R. I.; Hartford, Stonington, New London and Norwalk, Conn.; New York; Bridgeton and Woodbury, N. J.; Philadelphia, Marcus Hook and Chester, Pa.; Wilmington, Christina, Duck Creek and New Castle, Del.; Baltimore, Md.; Norfolk, Petersburg and City Point, Va.; Charleston, S. C.

At the opening of the third session of the Fifth Congress, December 8, 1798, President Adams thus addressed the two Houses:

> "While with reverence and resignation we contemplate the dispensation of Divine Providence in the alarming and destructive pestilence with which several of our cities and towns have been visited, there is cause for gratitude and mutual congratulations that the malady has disappeared, and that we are again permitted to assemble in safety at the seat of government for the discharge of our important duties. But when we reflect that this fatal disorder has within a few years made repeated ravages in some of our principal seaports, and with increased malignancy, and when we consider the magnitude of the evils arising from the interruption of public and private business, whereby the national interests are deeply affected, I think it my duty to invite the legislature of the Union to examine the expediency of establishing suitable regulations in aid of the health laws of the respective States; for, these being formed on the idea that contagious sickness may be communicated through the channels of commerce, there seems to be a necessity that Congress, who alone can regulate trade, should frame a system which, while it may tend to preserve the general health, may be compatible with the interests of commerce and the safety of the revenue."

Petitions were prepared to be laid before Congress, both in Philadelphia and New York, asking aid of the general government. The Philadelphia committee went so far as to propose non-intercourse with the West India ports during the dangerous months of the season. The New York committee objected to such stringent measures, and a modified memorial was adopted. The health officer of New York, Dr. Richard Bayley, urged the formation of quarantine establishments at a proper distance from seaport cities, where ships could be examined and, if necessary, thoroughly cleansed and disinfected.

The subject was again brought before Congress by Mr. Smith, of Maryland, who was now chairman of the Committee of Commerce, as appears from the following extract from the Annals of Congress:

> "On Wednesday, January 23, 1799, Mr. Smith, of Maryland, from the Committee of Commerce, reported a bill respecting quarantine and health laws, which was read and committed.
>
> "On Monday, January 28, 1799, on motion of Mr. Smith, of Maryland, the House went into a committee of the whole, on the bill respecting quarantine and health laws; Mr. Rutledge in the chair.
>
> "The bill was read as follows:
>
> "SECTION 1. *Be it enacted, etc.*, That the quarantine and other restraints which shall be required and established by the health laws of any State, or pursuant thereto, respecting any vessel arriving in, or bound to, any port or district thereof, whether from a foreign port or place, or from another district of the United States, shall be duly observed by the collectors, and all other officers of revenue of the United States, appointed and employed for the several collection districts of such States respectively, and by the masters and crews of the several revenue cutters, and by the military officers who shall command in any port or station upon the sea-coast; and all such officers of the United States shall be, and they hereby are, authorized and required faithfully to aid in the execution of such quarantine and health laws, according to their respective powers and precincts, and as they shall be directed from time to time by the Sec-

retary of the Treasury. And the said Secretary shall be, and is hereby authorized, when a conformity to such quarantine and health laws shall require it, and in respect to vessels which shall be subject thereto, to prolong the terms limited for the entry of the same, and the report or entry of their cargoes, and to vary or dispense with any other regulations applicable to such reports or entries: *Provided*, That nothing herein shall enable any State to collect a duty of tonnage or impost without the consent of the Congress of the United States; *And provided*, That no part of the cargo of any vessel shall, in any case, be taken out or unladen therefrom otherwise than as by law is allowed, or according to regulations hereinafter established.

"Sec. 2. *And be it further enacted*, That when, by the health laws of any State, or by the regulations which shall be made pursuant thereto, any vessel arriving within a collection district of such State shall be prohibited from coming to the port of entry or delivery by law established for such district, and it shall be required by such health laws that the cargo of such vessel shall, or may be, unladen at some other place within or near to such district, the collector authorized therein, after due report to him of the whole of such cargo, may grant his special warrant or permit for the unloading and discharge thereof, under the care of the surveyor, or of one or more inspectors, at some other place where such health laws shall permit, and upon the conditions and restrictions which shall be directed by the Secretary of the Treasury, or which such collector may, for the time, reasonably judge expedient for the security of the public revenue: *Provided*, That in every such case all of the articles of the cargo so to be unladen shall be deposited, at the risk of the parties concerned therein, in such public or other warehouses or inclosures as the collector shall designate, there to remain under the joint custody of such collector and of the owner or owners, or master or other person having charge of such vessel, until the same shall be entirely unladen or discharged, and until the goods, wares or merchandise which shall be so deposited may be safely removed, without contravening such health laws; and when such removal may be allowed, the collector having charge of such goods, wares or merchandise may grant permits to the respective owners or consignees, their factors or agents, to receive all goods, wares or merchandise which shall be entered and whereof the duties accruing shall be paid or secured according to law, upon the payment by them of a reasonable rate of storage, which shall be fixed by the Secretary of the Treasury for all public warehouses and inclosures.

"Sec. 3. *And be it further enacted*, That there shall be purchased or erected, under the orders and with the approbation of the United States, suitable warehouses, with wharves and inclosures, where goods and merchandise may be unladen and deposited, from any vessel which shall be subject to a quarantine, or other restraint, pursuant to the health laws of any State as aforesaid, at such convenient place or places therein as the safety of the public revenue and the observance of such health laws may require: *Provided*, That the site of all such warehouses and wharves, with such other adjoining lands as may be necessary for the public uses hereby authorized, shall be ceded to the United States by the State wherein the same shall be.

"Sec. 4. *And be it further enacted*, That when by prevalence of any contagious or epidemical disease in or near the place by law established as the port of entry for any collection district, it shall become dangerous or inconvenient for the collectors or other officers of the revenue employed therein to continue the discharge of their respective offices at such ports, the Secretary, or in his absence, the Comptroller of the Treasury of the United States, may direct and authorize the removal of the collector, and the other officers employed in his department, from such port to any other more convenient place within, or as near as may be to such collection district, where such collector and officers may exercise the same authorities, and shall be liable to the same duties, according to existing circumstances, as in such lawful port or district; and of such removal, public notice shall be given as soon as may be."

The following discussion ensued:

"Mr. Livingston, of New York, moved to strike out the proviso at the close of the third section, as it might, in his opinion, be productive of delay in some cases, and of danger in others. Some of the State legislatures might not be in session before the evil intended to be guarded against returns upon us, and it might interfere with the jurisdiction of towns or cities of which those sites form a part. He knew that there were some gentlemen in the House who think no money ought to be expended by the United States for any public works until cessions of the jurisdiction are made. This may be proper, with respect to forts and magazines with which State jurisdiction might interfere; but this being merely a civil jurisdiction, and so far from interfering with any State jurisdiction, is to coöperate with the State regulations, gentlemen may vote for striking out this clause, without parting with their favorite doctrine.

"Mr. Dayton, of New Jersey, trusted the motion would not prevail. It was negatived, there being only 23 votes in favor of it.

"Mr. Livingston, of New York, then moved to amend the bill by striking out the second line of the third section with the words 'and with approbation,' which was certainly surplusage. Agreed to.

"Mr. Waln, of Pennsylvania, said if it were proper to cede the land on which the warehouses are built, he did not think it would be to cede the sites of wharves to the United States. He did not think it right, for instance, to cede the jurisdiction of any wharves which might be built in the vicinity of this city to the United States. He, therefore, moved to strike out the words 'and wharves.'

"Mr. Sewall, of Massachusetts, hoped the gentleman from Pennsylvania would not insist upon this motion. No wharves would be erected where wharves now are; and if the United States are at the expense of erecting the wharves, they ought to have the jurisdiction of their sites, as well as of the sites of warehouses.

"This motion was negatived, there being only 12 votes for it.

"The committee rose and reported the bill, when Mr. Harper renewed the motion for striking out the proviso in the third section, for the reasons he urged in support of the former motion, and because this cession would be of no use to the United States; and after some few observations upon it, the motion was carried, 40 to 31.

"On motion of Mr. Sewall, of Massachusetts, the following section was added, repealing a law of the first session of the Fourth Congress, respecting quarantine:

"Sec. 5. *And be it further enacted*, That the act entitled '*An act relative to quarantine*,' passed in the first session of the Fourth Congress of the United States shall be, and the same is hereby, repealed.'"

January 29, 1799, the bill was read a third time and passed.

In the Senate an additional section was added, as follows:

"Sec. . *And be it further enacted*, That whenever in the opinion of the Chief Justice, or in case of his death or inability, of the senior associate justice of the United States, a contagious sickness shall render it hazardous to hold the next stated session of the said court at the seat of government, it shall be lawful for the Chief or such associate justice to issue his order to the marshal of the district within which the Supreme Court is by law to be holden, directing him to adjourn the said session of the said Court to such other place within the same or an adjoining district, as he may deem convenient; and the said marshal shall thereupon adjourn the said Court by making publication thereof in one or more public papers printed at the place by law appointed for holding the same, from the time he shall receive such order, until the time by law prescribed for commencing the said session. And the district judges shall respectively, under the same circumstances, have the same power, by the same means, to direct adjournment of the district and circuit courts within their several districts, to some convenient place within the same, respectively."

This amendment was concurred in by the House, and the bill, as amended, was passed.

It was approved February 25, 1799.

In 1799–1800 there was much alarm in Europe in regard to the spread of the plague, and stringent quarantine measures were adopted by the British Government. There was some apprehension that the pestilence would be imported into this country, and Congress was urged to consider the question. On Friday, February 28, 1800, Mr. Waln, of Pennsylvania, presented a memorial from the health office in Philadelphia, stating that in consequence of the plague having raged in Morocco, Great Britain had enacted very strict quarantine laws, but although the port of Philadelphia might be watched by all the vigilance in the power of the health office, there was no general law to keep that most dreadful scourge of the human race from being introduced into some ports of the United States. They prayed the attention of Congress thereto. Referred to the Committee of Commerce.

Wednesday, March 19, 1800, a memorial of the select and common councils of the city of Philadelphia was presented to the House and read, praying that Congress may take such precautionary measures to prevent the introduction of the plague, which has for some time prevailed in the countries bordering on the Mediterranean, as to their wisdom shall seem meet. Referred to the Committee on Commerce and Manufactures.

Friday, April 25, 1800, the Speaker laid before the House a letter from the Secretary of the Treasury, accompanying an estimate for an appropriation of moneys for carrying into effect the act respecting quarantine and health laws, which were read and ordered to lie on the table. No other action was taken, nor was the subject alluded to for upwards of two years.

On Friday, January 8, 1802, Dr. Samuel L. Mitchell, of New York, now for the first time a member of the House of Representatives, offered the following resolution:

"*Resolved*, That a committee be appointed to inquire and report whether any, and what, alterations are necessary to be made in the 'act respecting quarantine and health laws.'"

It was ordered that Mr. Mitchell, of New York; Mr. Eustis, of Massachusetts; Mr. Leib, of Pennsylvania; Mr. Archer, of Maryland; Mr. Lowndes, of South Carolina, be appointed a committee pursuant to the said resolution.

Dr. Mitchell was an active participant in the medical controversies in regard to the origin of yellow fever in New York. He was a strong advocate of non-contagion, and believed that pestilential diseases were frequently engendered on board of filthy ships. He did not, therefore, believe in quarantines for detention simply, but only for purification of ships. He was also an ardent believer in the efficacy of alkalies as an antidote to septic poisons, and hence advocated alkalies, vigorously applied, instead of fumigation.

In a letter to Dr. Richard Bayley, the health officer of New York, dated July 1, 1801, he concludes a history of quarantines with the following statement of his views:

"Vessels retain the pestilential because, 1, from their structure it is difficult to introduce a sufficiency of fresh air to waft away the infectious gas; 2, from the manner of their construction it is also exceedingly difficult to scrub and scour and cleanse them by lime and alkalies, as houses are purified; and 3, from the preposterous custom of pronouncing a vessel clean after she has been pumped out and fumigated with tar and brimstone; while in fact, she is as foul *after* being smoked as she was *before*. The negligence of navigators and owners of vessels on these points renders it absolutely necessary for public authority to interfere. All that I think necessary in the business is that the never-failing method of *house-cleaning* should be applied to *ship-cleaning* in the way that you have adopted with such happy success. And if the time shall arrive when sea-vessels shall be kept as clean as genteel habitations on shore, their crews and passengers will suffer as little by infection and pestilence; and then the dream of importing pestilential diseases from foreign countries will be forgotten or insisted on no more as a reality. And that this is not a mere conjecture but a practical fact, is confirmed by the experience of the Dutch navigators; for they, carrying with them to sea the habits of that precise and unequaled cleanliness which prevails on shore in the United Netherlands, are rarely or never troubled with the fevers, the plagues and the infectious distempers which incessantly harass the nastier nations of the earth."

The special object which Dr. Mitchell had in view in offering the above resolution seems to have been to give publicity to his opinions in regard to the virtues of alkalies as an antidote to septon (septic poisons). He says:

"The particular object aimed at is to cleanse ships and vessels by means of *alkaline salts and lyes*, and to explode the miserable and delusive practice of fumigation; in short, to apply the modes of *cleaning houses to the purification of ships*. This will reduce the quarantine of vessels *to the simple process of cleansing by alkalies*, and eventually remove from commerce most of the tedious and burdensome restraints under which it is now groaning. Science will have a glorious triump, and the American Government will set a noble and liberal example to the whole civilized world."

On Tuesday, March 9, 1802, the following petition was referred to that committee:

"A petition of sundry merchants residing in the city and State of New York, importers of cotton, hides, and other raw materials, for manufacture, was presented to the House and read, stating that the inconveniences and expense to which the petitioners are subjected by being obliged, under the quarantine laws of the said State, to unload and deposit for a limited time in every year, the said articles on Staten Island, and praying that they may be permitted to keep the same in the public storehouse of the United States erected on the island aforesaid, free from storage, during the period of such quarantine."

"*Ordered*, That the said petition be referred to the committee appointed on the 8th of January."

The committee made no report at that session.

At the following session it appears that on the 15th of February, 1803, the House referred to that committee the following resolution:

"That provision ought to be made by law for the regulation of quarantine within the District of Columbia." Finally, on the 25th of February, 1803, Dr. Mitchell submitted his report, which is remarkable for its intelligent recognition of the unhealthfulness of ships, and the better methods of purification. The report is as follows:

The term "quarantine" has been used, in the commercial world, to denote the detention of ship or vessel at a convenient place, some distance from port, for the space of forty days, for the purpose of freeing her from contagion and infection, supposed to have been transported in her from foreign places; latterly it means any shorter number of days. Under the persuasion that their own cities and habitations were exempt from such contagion and infection, and that these destructive agents were always introduced from remote places, less salubrious than their own, mankind have taken great pains to protect themselves from external attacks of the distempers which they believed to be prevalent among their neighbors or strangers. By the presumption that contagion was frequent in many foreign settlements, and was readily transported from country to country by commercial communications, have the nations of the earth been influenced in framing the rules and the means of restraint imposed upon their mutual intercourse. They have often looked on each other as lazars or lepers, and treated visitors and passengers at certain seasons as such.

The importance of the subject, as well to the commerce and revenue of the United States as to the happiness and security of her citizens, has induced your committee to look into it carefully. They have endeavored to gather facts and to deduce therefrom correct conclusions; and, upon the most complete investigation which they have been able to give the subject, they are decidedly of the opinion that the ideas generally entertained concerning quarantines are very erroneous.

It is true that certain diseases which afflict mankind, such as small-pox, for example, may be transferred from one person to another; but of late doubts have been entertained in the minds of some of the best observers, of such as have had great opportunities for knowing and judging, whether the like contagiousness is true of yellow fever and the fever infecting ships.

Sickness of distant places and the danger arising from any intercourse with them is one of the trite themes of remark almost everywhere. At the same time few people can be brought to acknowledge the noxiousness of the soil and atmosphere of the place of their permanent residence. Therefore the inhabitants of the West India Islands are positive that they import yellow fever from Boston, New York, Philadelphia, and Baltimore; while the inhabitants of those cities. respectively, have been quite as decided in their conviction that the same distemper is brought to them from Cape Francois, Kingston, Havana, and Demerara. Both sides are equally positive and both about equally wrong. During the 700 or 800 years since the days of the crusades these erroneous sentiments have been indulged in Christendom. Great embarrassments have been experienced from them; and at this day they seem to be increasing. It is an object worthy the attention of the national legislature, to correct within these States this growing evil.

It is apparent to your committee that most, if not all, the infectious diseases which at times afflict the crews of sea vessels arise *not* from the ports or countries they have visited but from causes which exist *within* the *vessel*. Human beings inhabiting such crowded situations engender and communicate diseases which increase in frequency and malignity by sloth and uncleanliness. Now a ship is a human habitation, and sometimes the crew is very numerous, and usually prone to grow unclean. Frequently this uncleanness accumulates to a disgusting degree and turns to poison. The poison stirs up pestilence. Arrivals from Europe have given recent and woful proofs of this.

But a ship is not merely a human dwelling; she is also a magazine or storehouse. Within her sides, as in a common receptacle, are collected many sorts of things prone to perish and corrupt.

Beef, fish, pork, hides, and other animal substances frequently taint the hold that contains them with their deleterious vapors. This tendency to putrefy is often increased by the scanty quantity and weak quality of the Liverpool salt with which they are put up. Their provision spoiling during the West India voyages, and rotting on shipboard (which is a well-known case in hot climates), render the berths and quarters of the men unhealthy, the crew sickens from the operations of such mischievous agents, and some of them are soon destroyed. The evil is increased when they are obliged to feed on such tainted or spoiled meat as a part of a daily ration. Not only animal substances, but onions, coffee, Indian corn, and various other vegetables, which are transported from country to country, contribute, by their occasional decay, to render unhealthy the bottoms in which they are carried. From these causes it is well known that provisions carried between our ports and the southern islands degenerate, and frequently the vessels conveying them are found in a very filthy and unclean condition. From the corruption of their cargoes and the uncleanness of the crews, ships may be filled with a venomous atmosphere, and the timbers, planks, bedding, etc., be charged or impregnated with the inbred mischief. Many ships belonging to the United States afford instructive examples of fevers caused on board by the exhalations from putrid provisions on their outward-bound voyages. A corrupting barrel of beef has done great injury within a vessel sailing from Great Britain to the United States.

It is a remarkable fact that ships and vessels, though so prone to become foul and pestilential, are seldom cleansed in so complete a manner as they ought to be. From the time that they are launched to the day of their condemnation few or none of them are perfectly purified. Year after year this foulness increases, insomuch that old ships and vessels are usually the most nasty and loathsome of human habitations.

Ships being thus, from their structure, tenants, and cargoes, peculiarly liable to accumulate poison, and being rarely or never cleared out, as they ought to be, carry that infectious matter engendered within them to all parts of the world, and by a curious and unhappy mistake the pestilence produced in one of these floating mansions has been almost always referred to the place from which she last came, though that place commonly has not had any kind of agency in the matter.

Hence, it will appear to every reflecting mind that the common mode of quarantine by detaining a foul ship at anchor will rather increase than remedy the evil intended to be guarded against. Bills of health are nugatory or deceitful; for if a clean ship sails from a sickly place a foul bill of health will not really indicate an unfavorable state of health on board, nor prove the crew to be affected with the distemper that prevails in the port she left; nor will a clean bill that the people in a pestilential vessel are in good health or that she is in a safe or fitting condition to be admitted to port. Consequently, bills of health are either useless or worse than nothing. With the Dutch, who are remarkable for clean ships, and who carry the system of purification on board their vessels to a greater extent than any other nation of Europe, quarantine is a mere form only. Pestilence can neither be bred nor continued on board the vessels of the Hollanders.

Instead of the rigorous rules of quarantine adopted in the United States, your committee are of the opinion the mischiefs intended to be guarded against thereby might be more effectually prevented by less injurious means. It is remarkable how little pains are taken to accomplish the complete and healthy purification of ships. None of the regulations which have hitherto been made direct the method of performing it or insist upon it with sufficient energy. A ship cannot be deemed wholesome or fit for a voyage merely because the hold and windows have been opened after she is unloaded, her decks washed and scraped, and the bilge-water pumped out. Nor will the smoking her out with brimstone, tar, or nitrous and muriatic vapors render her a suitable habitation to preserve the health and lives of men. As well might it be pretended that infected rooms, beds, and clothes could be purified by merely letting in the air and setting fumigating mixtures into action; when all domestic experience teaches that soap, lye, and lime are the only sure and efficacious auxiliaries in all cases of difficulty and danger.

It is a lamentable fact that, under the present quarantine regulations, in most places so little regard is paid to cleaning a fœtid and infectious ship, provided she does not transgress the rules *of the port where she happens to be*, by proceeding beyond her prescribed limits. She may, nevertheless, weigh anchor and go, in her foul condition, to *any other port or city* without the least impediment. By this miserable practice is the poison of plague, pestilence, or yellow fever produced, continued, and multiplied, by natural and necessary process on shipboard, and carried to all the places she visits; and while this dreadful custom prevails, there will not probably be an end of the rumors of imported contagion, and all the consequent terror and stagnation of business at home and of detention of ships and expense of quarantine abroad. The recent accounts of the severe quarantine of a hundred days and more imposed upon American vessels in some of the principal ports of Spain, must fill every friend of our country with regret. It amounts to an almost total prohibition of our trade with those cities, and is viewed by your committee as countenanced by false alarms and unfounded suggestions prevalent among our own citizens. In order to prevent these commercial restraints, in some degree, it is necessary to form our health laws upon more scientific principles, and to regulate our marine and naval intercourse upon maxims more accordant with the means to preserve domestic neatness and household purity on shore.

Considering the great influence of names over human thought and action, and the high importance of a correct nomenclature for legal and scientific purposes, it were to be wished that the term quarantine should be erased from the statute-books of the Union and of each particular State. Instead of ordering a vessel *to perform a quarantine*, she ought *simply to be directed to be made clean.* Such foul and infectious vessels, with sickly crews, should be prevented from coming to our cities or proceeding on any voyage in that situation. Nor is the matter so difficult of execution as many have imagined. When a vessel arrives from any foreign port, let her come to at some convenient place. If any are sick on board, let them be landed and all uncleanness put away. If she has any spoiled or putrefied provisions or merchandise on board, let them also be taken out. Then cause her to be scoured and cleaned in every part with pure water, soap, sand, alkaline, lye, lime, and other sweetening and purifying substances; after which the admission of a plenty of clean and good air will complete the work. These are the methods we use with success to cleanse our habitations on the land. They are equally applicable to habitations on the water, and it is necessary to scour the latter as frequently and as thoroughly as the former. But as individuals who own and navigate vessels are too careless or forgetful to cause them to be frequently and efficaciously cleansed, there is a necessity for public authority to interfere. This interference should be exerted to purtefy every foul and pestilential vessel that enters a port, and not keep her idly and injuriously riding at anchor. Quarantines may thus be shortened from forty days to *forty hours. Indeed, they would be nothing more than a thorough ship-cleaning.*

When the civilized world shall, with one accord, enforce the regular and exact purification of ships, there will be nothing on board to turn to pestilential or any other fever-producing agent, and all the inquiry necessary, when a vessel arrives, will be whether she is clean or dirty. As the latter is almost always the fact, she should be cleansed by public authority, and never suffered to go to sea, no more than enter a port, in a foul internal condition. There would then be no vessels afloat carrying infection with them from place to place, and the tales about contagion from foreign ports would gradually die away and cease to agitate society, as they now do, to the great detriment of our trade, and disgrace of commerce, medicine, and police.

After taking this comprehensive view of the subject, it would have been pleasing to the committee to have proposed something more in detail for the treatment of vessels arriving at the port of Alexandria, conformably to these principles, but the advanced period of the session prevents their offering more at this time to the House. They content themselves, therefore, for the present, with calling attention to this important subject and presenting for adoption, as a temporary expedient, a bill for extending the quarantine laws of Virginia to the territory of Columbia.

Yellow fever prevailed in the principal commercial centers during the years 1802, 1803, 1804 and 1805, but not with the fatality that it exhibited in 1798. During this period the discussion in regard to the importation and contagiousness of the fever was very exciting, and was participated in by the leading physicians of the time. Dr. Benjamin Rush, of Philadelphia, led the advocates of the local origin and non-contagiousness of the fever, and Dr. David Hosack, of New York, headed the opposition. The former class had the larger number of followers and exerted the greatest popular influence. The opinion became very general that yellow fever depended upon local filth, and that it was not propagated by any infectious or contagious properties. In the light of these opinions, quarantine rules and regulations were not only useless, but were unjustifiable restraints upon commerce and travel. Dr. Rush said of quarantines: "They originated in error; millions of money have been wasted by them; thousand of lives have been sacrificed by them." Potter, an equally zealous opponent of quarantines, asserted that he "anticipated the era when our government would make it a national concern; when a consular convention at least with the nations commercially connected with us, will put a period to a system which is a reflection upon our philosophical character."

Dr. Hosack, on the contrary, not only strongly advocated quarantines, but took high ground in favor of placing them under the management of the general government.

The opinions of Rush found a supporter in Mr. Jefferson, as appears from the following card written in 1807 and his annual message of 1805. The card is dated at Monticello, September 8, 1807, and was written to Mr. Crawford. It is as follows:

"Thomas Jefferson presents his compliments to Mr. Crawford, and his thanks for his Observations on Quarantines, which he has read with great pleasure. Not himself a friend to quarantines, nor having confidence in their efficacy, even if they are necessary, he sees with pleasure every effort to lessen their credit. But the theory which derives all infection and ascribes to unseen animals the effects hitherto believed to be produced by it, is, as yet, too new and unreceived to justify the public servants in resting thereon the public health, until time and further investigation shall have sanctioned it by a more general confidence."

In his annual message dated December 2, 1805, President Jefferson says:

"In taking a view of the state of our country, we, in the first place, notice the late affliction of two of our cities under the fatal fever which, in latter times, has occasionally visited our shores. Providence, in his goodness, gave it an early termination on this occasion, and lessened the number of its victims which have usually fallen before it. In the course of the several visitations of this disease, it has appeared that it is strictly local, incident to cities and on the tide-waters only, incommunicable in the country either by persons under the disease or by goods carried from diseased places; that its access is with the autumn and it disappears with the early frosts. These restrictions within narrow limits of time and space give security even to our maritime cities during three-fourths of the year, and to the country always. Although from these facts it appears unnecessary, yet, to satisfy the fear of foreign nations, and cautions on their part, not to be complained of in a danger whose limits are unknown to them, I have strictly enjoined on the officers at the head of the customs to certify with exact truth for every vessel sailing for a foreign port the state of health respecting this fever which prevails at the place from which she sails. Under every motive from character and duty to certify the truth, I have no doubt they have faithfully executed this injunction. Much real injury has, however, been sustained from a propensity to identify with this endemic, and to call by the same name fevers of very different kind, and which have been known at all times and in all countries, and never have been placed among those deemed contagious. As we advance in our knowledge of this disease, as facts develop the sources from which individuals receive it, the State authorities charged with the care of the public health, and Congress with that of the general commerce, will become able to regulate with effect their respective functions in those departments. The burdens of quarantine are felt at home as well as abroad; their efficacy merits examination. Although the health laws of the States should be found to need no present revisal by Congress, yet, commerce claims that their attention be ever awake to them".

After this period the danger from yellow fever epidemics became less and less threatening, and the National legislature was seldom appealed to for aid in its prevention, during the early part of the century.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

A few years ago, when the mastoid process was first opened for the liberation of pus contained within its walls, it was regarded as an extremely hazardous procedure, necessitating the highest skill, and unwarrantable except as a *dernier resort.*

As the anatomical and pathological bearings of the disease become better understood, the operation assumed a less formidable appearance, and the process is now opened sufficiently early to save most cases of this nature.

Intra-cranial lesions following aural affections have a somewhat similar history, but our knowledge and plans of procedure are still in a primitive condition, and not sufficiently crystallized to warrant a sense of security, when radical and positive steps appear to be indicated.

With the hope of somewhat systematizing our present knowledge of this subject, I have been to the pains of collecting the data of 169 cases bearing on the topic, and no case has been admitted to this series unless one of two circumstances has been fulfilled:

1. The patient must have had an ear difficulty,

resulting in intra-cranial trouble, death, and an autopsy; or,

2. The patient must have had an ear difficulty, resulting in intra-cranial trouble, and the intra-cranial cavity been exposed by operation.

By carefully systematizing these cases, I think a fairly comprehensive idea of the subject may be obtained.

Case 1.—Treated by Frank Allport, of Minneapolis, Minn. Mrs. C. W., aged twenty-five. At three years of age she had scarlet fever, resulting in acute purulent otitis on the left side, which subsequently became chronic. The suppuration continued up to her death. Years ago she suffered an acute exacerbation with a mastoid pain, relieved by counter-irritation over the mastoid. Since then she has had occasional ear-aches, but nothing decisive in its character until January 28, 1883. A few days previously she contracted a severe cold, centering in her ear, and accompanied by intense ear-ache.

I found a meatus almost imperforate from bony hypertrophy. Consequently, only the extreme outer portion of the canal was visible; therefore, the middle ear could be neither seen nor treated. The discharge was offensive, and evidently largely retained, owing to the hypertrophy of the meatus. There was no pain, redness or swelling of the mastoid. Pulse and temperature slightly advanced.

Rest, quiet and hot water douching were employed.

Feb. 2. The pain being worse and the meatus inflamed, the tissues lining the meatus were freely incised down to the bone. Improvement followed.

Feb. 10. The pain had been increasing, and was now excessive. It extended from the ear to the temporal and parietal regions, but did not involve the mastoid.

Feb. 13. Drs. Spring and Fulton were called in consultation. It was decided to open the mastoid. This was done Feb. 14, and large quantities of very fetid pus evacuated.

Great improvement followed. The discharge from the ear was much diminished.

Feb. 16. The pain in her head returned, and was referred principally to the frontal and parietel regions.

Feb. 22. She had a chill, during which, a sudden and free gush of pus occurred from the mastoid opening, after which she grew rapidly better.

Feb. 27. The pain recurred, and continued until March 1, when it subsided upon another free and sudden gush of pus from the mastoid opening.

March 7, the same phenomenon recurred; March 14, the severe pain returned; March 16, Drs. Spring, Fulton and myself met in consultation, and decided to enlarge and lower the mastoid opening, fearing the drainage was insufficient.

This was done March 17. In the course of the operation, a sinus was discovered within the boundaries of the mastoid opening, leading into the cerebellum. The sinus was about one-fourth of an inch wide.

March 20. Drs. Spring, Fulton, Abbott, Johnson and myself met in consultation.

March 23. Severe pain in the frontal and parietal regions appeared. In the evening she had a chill.

March 24. Some delirium. The same physicians were called in consultation. The blunt canula of an aspirating syringe was inserted into the sinus and into the cranial cavity. No pus was found. Pain, restlessness and nervousness now continued until the termination of the case.

March 28. In pressing upon the temple, it was noticed that pus was forced into the mastoid opening. A sinus was found extending over the squamous portion of the temporal bone, and terminating in the region of the zygomatic arch. The sinus was kept drained with a tube, and washed with peroxide of hydrogen.

April 2. A peaceful death.

Her pulse and temperature were never very high. Her pulse ranged from 80 to 108, and her temperature from 98½° to 103½°. It did not often exceed 101°.

Autopsy.—Drs. Spring, Fulton, Abbott, Johnson, Hill, Wells and myself being present. Extensive necrosis was found outside of the skull, extending from the outer surface of the mastoid to the squamous portion of the temporal bone, extending over the frontal bone and to the superior maxilla down below the zygomatic arch. The soft parts were separated from the bone over this entire area, and considerable quantities of pus followed the diseased tract.

We found that the sinus we had discovered in the course of the operation did, in fact, open into the cerebellum through the inner mastoid plate, but no pus had accumulated at this region.

The outer portion of the squamous portion of the temporal bone was almost entirely destroyed by necrosis. No fluctuation, redness or swelling indicated this before death. A large opening existed in the squamous bone, connecting directly with the cranial cavity. The external diffused abscess at this point extended from the entire squamous portion of the temporal bone down to below the zygoma, and as far forward as two inches in front of the ear. Extending over this territory, the soft parts were completely lifted from the bones, which were generally blackened from necrosis.

The inner surface of the temporal bone was badly necrosed, especially at four points—1, the squamous portion; 2, the upper part of the petrous portion; 3, the petrous portion corresponding to the middle and internal ears; and 4, the inner plate of the mastoid. The petrous bone was so softened in many places as to be easily scraped up like so much wet sand. A large, carious opening connected the middle and internal ears and the cranial cavity. An opening existed through the mastoid, just in front of the lateral sinus.

There was a general injection of the entire brain tissue, especially in the tempero-sphenoidal lobe. The left side of the brain was much flattened, and the resulting space filled up with pus.

Pus deposits were also found in the first frontal fissure, in the first frontal convolution, in the fissure of Rolando, in the middle lobe on the right side, and in both lateral ventricles.

There were enormous pus deposits in the region of the medulla and pons.

The cerebellum was much softened by purulent infiltration, and pus was found in its interior.

The patient's mental functions were practically unimpaired up to the time of her death.

Case 2.—Treated by Frank Allport, of Minneapolis, Minn. N. N., male, age twenty-three. Right ear. Acute purulent inflammation of the middle ear.

Was brought to the City Hospital September 16,

1889. Dr. Chase requested me to see him. There was pain in the ear and side of the head. Tenderness over the mastoid, but no swelling. Clouded intelligence. Pulse 64; temperature $103\frac{3}{5}$. Calomel and morphia were administered, and the ear frequently douched with hot water.

Sept. 17. The mastoid cells were opened, but no pus was found. The cells, however, were much softened and broken down, and a probe could be passed through the inner plate of the mastoid into the cranial cavity. This was enlarged, but no pus was found.

It was determined to trephine the skull at another point, as it was evident that pus existed somewhere in the cranial cavity, owing to the profound cerebral symptoms, the carious opening through the inner mastoid plate, and the lack of pus in the mastoid cells. The directions of Barr were followed, and the opening made through the squamous portion of the temporal bone, just above the auricle. No pus was found. Another was then made back of the auricle, and involving both the mastoid and occipital bone. A small amount of pus was here found. The wounds were irrigated and dressed antiseptically. He died that evening. His pulse was always slow, and his temperature never extended above $103\frac{3}{5}°$, and the morning of the operation it was subnormal. No evidence of any paralysis was observed in the case.

Autopsy.—This was made by Prof. W. A. Jones, Dr. Chase and myself. The dura-mater was adherent. There was a blood clot in the longitudinal sinus, and over the Sylvian fissure. Clotted blood extended over the parietal lobe backward to the occipital lobe. A large blood clot envelopes the temporal and sphenoidal lobes. A clot is found in the superior petrosal sinus, and in the right ventricle.

The right hemisphere is deeply congested; the left hemisphere slightly congested.

The medulla was bathed in pus. Abscess, and purulent meningitis of cerebellum.

There are carious openings through the petrous portion of the temporal bone connecting the cranial cavity with the middle and internal ears. A carious opening is found extending through the internal mastoid plate.

Case 3.—Treated by Frank Allport, of Minneapolis, Minn. F. J., male, age twenty-two. City Hospital case. Last June he had a fever, followed by an abscess of the right middle ear.

He came to my clinic at the University Dispensary, October 2, 1888, with a large mastoid swelling. This was opened and pus evacuated. I found a spontaneous opening through the external mastoid plate, which was enlarged. Pus was located in the cells. His pulse and temperature was somewhat heightened.

He went on to an uninterrupted recovery. January 25 he returned to the hospital with typhoid fever, and was treated by Prof. Dunn, the city physician. He died.

Autopsy by Prof. Jones;Prof. Dunn and myself. We found a venous congestion of the meninges. A thrombus was found in the posterior portion of the longitudinal sinus. Another thrombus was found in the lateral sinus. The dura-mater over the internal plate of the mastoid was much thickened and bound down by adhesions. The inner plate of the mastoid was thickened, darkened, porous and hard. The walls of the mastoid cells were hypertrophied. The cells were few in number.

The opening made in external plate was refilled with bony cicatricial tissue. The abdominal examination showed death by typhoid fever.

Case 4.—Treated by Frank Allport, of Minneapolis, Minn. J. M., male, age thirty-four. I was called to see him April 30, 1889, by Drs. Sweetzer and Hall.

I found him with a discharge from the right ear, with an accompanying acute inflammation. He has had chronic otorrhœa for a long time. He had pyæmic abscesses in various parts of his body. Temperature from 102 to 105; pulse averages about 140°. Is having chills. Has no paralytic symptoms. Has great pain in his head, but this disappeared several days before death. Mentality good, but is very nervous and excitable. Became unconscious just before death, but not before. He had no mastoid symptoms. He died May 2.

Autopsy by Drs. Sweetzer, Hall and myself. The mastoid was unaffected. The middle ear was carious, and the ossicles had all disappeared. There was no carious connection between the mastoid, middle or internal ears, and the cranial cavity. We found a thrombus in the superior petrosal sinus, pus in the superior petrosal and lateral sinuses, necrosis in the lateral sinus and general meningitis

Case 5.—Treated by Frank Allport, of Minneapolis, Minn. J. F., male, age twenty-five. Was struck in the right ear while boxing. Came to the City Hospital Nov. 29. An examination of the ear, at the request of Dr. Dunn, disclosed some inspissated cerumen, which was removed. The drum-head was much inflamed and swollen. Hearing good. Drum-head lanced and pus evacuated. The hot douche was frequently used, and the patient kept in bed. He improved.

In about one week, after considerable pain in the ear and mastoid, a swelling appeared over the mastoid, accompanied by tenderness and some pain in the temporal and parietal regions. The discharge continued.

Dec. 10. The mastoid cells were opened, and pus liberated. Improvement followed until January 11, when the pain in the right side of the head reappeared, accompanied by slight pain and swelling in the neck, extending down from the mastoid process. These neck symptoms entirely disappeared in a few days. The bowels were loose.

Jan. 15. The mastoid opening was enlarged and improvement followed.

Jan. 29. Pain in the right side of the head again. Vomiting and delirium. Improvement until Feb. 10, when the pain reappeared. Delirium; coma and death.

He never had any paralytic symptoms. The temperature and pulse were never high, and the temperature was often sub-normal.

Autopsy by Prof. Hendricks Prof. Dunn and myself. There was a diffuse sub-dural abscess, most marked in the anterior parietal region anterior to the fissure of Rolando. A purulent thrombus existed in the superior longitudinal sinus. Firm adhesion existed between the arachnoid and pia-mater. There was pus on the surface of the right frontal convolution and the right temporal convolution. A small thrombus existed in the lateral sinus. There was a carious opening from the mastoid cells into the lateral sinus. The petrous bone was unaffected, with the exception of the purulent inflammation of the middle ear.

(*To be continued.*)

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1271, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1274, Philadelphia, Pa., sending him a certificate or statement that he *is in good standing in his* own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 15, 1892.

THE PRESENT STATUS OF THE TREATMENT OF CONGENITAL CLUB-FOOT.

Nineteen papers on club-foot, followed by an extended discussion, chiefly occupied the American Orthopedic Association at its recent meeting in New York. We will attempt to summarize these deliberations.

In congenital club-foot there is a shortening of all tissues, bony, ligamentous, muscular, tendinous, fibrous and cutaneous, on the side to which the deformity looks. In certain cases the deformity can be corrected without resort to a cutting operation; in others not. In the child with growing bones, if the foot can be continuously maintained in the corrected position for a sufficiently long time, the bony and soft parts adapt themselves to the changed position and a permanent cure may result, but in the older foot, even if the deformity can be corrected by non-operative means, a perfect and permanent result may not be anticipated unless a bone operation be made which will restore the articular surfaces to their normal outlook. The milder measures are always to be resorted to in the treatment before resorting to the more severe ones, unless the age of the patient and the severity of the deformity render the milder measures obviously useless.

The treatment is divided into two stages: 1, the corrective; and 2, the retentive. Correction of the deformity is accomplished by frequently repeated or continuous stretching, or at once by *brisement forcé*, or by a cutting operation, or by both. Retentive appliances completely immobilize, or permit of motion in the directions the opposite of the late deformity. Treatment should be commenced at the earliest possible moment. In young children the hand of the operator is the most convenient means for frequently repeated stretchings, and in some cases is sufficient for immediate forcible correction of the deformity. Various mechanical devices are also employed for stretching the foot into shape, most of them being modifications of SCARPA's shoe, and acting both as stretching and retentive appliances. A more forcible instrument is found in the THOMAS wrench, used to stretch the foot past the point of resiliency, when it can be readily retained in a simple brace. Still more forcible means are found in the devices of MORTON, BRADFORD and PHELPS, but these are used almost exclusively in connection with some cutting operation. The simpler operations are the subcutaneous divisions of the tendons, of the fasciæ and of the ligaments. When the subcutaneous division of all possible of the shortened tissues and the forcible use of the wrench fails, all the soft parts on the concave side should be divided by an open operation, and the wrench or machine again applied to stretch or crush the foot into shape. Failing in this an incision is made at the outer side of the foot, and a linear or a cuneiform osteotomy is made just posterior to the anterior articular surface of the os calcis, and if necessary also of the neck of the astragalus, and again the machine is used to forcibly correct the deformity. In a few cases it will be necessary to excise the astragalus, but this will only be required when the bone is displaced far forward and the tibia articulates with the os calcis. Treatment should be carried persistently forward until a perfect and permanent cure has been attained. The guide for perfect correction of the deformity is found in the median line of the sole. In the varus foot, the median line of the sole of the anterior portion of the foot meets the median line of the sole of the heel to form an angle; in the normal foot they meet to form a straight line. The certainty of a permanent result can only be told by a knowledge that the articular surfaces look in the normal direction, or from the results of use freed from retentive apparatus. In a word, treatment is commenced as early as possible by the employment of simpler methods and milder means, and is carried on step by step in accordance with the indications until a real cure, a restoration to normal contour and perfect function, has been attained.

A NATIONAL QUARANTINE LAW.

The series of papers which have appeared in THE JOURNAL reviewing the history of the quarantine in Congress in the first years of the republic, have a special importance at this time. We are doubtless on the eve of a renewal of the agitation in favor of a more rational and effective quarantine system for this country, and the proposition to create a national quarantine will be more earnestly advocated than at any former period. In this view the first discussion of the subject in Congress will prove interesting and profitable. The fact that there was so decided a movement in the first sessions of Congress to call upon the general government to aid in preventing the introduction and spread of contagious diseases, is in itself of importance. It proves that there was at the organization of the government a party which maintained that its powers extended to the control of the quarantine of all vessels from foreign ports or places, and "to direct at what place or station," and "for what duration and particular periods of time," such vessels should perform quarantine.

The discussions which followed the introduction of the bill to empower the President to direct quarantine are interesting, as showing that the division of opinion, as to the powers of the general government and the rights of the States, was neither sectional nor partisan. The bill was introduced by a member from Maryland, and one of the most effective arguments in its favor was made by a member from South Carolina. He pertinently said, "Consider how epidemical diseases, imported, affect the United States at large; they do not merely affect the city where first imported, but they obstruct the commerce of all others." "It had been said that this subject could be better considered in each individual State than we could possibly settle it. Who are we? Are we a foreign government?" "If the subject was vested in the general government it was their business to protect the health of their fellow citizens as much as their property; because if the performance of quarantine was neglected such neglect naturally tended to affect the lives as well as the revenues and commerce of the citizens throughout the United States. He, therefore, thought it a subject perfectly within the Federal jurisdiction." The most strenuous opposition to the bill came from a member from Massachusetts, who vigorously maintained the "State rights" doctrine. It is not a little surprising, considering the intense feeling that at this early period existed against Federal encroachments upon State powers and rights, that on the final vote one-third of the members were recorded in favor of a national quarantine.

The frequent outbreaks of yellow fever in succeeding years, owing to our active commerce with the West Indies. occasionally renewed the agitation of quarantine in Congress. The most notable incident in this agitation was the report of Dr. Samuel L. Mitchell, a member from New York City, in 1803. This report we have printed at length as, perhaps, the most remarkable contribution to the subject of the prevention of the spread of contagious diseases by ships, ever put on record. Dr. Mitchell was a man of vast erudition, of an inquisitive mind and of a controversial habit. He embraced in the range of his studies all of the natural sciences, but chemistry was his favorite field of inquiry. In investigating the origin of contagious diseases he came to attach great importance to the ferments, and from them evolved the septic agent which caused various diseases. This was his *septon*. In these speculations he was treading upon grounds made familiar to us, in these latter days, by Lister and others. The great remedy for the septon of Mitchell was potash in the form of soap or lye. Cleanliness by means of these agents was, in his opinion, a sure preventive against contagious and infectious diseases His comparison of an inhabited ship to an inhabited house is very happy, and his insistences that the former can and should be made and kept as clean as the latter, and by the same means, viz., scrubbing with soap and lye, is a lesson in ship sanitation which, if practically enforced, would, as he alleges, reduce the regulation quarantine time from forty days to forty hours.

Though the question of a national quarantine was scarcely revived in Congress until within the last few years, yet it is now likely to become one of the "burning questions" of the next session.

JACQUES INAUDI, A MODERN PRODIGY.

A shepherd lad, bearing the above name, has occupied a liberal share of the scientific attention of Paris during the past few months. He has been under investigation by the French Academy, by the Sorboune and at the Salpêtrière, the verdict being that he is one of the first calculators of the century. Alfred Binet, in *Revue des Deux Mondes*, gives an interesting summary of examinations made by himself and Dr. Charcot. Although spoken of as "the Piedmontese shepherd lad" Inaudi is now twenty-four years of age. He is short and stout and has a large cranium. The young man is intelligent, converses with spirit, plays games with skill, and is much more than a mere calculating machine. A protracted anthropometric examination by Charcot shows a few insignificant signs of degeneration.

Inaudi did not learn to read and write until he was twenty years old. Yet when only twelve he was a prodigy in calculating. He began to combine numbers as early as when he was six years old; while watching his sheep he worked out arithmetical problems by methods original to himself. In addition, he will add seven numbers of eight or ten figures each, beginning at the left. In subtraction, he deals readily with numbers containing twenty figures; here, also, he begins at the left. He can multiply two numbers composed of eight figures; or give the total number of seconds in any given number of years, months, days, and hours. He was, on one occasion, asked the number of seconds in 18 years, 7 months, 21 days, and 3 hours. The answer was ready in thirteen seconds. He obtains the sixth or seventh root of large numbers with astonishing rapidity. Although he has learned the ordinary methods of calculation, he is said not to use them.

CHARCOT caused him to perform, at the Salpêtrière, two equally difficult problems in division, one upon paper according to the usual method, the other in his head, after his own process; the former required thrice as long to perform as the latter. He can repeat a number containing thirty figures, orally given him, and retain it clearly in his memory for some time. On one occasion, he remembered a number containing 22 figures for a week, although he had no warning that he would be asked for it again. His memory is not remarkable in any other direction than in that for numbers. The playing of chess blindfold is to him a complete enigma. His memory for melody, form, place and color is rather inferior to the average.

Of the mental attitude of INAUDI toward his remarkable powers, it is interesting to note that audition and not vision, is the channel of his work. This is contrary to the experience of COLBURN, MONDEUX, and all former prodigies in numbers, who have been able to explain their methods. Visualization has been the rule in all other cases. The committee of the Acadèmie des Sciences, in their report, say "he calculates with greater ease when the problem is put to him by word of mouth than when placed before him in writing; the sight of figures embarrasses him, and reverting to the procedure natural to him, he repeats to himself, either aloud or in a low voice, the numbers that he wishes to remember."

BINET's inquiry concerning any influence of heredity in the production of INAUDI's remarkable gift returned to him unsatisfied. The young man's parentage was lowly, and his ancestors were not known to have had any marked peculiarities. No other relative has manifested any calculating ability; his brothers tried to learn from him, but without success. He had not had any derangement of health as a youth, and his growth was in every way like that of his fellow peasant lads. He was simply seized with a passion for reckoning, or for the exercise of his memorizing faculty. The Academic investigators acknowledged a negative result in the heredity branch of their inquiry.

The case of this young man seems to establish the perfectibility of human faculties many times beyond the normal, and as BINET says "this fact is especially important to us because it allows us to see the high degree of elevation the mind of man may yet attain."

THE MISSION HOSPITAL AT CANTON.

This institution was opened in 1839 by DR. PETER PARKER. It is now conducted by DR. J. G. KERR. assisted by DR. J. M. SWAN and MISS NILES, M.D. During 1891, the number of patients received was 1,269, while there were treated in the out patient department not less than 22,000 cases. There were 2,140 surgical operations performed. The wards are roomy and improvements are added yearly. About thirty natives have been trained in four year courses. Some of these continue at Canton and assist at the Canton Hospital or at the three dispensaries conducted by DR. MARY FULTON, at which several thousand women and children have received treatment. Others of the graduates have gone back to their former homes into the interior and even to the borders of riotous Hunan. Nearly all the high officials of Canton have from time to time had occasion to seek the advice of our American medical missionaries, and the latter have had large measure of success. On one occasion, not long ago, DR. KERR was invited to attend the Tartar General who was the military commandant of the city and district. After his recovery this official came with a large retinue to express his grateful appreciation to the physician. The pomp and circumstance of this visit was the means of producing a profound impression among the people—deeper perhaps than would have been made by successful services on a hundred persons of minor rank. The influence of the Hospital is extended to the island of Nodoa, DR. H. M. MCCANDLISS and an assistant, there being a small pioneer hospital at the town of Nodoa.

ELEVENTH INTERNATIONAL CONGRESS.

As a recent notice in this JOURNAL has informed our readers, the Eleventh International Congress will meet in Rome, Italy, from September 24 to October 1, 1893. By an official letter dated August 22, 1892, and signed by Prof. Guido Baccelli, President, and Prof. E. Maragliano, Secretary General, Dr. A. Jacobi, of New York, has been directed to form an American Subcommittee. Its membership is not yet complete, but on it are already found beside that of the Chairman, the names of Drs. Wm. Osler of Baltimore, S. C. Busey of Washington, N. S. Davis of Chicago, Charles A. L. Reed of Cincinnati, Wm. Pepper of Philadelphia, F. Peyre Porcher of Charleston, James Stewart of Montreal, and Alexander J. C. Skene of Brooklyn, N. Y. In the interest of facilitating the trip to Italy, and reducing the expense, arrangements will be made with the Steamship Companies. According to a communication from the Central Committee—contained in a letter of the Secretary General's dated September 14, the North German Lloyd proposes to reduce the fare to Genoa by twenty per cent., and that of the return trip by ten per cent. It is expected that still more favorable terms will be secured.

UNIVERSITY OF MONTREAL.—The chair of pathology in this institution has been offered to Dr. Adami, fellow of Jesus College, Cambridge University, and formerly of Owens College, Manchester. The University has a pathological laboratory ready for students and practitioners wishing to do special work in bacteriology and morbid anatomy.

THE ENGLISH DISEASE.—The natives of Damascus are said to have been obliged to find a new name for drunkenness, and inasmuch as a large proportion of its victims are foreigners or tourists, they have called it "the English disease."

A NEW ABORTIFACIENT.—At a recent coroner's inquest at Leicester, England, testimony was adduced to show that the deceased, a woman, had been in the habit of purchasing diachylon in the lump and eating it to produce abortion. The experiment was generally successful in her case, it was alleged, but she tried it once too often, and died from an overdose of lead.

DOMESTIC CORRESPONDENCE.

To the Editor of the JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION:

Please give publicity through your JOURNAL to a confidence game that is being worked on physicians in this State and probably in others. A "special agent" sailing under the name of F. C. Washburn, of St. Paul, Minn., goes from city to city appointing medical examiners for the Bankers' Mutual Aid Association of St. Paul, Minn. The examiner is naturally requested to take a policy for which he pays $5.00 quarterly dues in advance. No policy ever appears and the appointment is bogus. Yours very truly,

F. LOHRSTORFER, M.D.

Port Huron, Mich., Oct. 8, 1892.

NECROLOGY.

MR. WILLIAM D. HUSBAND, M.R.C.S., a former president of the British Medical Association, died at York, July 18, in his 76th year. He was for many years the treasurer of that Association, and seldom failed in a half century of membership to attend the meetings. He was the leading surgeon of the West Riding of Yorkshire, and was senior attendant to the County Hospital and the Retreat. He was Lord Mayor and Justice of the city. He had been lecturer on clinical surgery in the York School of Medicine.

DR. JOHN H. DOUGLAS, formerly of New York City, died in Washington, D. C., October 2, aged 68 years. He was a native of Waterford, N. Y., and graduated at the University of Pennsylvania in 1847. He was a resident of New York, during the greater part of his professional life, engaged in a specialty of diseases of the throat and lungs. He was General Grant's physician during the last painful illness of that eminent American. Dr. Douglas was unremitting in his services, and found it expedient, after the death of the General, to go to Mexico on a recruiting excursion. He went to Cuba and Florida also, but he seems not to have been benefited by the southern climatic influences. His health was still further broken about two years ago by a cerebral hæmorrhage, and a second stroke was experienced by him in Washington, about a fortnight ago. An unpleasant discrepancy, some of the discussion of which was worked over in the newspapers, arose between the survivors of the General and Dr. Douglas regarding the latter's fees. This was arranged, if not placated, by the payment of about $12,000 for services covering the greater part of ten months. Some of these services were exclusive, the class of all others concerning which there is the greatest room for disagreements and subsequent litigation. The last four years of Dr. Douglas' life were spent in retirement, chiefly in the vicinity of New York and in Washington. Without doubt under some forms of Government, having more of gratitude than Republics, Dr. Douglas would have been, in his latter days, in the receipt of a comfortable pension.

MISCELLANY.

WE hear the S. S. S. man of Atlanta has gone on a visit to Hot Springs, Arkansas, for his "rheumatism."—*Atlanta Med. Journal.*

The Chicago Clinical Review is the latest candidate for professional favor. Drs. Cleveland and Bouffleur are the editors.

MEETING OF INTERNATIONAL MEDICAL CONGRESS (American Public Health Association), in the City of Mexico, November 29th and 30th and December 1st and 2nd, 1892. For the convenience of delegates, and all physicians with their families, who desire to attend this meeting, an elegant Pullman car will leave Chicago November 19th. Short stops will be made at all points of interest between Chicago and the City of Mexico. For further information, maps, time tables, etc., address John E. Ennis, D. P. A., Mo. Pac. Ry., 199 Clark street, Chicago, Ill.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from October 1, 1892, to October 7, 1892.

Major Alfred A. Woodhull, Surgeon U. S. A., leave of absence granted is extended ten days.

Capt. Junius L. Powell, Asst. Surgeon U. S. A., is relieved from duty at Ft. Randall, S. Dak., to take effect upon the final abandonment of that post, and will then repair to Ft. Monroe, Va., and report in person to the commanding officer of that post for duty.

Major Robert M. O'Reilly, Surgeon U. S. A., will be relieved from duty at Ft. Logan, Col., and will report for duty as Attending Surgeon in this city on December 15, 1892.

Lieut.-Col. Francis L. Town, Deputy Surgeon-General U. S. A., is relieved from duty at the Presidio of San Francisco, Cal., and will report in person to the commanding officer, Ft. Porter, N. Y., for duty at that station.

Capt. Alonzo R. Chapin, Asst. Surgeon U. S. A., is relieved from duty at Ft. Yates, N. Dak., and will report in person to the commanding officer, Ft. Hancock, Tex., for duty at that station.

Capt. Eugene L. Swift, Asst. Surgeon U. S. A., is relieved from duty at Ft. Grant, Ariz., and will report in person to the commanding officer, Ft. Yates, N. Dak., for duty at that station.

Major Egon A. Koerper, Surgeon U. S. A., is relieved from duty at Ft. Walla Walla, Wash., and will report in person to the commanding officer, Willet's Point, N. Y., for duty at that station, relieving Major Clarence Ewen, Surgeon. Major Ewen, on being relieved by Major Koerper, will report in person to the commanding officer, Ft. Walla Walla, Wash., for duty at that station.

Major Robert H. White, Surgeon U. S. A., granted leave of absence for two months, to take effect during October, 1892.

Capt. Edgar A. Mearns, Asst. Surgeon U. S. A., is relieved from further duty with the commission appointed for the location and marking of the boundary between Mexico and the United States, and will without delay proceed from El Paso, Tex., to Ft. Clark, Tex., and report in person for duty to the commanding officer of that post.

OFFICIAL LIST OF CHANGES in the Medical Corps of the U. S. Navy, for the Week Ending October 1, 1892.

P. A. Surgeon Eugene P. Stone, detached from the "Pinta," and granted two months' leave.

P. A. Surgeon Louis W. Atlee, detached from the "Independence," and ordered to the "Pinta."

P. A. Surgeon F. N. Ogden, detached from duty in connection with Inter-Continental Railway Commission, and to the "Independence."

Surgeon William Martin, detached from the "Thetis."

P. A. Surgeon Chas. N. Rush, detached from the Navy Yard, New York, and granted six months' sick leave.

ORIGINAL ARTICLES.

REPORT OF CASE OF PAPILLOMA OF THE LARYNX—INTUBATION TUBE WORN *FOUR YEARS.*

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, heald at Detroit, Mich., June, 1892.

BY F. E. WAXHAM, M.D.,

PROF. OF LARYNGOLOGY, RHINOLOGY AND DISEASES OF CHILDREN, COLLEGE OF PHYSICIANS AND SURGEONS OF CHICAGO.

Papillomata of the larynx, while classified among the non-malignant growths, are nevertheless of the gravest import when occurring in early life and especially in very young children.

The case coming under my observation is unique on account of the complications, the length of time the laryngeal tube has been worn, and the almost perfect comfort of the patient. The child has worn the tube since he was two and a half years old and is well developed, strong and healthy and does not complain of pain or irritation of the larynx as the result of its presence. Indeed much less discomfort is experienced than results from the presence of a tracheotomy tube.

June 17, 1888, I was called through the courtesy of Dr. J. S. Mitchel to see Arthur D., age two and one half years. His breathing was labored, the voice whispering, and the dyspnœa so great that the loud stridor was heard all over the room. Notwithstanding the difficulty of breathing he was busy and playful. The following history was obtained: His voice and cry were natural until an attack of measles which occurred at the age of one and a half years. During the attack of measles he coughed croupy and breathed with some difficulty but these symptoms disappeared. The voice had been husky for eight months and entirely suppressed for two months. The respiration had been more or less embarrassed for two months. The dyspnœa gradually increased. For three days the child had been breathing with great difficulty. The patient had been seen by a number of physicians, including the late Dr. H. A. Johnson, all of whom pronounced the case one of laryngeal obstruction due to papilloma!

As the color of the patient seemed good and as he was playing about it was thought safe to postpone operative measures for a few hours and to watch the case. Later in the day we were again called and found a decided change for the worse. The little fellow had become prostrated by the difficulty of breathing, the pulse had become rapid and feeble, and he was slowly dying from suffocation. It was decided to perform intubation with the hope that the introduction of the tube and subsequent pressure might destroy the growth. The operation was quickly and easily done, giving immediate relief and the patient passed into a quiet refreshing sleep. The next morning he was found riding his velocipede about the house and suffering no inconvenience from the tube. The tube was worn for six days without the least annoyance.

On the sixth day the tube was removed. The respiration was quite difficult for a few hours following its extraction. The dyspnœa, however, soon subsided and the respiration remained about as it was during the weeks preceding the urgent symptoms that led to the operation. The voice still remained suppressed and the respiration somewhat embarrassed for two weeks but not sufficiently so as to call for interference.

July 9. The urgent dyspnœa returned and it became necessary to re-introduce the tube which again gave immediate relief.

July 12. Removed the tube but the patient could not live without it. It was apparent that the simple pressure of the tube was not sufficient to destroy the growth. The upper and anterior portion of the tube was discolored showing the location of the greatest pressure. This portion of the tube was coated with collodion, this in turn with chromic acid and then another coating of collodion and the tube introduced, the idea being to destroy the growth by cauterization, as on account of the early age of the patient a laryngeal examination was impossible and the removal of the growth by the intralaryngeal method not practical. As laryngotomy at so early an age was extremely hazardous and in the great majority of cases very unsatisfactory, cauterization in this manner seemed worthy of a trial.

July 15. The tube was again removed and as the dyspnœa was great another application of chromic acid was made. On account of a previously arranged trip to Europe the case was placed in the hands of another physician. The tube was left in position for ten days when on account of some difficulty in removing it tracheotomy was performed. About this time the child contracted whooping cough which with a very severe diarrhœa, which possibly resulted from the constitutional effect of the chromic acid, greatly prostrated him. Under very skilful treatment, however, the patient soon rallied and was about the house again.

Oct. 1. Upon my return from Europe the patient was found in a very good condition but wearing a tracheotomy tube instead of the intubation tube.

Oct. 8. Gave the patient chloroform and made an examination of the larynx with the finger and laryngeal sound. The larynx was entirely closed on account of adhesions that had formed as the result of cauterization. The smallest laryngeal sound could not be passed and no air could be drawn through it when the tracheotomy canula was closed with the finger.

Oct. 14. With the assistance of Drs. Ingals and Jaggard of Chicago, Dr. Guibar, of Kansas, and Dr. King of Iowa, chloroform was given and laryngotomy performed. The adhesions were broken up and cut away as far as possible and portions of the papilloma still remaining removed and the surface thoroughly cauterized with nitrate of silver. The cartilages of the larynx were united with silver wire sutures, the wound dressed antiseptically and the tracheotomy tube left in position.

Oct. 21. Gave the patient chloroform and examined the larynx carefully. It was found nearly closed again. Only a very small laryngeal sound could be passed. This was introduced and the adhesions broken up as far as possible and the smallest size intubation tube introduced, which was left in position above the tracheotomy tube.

Oct. 28. The intubation tube removed and also the silver wire sutures.

Nov. 4. The wound entirely healed. The intubation tube was reintroduced, the patient wearing both the tracheotomy and intubation tubes with comfort, being able to eat and even to drink liquids in the upright position without difficulty.

Nov. 11. Removed the intubation tube and introduced a larger one.

Nov. 18. Removed the intubation tube and introduced a still larger one, shortened so as to be worn above the tracheotomy tube. Strangely enough the patient could not breathe through the intubation tube excepting with great difficulty and the tracheotomy tube was still worn.

Dec. 2. With the assistance of Dr. Ingals chloroform was again given and a careful examination of the larynx made. The papilloma seemed to be reappearing about the base of the epiglottis which upon inspiration was drawn down over the opening of the tube, thus preventing respiration through it.

Dec. 8. With the assistance of Dr. Hawk, of Iowa, chloroform was administered and the growth at the upper portion of the larynx removed with a curette. A tracheotomy tube with an opening in the outer canula was also introduced.

Dec. 11. He was able to breathe quite comfortably through the intubation tube with a cork in the tracheotomy tube.

It is unnecessary to detail the further history of the case. There has been a constant tendency to recurrence of granulation tissue above the head of the intubation tube requiring frequent operations. The intubation tube was changed on an average of once a month, its diameter being gradually increased. The tracheotomy tube was removed and cleansed daily by the attendants. After wearing both intubation and tracheotomy tubes for two years the latter was dispensed with and the intubation tube increased both in length and diameter. For the last two years the intubation tube alone has been worn. The patient at times wearing it as long as two months without changing. The head of the tube is occasionally altered in shape in order to prevent too long continued pressure upon one point. The patient is now able to do without his tube a few hours at a time. The boy is now six and a half years old and as strong and rugged as any boy of his age. We are hopeful that as he reaches puberty and as the larynx increases in size at this age there will be sufficient room for normal repiration notwithstanding the amount of cicatricial tissue present.

240 Wabash Avenue.

Discussion.

Dr. Wigler called attention to the late paper of Dr. Hooper, of Boston, in which he described endo-laryngeal operations under chloroform in children. He also referred to an instrument lately devised by Dionisio, an endo-laryngeal speculum which holds the glottis open in the living subject.

Dr. Thrasher said that he was much interested in the paper of Dr. Waxham. About a year ago a 6 year old boy was brought to him suffering from dyspnœa. Examination revealed the chink of glottis blocked by a red granular mass, apparently papillomata. After a preliminary tracheotomy the larynx was pretty well cleared by the cutting forceps and when the respiration per *vias naturales* was restored (in about 3 weeks) the patient went home. In about 2 months he returned with an increased growth of the neoplasm. These were removed under cocaine at one sitting and the patient was not seen again for a month when the operation was again repeated. The recurring growths were removed at intervals of 4 to 8 weeks until January 1, of this year. At that time the dyspnœa was not sufficiently relieved by the attempted removal of the warty tissue and a small intubation tube was inserted to permit of the child's returning home. This tube was worn about a month and brought back in the hand of the patient, having been coughed out. Dr. T. then re-inserted a larger tube and the patient has worn a tube ever since. Some 3 weeks ago Dr. T. learned that the little fellow had taken whooping cough but was getting along as well as could be expected. There was a marked atrophy of the sessile growths, apparently from the pressure of the tube, after the tube had been worn for only a month, and this atrophy gradually continued up to the time of the invasion of the whooping cough, since when the patient has not been seen.

Dr. Von Klein remarked that he had been called in the night to see a case of dyspnœa from papillomatous obstruction. He attempted to introduce an intubation tube, failed, tried a smaller and found that there was not room to pass the smallest size tube. He then advised tracheotomy but parents objected and soon the child died of CO_2 poisoning.

Hæmorrhoids rapidly diminish in size, become free from secretion and pain, and generally improve, according to Dr. James, if powdered daily with pure calomel.

SPONTANEOUS CURE OF MULTIPLE PAPILLOMATA OF THE LARYNX AFTER TRACHEOTOMY.

SAME CASE ALSO DEVELOPED THE RARE ANOMALY OF PAPILLOMA OF THE EPIGLOTTIS.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY JOSEPH A. WHITE, A.M., M.D.,
SENIOR SURGEON TO THE RICHMOND, VA., EYE, EAR, THROAT AND NOSE INFIRMARY.

Frank Bigby, aged 5 years, was brought to me on June 11, 1886, suffering with dysphonia and severe attacks of dyspnœa. I had no difficulty in making a laryngoscopic examination, and found his trouble was due to the presence of several small growths of the larynx, located especially on the left cord and ventricular band near the commissure, and also at the inter-arytenoid space. After two or three sittings to accustom the larynx to the contact of the forceps, I succeeded in removing the obstructions and cauterizing their seats with chromic acid. In October he was brought back because of the return of dyspnœa, and I found the growths had not only recurred, but also had extended to the right side. I also noticed a small protuberance on the lower face of the epiglottis on the right side as if a similar neoplasm were developing there. October 10, I operated with the forceps, removing most of the growths. November 14, he came back with a more decided recurrence, a regular cauliflower mass, and with the protuberance on the epiglottis developed into a small pediculated tumor. I again removed all the growths, and fearing they might be malignant, I sent one specimen to Dr. Wm. M. Gray, the pathologist of the Army Medical Museum in Washington, and another to Dr. Geo. Lefferts, of New York. The former replied that the growth was a hard papilloma, composed of squamous epithelial cells, and histeoid in character. Dr. Lefferts answered November 16, 1886, that the growth was a papilloma, and that there was no reason why it should not be radically extirpated, although he did not think this could be done per *vias naturales* in a child only 5 years of age, and suggested thyrotomy as the best means to that end. He added, "I have never seen, heard or read of a papilloma of the epiglottis".

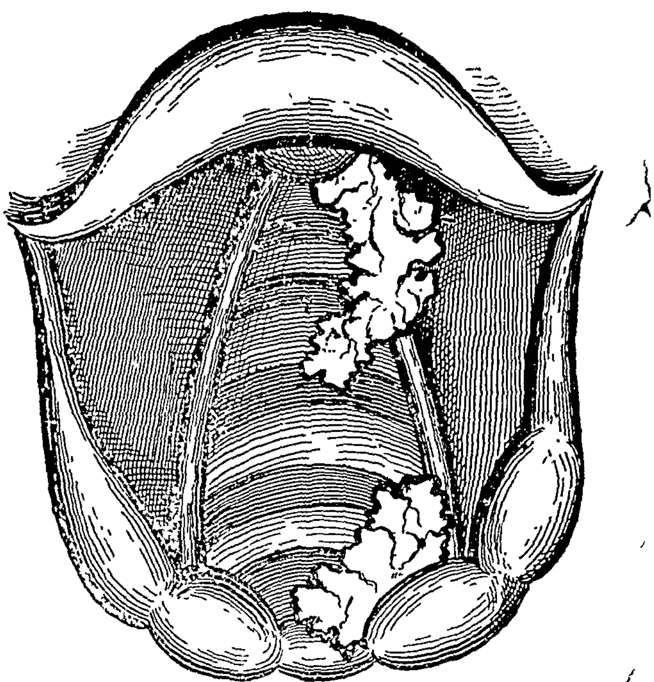

Fig. 1.—In June, 1886.

My reply to this, was to send him the growth that had been removed from the epiglottis and preserved in a solution of chloral.

He wrote me again January, 1887, stating that the gross appearance of the little tumor sent him certainly resembled papilloma, but that his eyes then debarred him from the use of the microscope. On January 11, 1887, the case again returned with oppressive breathing, and the larynx refilled with a cauliflower excrescence. Removal per *vias naturales* was followed by relief. This time I could not remove all the growth, and on January 23, at 12:30 A.M., I was summoned to go to the boy a mile in the country. On my arrival, I found the resident physician of the Confederate Soldier's Home, Dr. Franklin, endeavoring to resuscitate an apparently dead body. There was no perceptible respiration, the pulse could not be detected at the wrist and the only evidence of life was a feeble heart beat.

I opened the trachea by the inferior method of tracheotomy as rapidly as possible. When the air was admitted there was no inspiration and no cough from irritation of the trachea. Artificial respiration was commenced and kept up continuously about three hours. Any cessation of it was followed by disappearance of the apparently restored respiratory action. The trachea was opened at one o'clock, and consciousness returned about 8 o'clock A.M. The boy recovered rapidly from the effects of the asphyxia and the operation, and two weeks later came to my office. I removed the growths again, and repeated the operation several times in the next six weeks. Each operation seemed to be followed by rapid repullation of the growths, and in March they projected above the level of the cartilages of the larynx preventing the epiglottis from closing the latter. They also extended sub-glottically down to and out of the tracheal opening when the tube was removed to be cleansed. I several times passed a wire loop through the external opening in a small rubber tubing up and out through the mouth, cutting off pieces of the growth from the sub-glottic region. I have also seized them, and drawn them out through the opening in the neck. These operations were repeated from time to time until I filled a half ounce bottle with the tissue. Microscopic examination months after showed the character of the tumors to be unchanged.

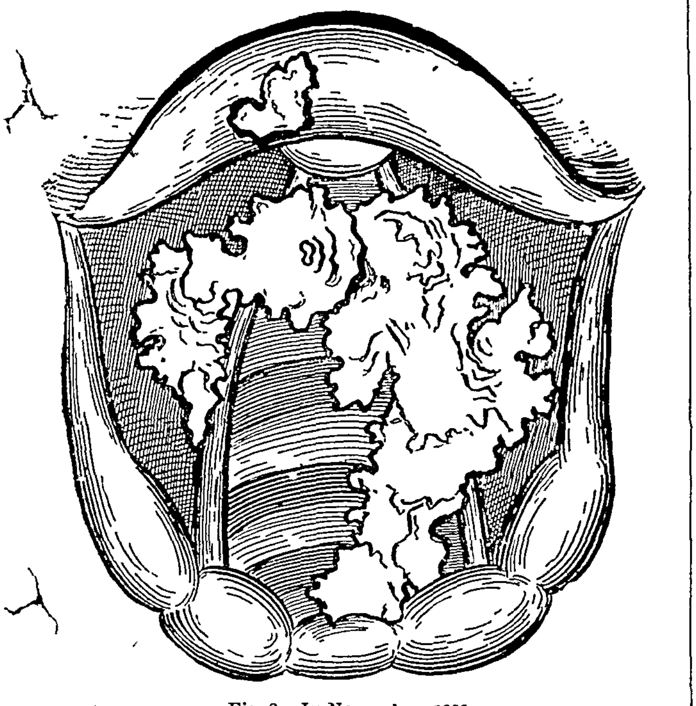

Fig. 2.—In November, 1886.

At last I became disgusted with my results. I recognized that the more I meddled with the case the more abundant became the pathological formations. Several times I was about to adopt Dr. Leffert's suggestion to perform thyrotomy, but I was averse to doing this, as the voice invariably suffers, and I was not satisfied it would prevent a recurrence.

During the summer of 1889 I was absent a great deal. The boy came to my office and missed me several times, so that two or three months passed without my seeing him. When I did so, I noticed the mass had diminished in size. So I concluded to let him alone as far as instrumental interference was concerned. He came to see me now and then. I did nothing but look at his larynx and use a simple astringent spray. Under this "do nothing treatment" he generally improved, the mass constantly diminishing until the larynx began to assume something of a normal aspect.

The growth on the under side of the epiglottis also diminished *pari passu* with the laryngeal neoplasms. In April, 1892, I exhibited the case to the Richmond Academy of Medicine and Surgery, several members of which who give some attention to laryngology examined him. His condition then, as now, was an almost perfectly normal larynx, with white pearly cords, a small projection on the epiglottis at the seat of the former papilloma, and a larger remnant of the growths on the anterior wall of the trachea just below the commissure. He still wears the tube on account of the latter abnormality. I am afraid to remove it until this disappears. But instead of a full tube, he wears only a piece of a hard rubber tracheal canula, cut off just long enough to keep the opening in the neck patent. At night he wears the inner tube—in the daytime he removes this and keeps the outer tube closed with a cork; and when thus corked up he can breathe well and speak distinctly, the voice being strong and natural. To hear him speak one would not know he had a tube in the neck.

This case is especially interesting for several reasons:

1. It is, as far as I can discover, the first case on record of papilloma of the epiglottis, for although Uchermann reported a similar case to the Christiania Medical Society in 1889,[1] the date of my correspondence with Dr. Lefferts antedates this report fully two years. In his case the growth originated from the epiglottis and vocal cords in a child 7 years of age, who had been aphonic four years. He extirpated it entirely in six sittings, and had a perfect result with no recurrence.

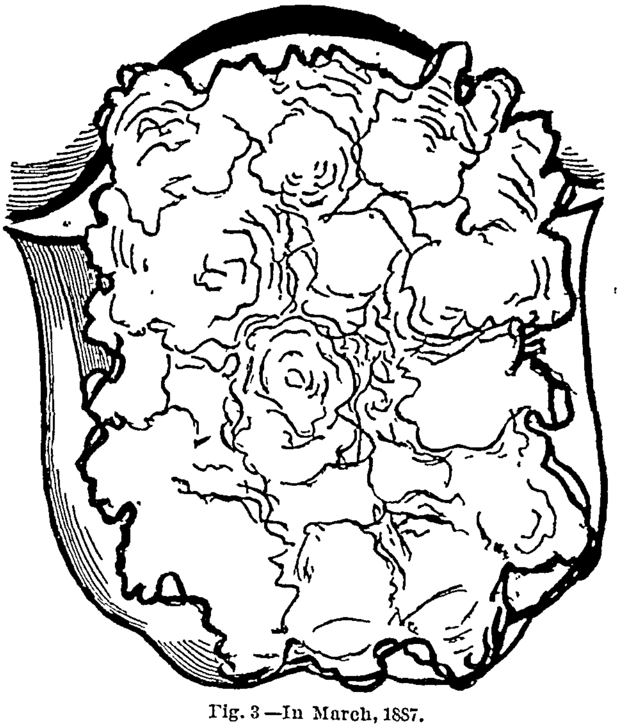

Fig. 3—In March, 1887.

Eliasberg in 1889 also reported one of secondary papilloma of the epiglottis in his case of recurring papillomata of the larynx in the case reported below. Dr. Louis A. Bull, of Buffalo, N. Y. (*Jour. of Ophthal., Otol. and Laryng.*, July, 1889), records a case of what he calls papilloma of the epiglottis and base of the tongue, but it appears to to have been an overlapping of the lingual tonsil.

2. It is the sixth case in literature of spontaneous cure of recurring multiple papillomata of the larynx after tracheotomy, the other five being two cases by Prof. Oertel, quoted by Hoppmann (*Volkmann's Sammlung. Klin. Vorträge*, No. 315); one by G. Hun-

---

[1] See report of the Christiania Med. Soc., Medicinsk Leistabs Forhandlinger, 1889.

ter Mackenzie (*Lancet*, April 6, 1889); one by Eliasberg (*Meditzinskoia Obozrenie*, 1889, No. 1, p. 46); and one by Garel (*Annales des Maladies de l'oreille et du larynx*, June, 1891). In Mackenzie's case the boy was 5 years old, and wore the tube one year after the operation, which was done in 1883. Eliasberg's case was a boy 10 years of age. Thyrotomy was performed in 1887, a mass of polypoid growths removed and cauterized with Paquelin's cautery. In February, 1888, there was a recurrence. In April following thyrotomy was again performed. In June there was a second recurrence, occupying vocal cords and epiglottis. In June, 1888, alarming asphyxia necessitated tracheotomy, and a month later the neoplasm filled the larynx. Two months later this began to improve, and in December nearly all the growths had disappeared.

The canula was worn until March, 1890, when it was removed, as it caused irritation with bleeding granulations about the wound, and cough. The voice became very harsh because of the thyrotomies previously performed.

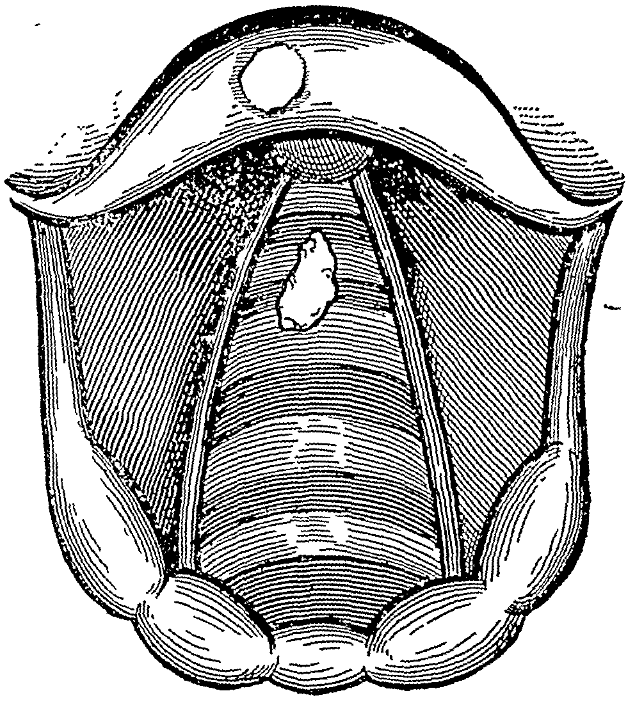

Fig. 4.—Status Præsens.

Garel's case was a girl of 4 years who was tracheotomized after an attack of suffocation June 11, 1890. The presence of papilloma in the larynx was demonstrated by laryngoscopic inspection. The tube was removed July 30, forty-nine days after the operation, all signs of the growth having disappeared.

Garel also speaks of another case in which he did tracheotomy on a boy 11 years old for presumed growth in the larynx, but as he was unable to see into the windpipe, the diagnosis was doubtful. In all of these cases there was the same result, a spontaneous disappearance of the growths, following tracheotomy, although in each one the tube was worn during a different period. Garel's case was the shortest (forty-nine days), and mine was the longest (five years). Eliasberg's case resembled mine more closely than any of the others.

There was the same tendency to repullation of the papillomata after each attempt at their removal, the same enormous development of the growths almost immediately following the tracheotomy, and the same gradual shrinkage of them when all operative interference ceased.

3. It shows that the tracheal canula can be worn indefinitely without secondary paresis of the vocal cord, or impairment of the voice, and that in such cases it is best not to be in a hurry to remove it, because of the probable development of tracheal polyps after the operation. In this case they developed even after the larynx was clear of any abnormality, and he still retains the tube, because there is a small remnant on the anterior wall of the trachea.

These growths are of two kinds: 1. Vegetations existing whilst wearing the tube and retarding its removal; and 2, growths appearing after removal of the tube and healing of the wound; but the latter danger is only to be feared when we are in too great a hurry to get rid of the tube. Sometimes if their pedicle is weak they may be coughed out, otherwise a secondary tracheotomy may be necessitated by the consequent suffocative spasms, and death may result from one of these attacks before the operation can be performed. That this is no imaginary danger is shown by the fact that over twenty cases have been recorded, by Gigon (*Union Med.*, 1862), Wanscher (*These de Copenhagan*, 1877), Archambault (*France Med.*, 1879), Voight (*Jahrb. fur Kinderheilk.*, 1882), Kock (*Arch. fur Chirurg.*, *t. xv*), Waldsberg and Reedel (*Deutsh. Zeitsch fur Chirurg.*, *t. xv*), Kohl (*Tese de Zurich*, 1887), Hume (*Cleveland Med. Gaz.*, 1886), Revilloid (*Rev. Med. de la Suisse Romande*, March, 1891), and others.

The risk of a too early removal of the tube is also shown by a case recorded in one of the last numbers of The Journal of the American Medical Association, April 30, 1892, by Dr. F. G. Raynor. A girl of twelve [illegible] months was tracheotomized during an [illegible] by Dr. Sherwell, Nov. 9, 1889. On the 20th, thyrotomy was performed and the larynx thoroughly cleaned out. Two days after the tube was removed. June 5, 1890, seven months after, she died in a suffocative attack before assistance could be obtained. Had the tube been worn long enough to be sure there would be no recurrence, the result might have been more favorable.

4. The result in my case helps to show the advantage of tracheotomy over thyrotomy in recurring papillomata of the larynx. Some writers claim the latter operation to be free from danger to life and even to voice if properly done, but I doubt if statistics bear out this assertion.

A. Malthe (*Norsk Magazin for Lagevidens-Kaben*, 1886, p. 490), reports a case in a four year old boy of multiple papilloma of the larynx tracheotomized June, 1883. On August 15, thyrotomy was performed to remove the growths, and on August 20 the child died. Salzer (*Langenbech's Archives, Band 39, Heft. 2*), in his report of the laryngeal operations in Billroth's clinic from 1881 to 1889, records ten cases of thyrotomy with three deaths. These references prove it is not free from danger to life, and it is an untenable claim made by Shalita of Kiev (*Uratch*, 1889, No. 17, p. 389), that it will not affect the voice if properly done. I doubt if any of us has ever performed it without detriment to the voice.

Bornemann (*Deutsch Med. Wochen.*, 1891, No. 15), in reporting four cases of multiple papillomata in children from B. Fraenkel's clinic in Berlin, in three of which thyrotomy was done, and in one (6 years old) an endolaryngeal operation was successfully performed, claims that the latter method is preferable to the former, because of the danger to voice and life from thyrotomy. Tracheotomy has the great advantage over thyrotomy that it gives perfect rest to the larynx, by temporarily suspending its respiratory functions, thus in all probability removing some irritating factor in the redevelopment of the growths, whilst guaranteeing unimpeded respiration without risk of suffocation.

Thost ("*Ueber papillom in der oberen Luftwegen*" *Deut. Med. Woch.*, May, 1890), in a capital article on this subject, states that papillomata of the larynx in children will always disappear spontaneously if let alone, that it is benign neoplasm, and without danger. If this is correct, why should thyrotomy with its attendant risks to life and voice be performed? Is is it not better to let such cases alone, merely keeping them under observation to guard against suffocation from any sudden or unusual excessive development. It is only in these exceptional cases that tracheotomy is called for, and it will be all the surgical interference required. Malignant growths in children are rare and these proliferations of the mucosa, as papilloma are claimed to be in contradistinction to organized tumors, are comparatively free from danger. Their causation is uncertain, but any direct irritation of the laryngeal mucosa can produce them. Probably they often result from naso-pharyngeal secretions dropping into the larynx at the arytenoid space, and which not being coughed away, act as a local irritant.

Lennox Browne ("*A case illustrating the possibility of hypertrophy of the pharyngeal tonsils being an etiological factor of papillomata in children,*" *Brit. Laryng. and Rhinolog. Ass'n.*, Nov. 1890), reports a case upon which he bases an argument to show that adenoids of the naso-pharynx are a factor in their production. This is probably true, as adenoids are accompanied by considerable secretion which may drop into the larynx, and keep up a prolonged irritation of the mucosa.

CATARRH OF CHILDBEN AND THE IMPORTANCE OF EARLY TREATMENT.

Read in the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY LOUIS C. CLINE, M.D.,
OF INDIANAPOLIS, IND.
PROFESSOR OF LARYNGOLOGY AND RHINOLOGY IN THE MEDICAL COLLEGE OF INDIANA

In this paper I wish to consider briefly, nasal catarrh as met with in children, and characterized by an inflammation and purulent discharge from the nasal and naso-pharyngeal mucous membrane.

The word catarrh in the sense that it is ordinarily used, is a kind of cloak to cover up our lack of knowledge of the true inwardness of these cases.

The literature on this subject is rather confusing and unsatisfactory.

MacKenzie recognizes two forms, acute and chronic; under the acute form, he classes the gonorrhœal and leucorrhœal infection that may occur in the new born.

Frankle describes but one form, the acute. Cohen is inclined to attribute all cases of purulent discharge to remote specific infection. Lennox Browne, Sajous, Seiler, and Robinson, make no special mention of purulent discharge in children, but class it along with other cases and hypertrophied glandular structures.

Bosworth in his recent work, devotes a small chapter to purulent catarrh of children, in which he takes the ground that "it is purely local in character, and depends on no constitutional taint, and consists essentially in an increased secretion of mucus in the earlier stages, together with a rapid desquamation of the epithelial cells, which runs its course as a purulent disease in from five to ten years, developing finally into atrophic rhinitis."

In children up to the age of 12 to 15, epithelial structures are especially liable to take on diseased action; we see this manifested in the frequent hypertrophic condition of the glandular structure of the naso-pharynx; whereas in adults, the inflammation of mucous membrane results in hypertrophy of the connective tissues.

During childhood, the lymphatic system undergoes its greatest development: hence it is, that the lymph glands are more prone to alterations of nutrition than in adults.

In children there is great activity in the development of epithelial cells, and when stimulated from any cause, may lead to one of two distinct results. Ist, they may pile themselves upon each other and so adhere as to form a true epithelial hypertrophy, together with an increase of lymph tissue and lymph corpuscles, as in the case of adenoid growths and many enlarged tonsils; this form is likely to follow scarlet fever, measles or diphtheria. 2nd, the epithelial cells may fail to adhere and result in a rapid desquamation, with an increased flow of mucus, forming an abundant muco-purulent discharge.

Both these processes may go on in the same case, or desquamation from the turbinates may follow the adenoid growths in the vault.

My observation leads me to believe that children of a strumous or scrofulous diathesis are more prone to take on the second form, or exfoliation of the epithelial structures.

An acute cold of a child differs from that of an adult, in that the inflammation involves the epithelial coat and naso-pharyngeal glands, thus producing nasal-stenosis; while in the adult, the inflammation involves the mucous membrane proper, extending into the deeper structures.

These inflammatory changes commence as a rule, in children between the ages of three and five years, and if not cared for, will culminate in one of two results, or may be, a combination of both: viz., the desquamative or suppurative form, or the coalescing or adenoid form.

If the case is confined strictly to the desquamative variety, it will gradually extend into the mucous follicles and rob them of their epithelial lining and destroy their secretive power, and in this way lead to formation of crusts, and finally terminate in atrophic rhinitis, about the 14th or 15th year.

The characteristic symptom of this disease, is a muco-purulent discharge from both nostrils, usually of a cream or straw color, and can be diagnosed from the other varieties by there being no special obstruction to the nasal passage, except the accumulation and drying of the secretions. In case of a foreign body the discharge is always confined to one side. In syphilis and in cases of necrosis, the discharge is very offensive. When the discharge is due to adenoid growths, the first thing noticeable is the marked altered condition of the voice, which is not changed on removing the secretions. In these cases, large quantities of tenacious mucus are found in the naso-pharynx. In those cases in which the adenoid growths are large enough to materially obstruct the naso-pharynx, the discharge makes its way through the nose: this, with the characteristic facial expression, muffled voice, together with careful inspection with the rhinoscopic mirror, will be sufficient to make a correct diagnosis.

In a list of twenty-five carefully noted cases that have applied to me for treatment for nasal catarrh during the last year, five were suffering from a purulent discharge due to exfoliation of the epithelial coat. Three were due to foreign bodies, one to a fibrous tumor, sixteen to adenoids in the vault and enlarged tonsils,etc. Hearing was impaired in twenty-one of these cases directly in proportion to the degree of stenosis, and the length of time the difficulty had existed. Suppuration and rupture of the membrana tympani had occurred in six of these cases; three of these followed the grippe. Seven had developed after having measles, five after scarlet fever, four followed diphtheria, and five gave a history of repeated colds.

Thus we see, out of the above twenty-five cases, only five were found to be strictly catarrhal. The other twenty were complicated with and continued by adenoid growths, enlarged tonsils, foreign bodies, etc. These children were all well cared for, and properly clothed.

A peculiar feature of these cases is that the sixteen cases that had enlarged tonsils and adenoids in the vault, all followed either diphtheria, scarlet fever or measles; while the five purely catarrhal cases gave no history of these diseases but all gave evidence of a strumous or scrofulous diathesis with frequent colds.

I have purposely avoided confining my remarks in this paper to any special variety of cases, but have included all cases that have applied for catarrhal treatment, and from a careful study of these cases, I have thus far reached the following conclusions:

That hypertrophied turbinates, adenoids in the vault, follicular pharyngitis, and enlarged tonsils, are very liable to follow diphtheria, measles and scarlet fever, while the exfoliation of the epithelial coat or the purely catarrhal variety, is more likely to follow repeated colds in the strumous or scrofulous children.

If these two points were more carefully studied by the general practitioners, and less advice, such as consoling the parents and themselves that the child will soon outgrow the difficulty, there would be fewer death certificates to sign, and fewer seeking ear trumpets when older.

When we consider that the treatment involves no risk to the patient and that these growths are the seat of repeated attacks of acute inflammation which is liable to extend to other organs, as the ear, is sufficient evidence that we should not wait for nature to effect a cure through absorption and atrophy.

While there is a tendency to glandular atrophy, at puberty, they seldom entirely disappear, but remain as a constant source of naso-pharyngeal catarrh. The fact that these patients get better after they arrive at the age of puberty, is largely due to the arrest of glandular growth, and the great development which takes place at this age, causing the enlargements to occupy less space in the air passages.

As a rule, we are warranted in giving a favorable prognosis in these case, even when extensive ear complications have set in. In fact, many cases do not apply for treatment until the ears become involved.

The treatment of these cases embraces general and local, to which I will refer briefly. Constitutional treatment with tonics and cod liver oil, is indicated in cases where the general health is impaired by imperfect oxygenation of the blood and disturbed sleep from interference with the normal respiratory functions.

The local treatment in the purulent variety consists in some mild alkaline solution to keep the parts clean of the muco-purulent discharge, followed by some slight astringent. The cleansing lotions are best applied with a small hand atomizer. Douches are objectionable as a rule.

The cases should be watched and the treatment changed as the case demand.

In those cases of glandular hypertrophy, unless seen in the beginning, nothing short of surgical interference and a thorough extirpation of the offending structure will effect a cure.

This is best done by cutting instruments or snare. Owing to the prejudice of many to surgical operations, we are compelled to resort to chemical agents and the cautery for the destruction of these growths. I prefer using the galvano-cautery when not permitted to use cutting instruments, but complete extirpation by surgical operation is always to be preferred to any other method.

The general law of surgery applies to all of these cases, when there is an offending obstruction, the sooner it is removed, the easier the cure and the less liability to complications.

Discussion.

Dr. Casselberry, Chicago:—The term "catarrh" is objectionable as defining too little, as referring to its symptom merely of discharge or disturbance in the upper respiratory tracts; we should seek to become more explicit in our nosology and this the author of the paper has done, by well describing the various forms of rhinitis, etc., and their causes, still another such cause I would suggest to be not infrequently a nasal rhinolith or calculus which may form during an acute attack and then perpetuate the disease.

Too much stress cannot be laid upon the importance of treatment in children, because irreparable damage to the ear is still deplorably common simply from neglect, or inefficient treatment. I believe all such cases to be capable of cure if promptly and effectively handled.

With young babies, who suffer frequently from purulent rhinitis, the result of infection by the vaginal discharges during birth or otherwise, I advise thorough cleansing with an antiseptic and alkaline lotion, such as *Dobell's solution*, injected into the nostrils by means of a syringe; a medicine dropper may be made to serve as a substitute for a syringe in the hands of the nurse or mother. Sprays, I find to be too slow in use and to frighten the child. Adenoid vegetations should be removed, but the naso-pharynx seems to be an active absorbing surface and the galvano-cautery among a mass of adenoids, is apt to produce such a large necrotic eschar that I have had several cases of septic infection follow its use. Hence, I prefer the cutting and scraping operations. Many mild cases can be done by the finger nail; others by cutting forceps or curettes, rapidly or by repeated sittings with or without a general anæsthetic. Many children, by proper management, can be induced to tolerate the operative treatments; others cannot and then ether anæsthesia may be employed.

To be more explicit regarding the cases for operation under ether: 1. When the faucial tonsils should at the same time be removed. 2. For the removal of large hard dense fibrous adenoids—those not readily scraped away by the finger or curette. 3. Those in which it may be expedient to use a general anæsthetic on account of the unwillingness of parents to see their children suffering and bleeding while conscious. The risk of anæsthesia is less than the damage liable to ensue if the "avenoids" are not removed at all.

When ether anæsthesia is complete, the child is held in a sitting position by an assistant, the mouth held open by a gag, the faucial tonsils first removed by a cold wire snare which is armed by a steel wire, heavier than usual, so that it will maintain the contour of its loop. This is placed against its tonsil and the tonsil then drawn outward and steadied by a volsellum. This snaring can be rapidly done, without hæmorrhage. Guided by the finger its adenoids are then removed by cutting forceps. At times of active hæmorrhage, the child can be inclined forward for a couple of minutes so that the blood will flow out of the nose. The whole operation need not occupy over half an hour and there is little soreness following it. The results are highly satisfactory.

Dr. John North, Toledo, Ohio:—I do not like the term catarrh. Catarrh is simply a symptom of some other trouble, either constitutional or local. In these cases of purulent catarrh we find some cause that acts upon the cells, we find in the second layer of mucous membrane, if these cells become ripe in a healthy membrane they form the epithelial cells, if from some cause they are modified they are thrown off from the membrane as mucous corpuscles, if they are abated in the development they become pus corpuscles.

Where there is enlargment of the so-called lymphatic tissue of the upper respiratory tract, I get good results from the local application of 60 grains of sulphate of copper to the ounce of water. I also give some form of the iodides. Iodide of iron if necessary or iodide of ammonia.

Dr. H. W. Loeb, St. Louis, thoroughly agreed with the writer in his designation of the causes of nasal catarrh in children and also in his statement as to the importance of its early treatment. In the removal of adenoid vegetations in the vault of the pharynx, he has been accustomed to perform it very frequently without the use of an anæsthetic. A small portion is removed every second day and thus far the result has been satisfactory. No pain is necessarily occasioned and patients readily submit to such manipulation without resistance.

Instead of using a cold wire snare, the Doctor has used a galvano-cautery snare, which he has devised and which permits the removal of the tonsil in a very short time, no hæmorrhage resulting.

Dr. Waxham said: The papers to which we have listened have been so excellent that I hesitate about taking part in the discussion, but there is one thought to which I would give expression. I must confess that I am skeptical as to the occurrence of a simple croupous rhinitis independent of diphtheria. A case coming under my observation led to this skepticism. A patient, nine years old, was brought to my office with a well marked membrane in one nasal cavity which ran the usual course and without extending to the other nasal cavity or to the pharynx. As there were no constitutional symptoms, no fever and no rise of temperature, the case was not isolated as it was considered not contagious. In a few days a young infant in the family developed genuine diphtheria, involving both nasal cavities, the pharynx and the larynx, proving fatal. This case, I confess, has made me extremely skeptical as to the non-identity of croupous and diphtheritic rhinitis and has convinced me of the necessity of isolating all cases of membranous rhinitis.

Dr. DeVilbiss of Toledo:—I object to the effort that is being made to drop, or do away, with the word catarrh, for it is a word that is familiar to everybody, and it is the name catarrh more than any other that influences the laity to seek advice for their maladies. It is the business of the specialist to look into the cause and not stop to quarrel with the name. Therefore I am pleased with the term as used in the paper, and am opposed to dropping the word catarrh until it is demonstrated that there is a word that will more fully meet the indications.

PHENACETIN is said by Dr. Green to diminish the frequency of calls to urination in elderly people, especially at night, and that ten grains at bedtime will often secure rest for those who habitually rise once or more during the night.—*Universal Medical Magazine.*

HYPERTROPHY OF THE ANTERIOR TIP OF THE MIDDLE TURBINATE BODY OF THE NOSE.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY G. V. WOOLEN, M.D.,
OF INDIANAPOLIS, IND.

There is a class of symptoms connected with many cases of catarrhal disease of the nose which is ordinarily taken to indicate the disease in its totality, but not regarded as having any special signification. I refer to frontal and basilar headache, deep orbital pain often bilateral, and not unfrequently unilateral, when it is termed hemicrania; mental hebitude, sometimes associated with defective memory, and again bordering upon melancholia, migraine, epilepsy, etc.

Now we do not have these symptoms in childhood, where we find the disease uncomplicated, either as suggesting conditions which would create the disease, or with those resulting from it as usually witnessed. Therefore we must look farther for their correct signification.

They have been regarded as gastric in origin, and as gastric catarrh so commonly accompanies the nasal and throat trouble, it is easily misleading. But closer analysis will reveal that many subjects of the gastric complication do not have the symptoms, and *vice versa.*

This analysis will also reveal that all of these conditions expressed by this category of symptoms, center in those of deep orbital and supraorbital pain or neuralgia with frontal and basilar headache. Now what can the ordinary catarrhal process have to do with this condition of affairs?

It is well known that not all cases of catarrhal disease have these manifestations. And in fact, many attended with the most direful results, both atrophic and hypertrophic, leading to grave pulmonic and other lesions, are wholly without these symptoms. And yet, in the whole range of disease this combination of symptoms is not so marked or persistent as is found in many cases of nasal catarrh.

Why neuralgias of the first division of the fifth nerve exist unilaterally (hemicrania), or bilaterally from the supposed gastric and other causes, and not of the other divisions, is not heretofore explained.

In a paper entitled "Nasal Differentiation," presented to the Mississippi Valley Medical Society in September, 1889, and subsequently published in THE JOURNAL of this Association, I called attention to a full and complete appreciation of the anatomy and physiology of the parts as essential to a correct interpretation of the pathological conditions of the nose.

The text-books on anatomy describe the nose as the organ of the special sense of smell, and would lead us to believe that it was primarily for that purpose; whereas one may have good health and not be capable of smelling at all. But one cannot be well and not use the nose for respiration and as a conduit for secretions from it and the accessory cavities. That which spoils the nose for this purpose is that which leads to obstruction and pressure irritation with defective drainage. In the great majority of cases this is hypertrophic disease.

In the paper referred to, I attempted very briefly to locate the pathology of the symptoms heretofore enumerated to the ethmoidal region, and more especially to hypertrophy of the anterior tip of the middle turbinate, or lateral process of this bone.

Much has been written about hypertrophic disease of the nose in relation to the catarrhal process, but the inferior turbinates have received the greater attention, manifestly because their enlargement interferes more with the respiratory act and general drainage of the nose. But one of the commonest results of this hypertrophic process is enlargement of the anterior tip of the middle turbinate. This may be unilateral or bilateral, and associated with or without corresponding disease of one or both of the inferior turbinates. It may occur also without further hypertrophy of the middle turbinate—largely so according to my observation, and appears as a globular or oval bright-red, glistening mass, filling the naris in the upper region according as the hypertrophy is uni- or bilateral. These may at times be pale and shrunken or at others very red, irritable, completely blocking the naris. Indeed, this irritable congested condition may be found confined to one side only, and when so, the pain and neuralgias are located on that side, while the other may be wholly quiescent.

When the hypertrophies are bilateral and of equal size the septum remains central, otherwise it is deviated to the side opposite the mass, and is frequently found pressing against the outer side of the naris, causing as much pressure and irritation in it, as does the hypertrophy on the opposite side.

The question as to why a hypertrophy and a corresponding deviation opposite, whether the deviation is due to presssure from the hypertrophy, or that the hypertrophy is due to nature's effort to fill the cavity or vacuum caused by the deviation, seems to me unsettled. Probably the former. It is scarcely the result of traumatism and consequent breaking down of the septum in these parts, as it is too well protected by its outer bony coverings.

These hypertrophies being situated so far anteriorly, do not interfere with smelling unless the whole turbinate is involved, and then probably only in the later stages, when the atrophic process or polypoid degeneration obtains. To fully appreciate the disturbances resulting from this phase of disease one needs to review the outlines of the anatomy of this region.

The naris in its perpendicular axis is an irregular oval cone, with apex between the orbit and perpendicular plate of the ethmoid. The apex of this cone is broken into an uneven surface by the opening of the ethmoidal cells through which the frontal sinus discharges. In health the lateral mass of the ethmoid, which forms the outer side of this cone, and by its projection into the naris forms the middle turbinate body, diminishes in its anterior termination to a flattened projection slightly overhanging the opening of the ethmoidal cells, called the infundibulum. This projection is scarcely or not at all visible with our best means of nasal illumination and inspection.

These immediate parts are devoid of anything of further anatomical or physiological interest, except the nerve of sensation of the anterior region of the nasal cavity, the nasal, a branch of the ophthalmic or first division of the fifth, which enter the naris at its apex, from the cranial cavity, having given off in the orbit its own branches, the ganglionic, ciliary and infratrochlear. It divides into two branches which descend on the septum and outer wall of the naris. This nerve in its relation to its own branches, and as a branch of the first division of the fifth, if disturbed, gives the solution doubtless to much that we already have hinted at, *i. e.*, orbital and supra orbital neuralgias, frontal and basilar headaches following the fifth nerve, hemicrania, when only one is involved, etc. In other words, it is only a question of pressure irritation of this nerve. The blood and nerve supply to these parts being so intimately associated, it could not be otherwise than that they would be similarly affected, *i. e.*, when the nares were irritated and congested, a similar condition would prevail in all contiguous parts. Thus it is that many eye cases are now relieved by the nasal treatment.

When this special hypertrophy obtains and causes irritation, it is by its development between the branches of this nerve, therefore pressing injuriously in both directions. The pressure may be greater on the opposite side, however, from the extreme deviation of the septum and consequently the hemicrania and symptoms of distress will be on that side equally if not greater, than on the side of hypertrophy.

As a local point of reflex irritation, one would expect it to act favorably in the production of such troubles as epilepsy, and in a number of cases in which the fixed point of irritation seemed in this region, I have found this pathological condition to prevail, and upon its removal, immediate amelioration invariably occurred and apparent recovery in at least fifty per cent. of cases.

These hypertrophies, however, may exist without causing trouble when there is an abundance of room in the region of the naris. As a fact, it is not always the size which determines the gravity of the symptoms. A roomy naris may tolerate a large growth with impunity, and conversely a small one may not tolerate a small growth.

It is only when we have pressure that inconvenience follows. That this pressure is greatly hurtful in many of these cases by obstructing the outlet of the ethmoidal cells I have repeatedly proven by removing the greatly enlarged and overhanging turbinate tip and witnessing the retained secretions flow out through the infundibulum into the nasal cavity. This is also frequently seen in the subsidence of "a cold in the head."

The retention of these secretions accounts additionally for the deep orbital and ethmoidal pains encountered in this class of cases.

This blocked and congested condition of these parts unavoidably affects cerebration and furnishes a satisfactory solution of the cause of the mental hebetude, melancholia, and defective memory. The shrinkage of the obstruction either by cocaine, local treatment, dry weather, change of season, or climate, gives relief, and more positively than these, the removal of the obstruction brings permanent relief, apparently a positive proof of the causative relationship. There is nothing that I do in rhinological practice with such certain expectation of success as the removal of these masses for the relief of these symptoms.

In this connection I will state that I have invariably noticed the congestion of the nose in the ordinary "cold in the head" begins at the tip of this turbinate, if seen *sufficiently early*.

This hypertrophic tip is prone, in some cases, to undergo polypoid degeneration, prior to, and even without the other portion of the turbinate, at all, and when removed will be found to have a transparent apex resting on an opaque base, which shades off into the ordinary hypertrophic tissue, that may constitute the major portion of the mass, and where the whole turbinate is involved in the polypoid degeneration it also wholly undergoes this process.

Dr. Edward Woakes, of London (Nasal Polypi, etc., London, 1887), very ingeniously explains the troubles traceable to this region as arising from ethmoiditis, and claims there is a necrosing process to be found in the greater number of cases in the middle turbinate. However this may be in the English subject, as exhibited in his clinics, I have not subsequently found it to be true in the American, and many of the troubles which he claims arise from disease of the middle turbinate, I think are clearly referable to other regions of the nasal cavity. Furthermore, he claims it to be caused by inflammation of the ethmoid, which is disproved by removal of the hypertrophic tip and consequently pressure irritation and defective drainage, and thereby relief of the various symptoms.

The method of dealing with this enlargement is wholly by the cold snare. If it be as we have shown, an hypertrophy, we can hope to reduce it by no method of medication, and the treatment of these various symptoms has proven in the past to be at most, but palliative.

The part being so intimately associated with the anatomy of the base of the skull, cauterization is not to be thought of, and in fact fatal meningitis has been reported to have followed such practice.

The hypertrophy will usually be found to involve all of the tissues of the tip, so that periostitis and cranial troubles would be easily awakened by cauterization.

If removed properly a tip of the bone is usually included in the mass. To do this completely the loop of the snare should be carried under tip, allowing the canula of the snare to pass anteriorly to the mass and gently pressed in front and above till slight resistance is felt, when it should be held steadily till the loop is brought home. This I always do as rapidly as possible to abbreviate the pain and have never had a troublesome hæmorrhage. If the mass is large cocaine can be used, but if not, it is apt to shrink it so as to let the loop slip over it.

It should be remembered that in a state of health no one is able to place the snare loop over this tip because of its retracted and flattened shape. Usually the upper region of the naris is so filled with the tip that any preparatory antiseptic measures cannot be used, but when the small hæmorrhage which follows the removal has ceased, the parts should be thoroughly cleansed and dressed antiseptically, and healing will occur surprisingly soon, even when the tip of the bone is removed. It is my custom to keep my patient fully under the influence of the bromides prior and subsequent to the operation for several days.

Following the suggestion that colds seem to manifest themselves primarily in this region, it has become my custom, also, as suggested originally by my assistant Dr. Hibben, to remove this mass first when it becomes necessary with other surgical proceedings, so as to avoid exciting sympathetic troubles in this region, and with most satisfactory results.

Discussion.

Dr. Casselberry, Chicago:—I recognize several forms of enlargement of the anterior end of the middle turbinate body.

1. Simple hypertrophy confined to the soft parts.
2. Myxomatous hypertrophy, or degeneration either alone or associated with hypertrophy elsewhere in the nose.
3. Enlargement of the bony-base of the body together with the overlying soft tissues.
4. Necrosing ethmoiditis of Woakes with enlargement and duplication of the body, it appearing like two turbinates side by side with a slit between.
5. Cystic formation of the bone.

The treatment is necessarily surgical. For this purpose I prefer first the snare, but in some instances it is difficult to pass this; then a turbinate scissors, which I devised and described for this purpose, in connection with the radical treatment of myxomata which spring from beneath this turbinate body. Also at times a fine saw of the Roe pattern can be used.

I am not altogether in accord with the writer regarding the exclusion of the electro-cautery in operating on this body. I have made this a part of the treatment of nearly all cases of hypertrophic rhinitis which usually suffer from hypertrophy of the middle turbinate, as well as the inferior body. The only well authenticated case of meningitis following cauterization in the nose, reported by Wagner, of Germany, followed cauterization of the inferior body. Cauterization anywhere in the nose should be done with strict antiseptic precautions, and perhaps greater care, if possible, be used concerning the middle body, but if care be observed to cauterize only at points where drainage will be reasonably good—that is, along the inferior surface of the body, it can be safely done. Too much surface should not be burned as considerable cicatricial contraction subsequently ensues and dry incrustation is certainly a possible result.

Dr. Seiss called attention to the jamming of the *middle* turbinate in cases of sclerosis of the lower scrolls—the respiratory lumen being too wide while the middle body was subjected to pressure. The enlargements are prone to undergo myxomatous degeneration, becoming polypoid in character.

Reported case of lady aged 24, who suffered from great asthenopia, headache, and mental fatigue. On examination a small myxomatous mass was found on the septum pressing against the middle scroll. A number of light galvano-cautery incisions were made into the mass, and sedative sprays applied over an interval of some weeks. Complete relief resulted, which at the end of a year continued permanent.

Dr. Randall, Philadelphia, wished to confirm the statements of Dr. Seiss as to the value of cauterization or other treatment of the hypertrophic middle turbinal in some cases of asthenopia. Nasal examination constituted a part of his ocular investigation in such cases and he could report many cases of good result, not so brilliant, perhaps, because he had treated them himself instead of referring them to a more skilled worker. A recent case, seen with Dr. Seiss at the Polyclinic, had shown very marked relief of mental symptoms suggestive of meningeal irritation as the result of cauterization of his middle turbinate.

Dr. Wright, Brooklyn:—Cautery of the middle turbinate bone, I have been accustomed to do with some caution, more from theoretic considerations—of the nearness of the middle turbinated bone to the base of the brain. I am accustomed to do it by means of a fine platinum point plunged into the submucous tissue. When healing occurs the turbinated body shrinks away from the septum and so relieves pressure. This method is only applicable where there is no bony hypertrophy, where the mucous membrane is alone the offending body. Although I also use the nasal snare where the hypertrophy is large and bulbous, I desire to emphasize strongly the danger of taking away too much of the middle turbinated body, as when this is done the base of the skull and the important structures it supports are exposed to the blast of air from below in blowing the nose and in strong expiratory efforts. One such case forms a part of my experience, where severe headaches lasted for several months caused in this manner. Where there is bony hypertrophy to be reduced I have, in a few cases, succeeded in doing so by morticing the under surface of the middle turbinated bone with a nasal trephine and then with strong probe or forceps forcing the inner plate of the mortice outward against the outer plate—in other words the middle portion of the bone is removed and the outer shell left on each side with the investing mucous membrane on each side.

Dr. J. Walter Park, Harrisburg, Pa:—I can fully substantiate the mental condition in cases of nasal stenosis, due to hypertrophy of the middle turbinated bodies, cited by Dr. Woolen, of Indianapolis, but differ somewhat in its treatment. Mr. S. was referred to me by the Supt. of the State Lunatic Hospital, of Harrisburg, Pa., who was suffering from the incipient stages of insanity and nasal stenosis. Physical examination showed a hypertrophied condition of both middle turbinated bodies, and undoubted suppression of the free discharge of mucous from the frontal sinus. After cauterization and the entire removal of this stenosis, there was an entire removal of the mental symptoms, and the patient at the expiration of seven months still remains perfectly well. I differ with Dr. Woolen (who stated that cauterization caused meningitis and should not be used) and will say that my experience has been entirely with the actual cautery, and have had no bad results whatever from its use.

DISEASES OF THE NASO-PHARYNGEAL PORTION OF THE RESPIRATORY TRACT, THEIR RELATION TO, AND ULTERIOR EFFECTS UPON THE GENERAL HEALTH.

Read before the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY P. C. JENSEN, Ph.C., M.D.,
OF MANISTEE, MICH.
Late of Chicago, Member of Chicago Medical Society, and American Medical Association.

Mr. President, Officers, and Members of the American Medical Association, Gentlemen:

I here submit for your kind consideration, an article entitled, "The Diseases of the Naso-pharyngeal Portion of the Respiratory Tract; their Relation to, and Ulterior Effects upon the General Health."

My reason for selecting this subject, is because of the practical relation which it sustains to many of the diseases coming under the observation of the general practitioner. But before proceeding farther, I wish to offer an apology to the Association for briefness, as the subject is too extensive to expatiate upon, at any considerable length, in the space here allotted.

Owing to the geographical distribution of nose and throat affections in this country, their prevailing frequency in our large cities, and along the borders of our great lakes, it is an experience of most frequent occurrence to observe the effects of sudden changes of temperature, upon the human organism.

Fluctuations of temperature and humidity with their concomitant barometric variations, are conjointly responsible for the induction of vaso-motor disturbance, causing in the individual, an inequality of the circulation, thereby contributing an influential factor to the production of vascular fullness, and blood stasis of the mucous membrane lining the nasal cavity, involving the inferior and middle turbinated bodies, and not infrequently extending throughout the mucous structures of the naso-pharyngeal cavity. These phenomena and the hyperæmia resulting therefrom, represent the primary deviation from the physiological condition, and constitute the first step in the pathological action that occurs in the process of taking cold. *That a wide-spread* tendency exists, exerting its peculiar influence, in predisposing individuals to take cold, is I believe the common observation and experience of the majority of physicians.

This statement I believe finds confirmation in the fact that a large proportion of the population in our temperate climates, are affected with a mild grade of chronic inflammation of the nasal mucous membrane; chronic inflammation of any anatomical structure, whether it be bone, tendon, muscle, nerve, synovial, serous or mucous membrane enduces in such structure, a hyper-sensitiveness to exciting causes of disease.

Of etiological influences, the sudden alternation of heat and cold, and the transition from a dry to a humid atmosphere, or *vice versa*, are the most influential in the production of colds, coryza, and the development of inflammation of mucous membrane, in any cavity or portion of the body to which such membrane is distributed as an anatomical part.

Of other important etiological conditions may be mentioned debilitating influences, excitement, previous and present disease, hereditary constitution, temperament, age, sex, occupation, etc. But other disturbances and cognizable agents, are circumstantial as exciting causes of disease, the most influential of which are: 1, mechanical influences; 2, chemical influence; 3, mental emotion; 4, nervous influences, and the so-called reflex neurosis; 5, defective sanitation, as imperfect ventilation; cleanliness or drainage; 6, imperfect digestion; 7, defective elimination; 8, excessive or deficient physical exercise; 9, excessive evacuations; 10, the so-called auto-genetic poisoning; 11, and last, epidemic, endemic and infectious poisons.

Owing to the prevailing frequency of chronic mild rhinitis and its existence in many individuals, to whom it is the cause of but slight inconvenience, or it may be scarcely any except when a cold is contracted by one so affected, this chronic process is developed into an acute inflammation. I am therefore disposed to believe, that chronic affections, such as rhinitis, post-nasal catarrh, or naso-pharyngitis, tonsillitis, laryngitis, tracheitis, bronchitis, etc., are the results of repeated colds, or attacks of acute inflammation, but that when a rhinitis once becomes chronic, it assumes the rôle of a predisposing cause in taking cold, by reason of the irritability and supersensitiveness which characterize inflamed structure.

Indeed for this reason an often recurring coryza is a presumptive diagnostic symptom of chronic rhinitis, and should always be supplemented by a rhinoscopic examination of the naso-pharyngeal cavity, in order to determine the differential diagnosis. The results of an exposure to cold, will differ in different individuals according to habit, occupation, degree of exposure, etc., and the course of morbid action will be largely dependent upon dyscrasiæ, susceptibilities, temperament and inherited or acquired conditions, etc. In the majority of cases, the result is an acute inflammation of the mucous membrane, which lines the nasal passages. In others, it gives rise to pharyngitis and tonsillitis.

In some instances laryngitis, tracheitis and bronchitis are developed; while in others, irritable bladder-cystitis, nephritis, oxaluria, lumbago, rheumatism, and neuralgia may occur. This diversity in results upon different people, from exposure to cold, is most readily explained when it is observed that inflammation resulting from an attack of cold locates itself by preference in the weakest part of the organism. To illustrate, an individual of highly nervous temperament, if anæmic and debilitated, when exposed to cold is liable to an attack of neuralgia. A person subject to rheumatic trouble, upon exposure, most frequently contract an attack of rheumatism. If there be a bronchial weakness, an exposure will be followed by an attack of bronchitis, or perhaps bronchial asthma.

The neurotic temperament, predisposes, and the effects of extreme debilitating influences from prolonged mental strain or from physical fatigue, invariably renders the subject peculiarly susceptible to cold in the head. Occupation, such as bakers, blacksmiths, cigar makers, firemen, engineers, furriers, millers and chemists, whose business necessitates the endurance of alternate hot and cold temperatures, or the continual exposure to dust, irritating gases or poisonous vapors, renders the individual especially susceptible to rhinitis or naso-pharyngitis.

The frequent association of such nasal diseases as chronic hypertrophic rhinitis, nasal stenosis, polypus, post-nasal adenoids, hyperplastic and hypertrophic inflammation of the nasal mucous membrane, and their relation to various neuroses as chorea, asthma, paroxysmal sneezing and hay-fever; also the disappearance of the secondary affections upon correcting the nasal abnormalities, suggests causal relation.

Intra-nasal diseases are therefore frequently the cause of a series of secondary affections, the development of which are often anatomically remote from primary cause. These secondary diseases may occur from direct irritation, and continuity of structure, or from reflex action. From the former cause may be mentioned, Eustachian catarrh, acute catarrhal otitis media, pharyngitis, tonsillitis, laryngitis, tracheitis, bronchitis, gastritis, duodenitis, enteritis, etc. While to the latter may be attributed the so-called sensory, motor, or secretory neurosis of peripheral origin as nasal or bronchitic asthma, paroxysmal sneezing and hay-fever, asthenopia, epiphora, conjunctivitis, supra-orbital, hemicranial or trigeminal neuralgia.

The symptomatology of intra nasal disease, both objective and subjective, will depend upon the form of disease present.

In polypus the subjective symptoms are generally those of obstructed nasal respiration, frontal headache, intra-nasal pressure, with a sensation of constriction across the bridge of the nose, snoring during sleep, anosmia, pharyngeal and laryngeal irritation and naso-pharyngitis.

The nasal obstruction may be bilateral or unilateral, partial or complete, or alternately unilateral, according to the anatomical attachment of the polyp, and the nature of the pedicle, whether sessile or pedunculated.

Their history usually dates from a period when the patient experiences increased susceptibility to colds in the head; the attacks repeated with increased frequency, until the catarrhal symptoms of the patient are fixed and constant. Cough, asthma, palpebral and lachrymal irritation, and neuralgia may occur as reflex symptoms more to be regarded as sensory neurosis of peripheral origin; while vertigo, loss of memory and inaptitude for mental and physical exertion, are symptoms to be referred more particularly to the anæmia resulting from interference with respiration, and other blood deficiencies and contaminations, from further secondary implications, rather than to that of reflex irritation.

A profuse rhinorrhea is a common condition, when two mucous surfaces are brought into contact with each other, the effect of which is very debilitating upon the patient. The speech is usually thick and guttural from a semi-paretic condition of the palate, which will be observed to possess the usual characteristics of nasal obstruction.

The symptoms are all more aggravated during damp weather, owing to the hygrometric properties possessed by œdematous structures.

When buccal respiration has been practiced for a considerable period of time, the alæ nasæ, may, from want of use, acquire a tendency to collapse.

The sense of smell is usually seriously implicated, although taste of flavors may be normal. Tinnitis aureum and deafness from catarrhal inflammation of the Eustachian tubes or direct mechanical occlusion of them is not uncommon, nor should it be forgotten that lachrymal abscess has resulted from pressure upon the nasal duct. (Greville MacDonald.)

The symptoms of nasal stenoses, from other causes, differ from those of polypus in this particular: that in stenosis the obstruction is permanent with change of position, which is not the case with polypus.

Obstructive nasal disease aside from its influence over speech, also affects intonation of the voice to a considerable extent. The removal of post-nasal obstruction therefore raises the pitch of the voice, and improves phonation.

The local symptoms of chronic catarrhal rhinitis are of small importance and of little diagnostic value; they are indicative of nasal disease, a rhinoscopic examination being necessary to complete the diagnosis.

The important symptoms are buccal respiration, inability to blow the nose, headache, vertigo, the typical buccal speech, and snoring during sleep, and not infrequently rhinorrhea.

The general symptoms are those of languor, lassitude, and fatigue, which often appear worse in the morning than at night. There is usually present muscular soreness, limited sometimes to groups of muscles, which are symptomatic of systemic depression from mucoid poisons and various pepto-toxines, leucomaines, albumoses and other system poisons.

There is usually a furred tongue, a bad taste in the mouth, or a dry sticky sensation in the throat.

The bowels are usually constipated, and in the majority of cases a strong tendency to melancholia exists; while the closed mouth, fœtid breath, inspissated mucus hawked from the throat more often than blown from the nose, and the speech approximating the cleft palate patient, are associated with the reverse condition, viz.: abnormal patency of the nasal fossæ, and it is in such cases that atrophic changes usually occur. The character of the discharge aside from its degree of inspissation, whether mucous or muco-purulent, is often of little importance if bilateral; but when purulent, or unilateral, it may be of considerable importance, especially as suggesting grave structural disease of the ethmoidal cells, or empyæma of the maxillary frontal or sphenoidal sinuses.

The distinction between mucus and pus can easily be made both chemically and microscopically. Pain is not always important, cough is occasionally a prominent symptom in obstructive nasal disease, and apart from concomitant laryngitis, nasal cough is usually dry and barking in character. The olfactory function is of but slight value in diagnosis, as very insignificant and imperceptible causes interfere with its performance. Indeed the objective appearances are the only symptoms of much diagnostic importance.

The differential diagnosis between true rhinitic hypertrophy of the turbinated and vascular tumefaction of the erectile tissue is easily accomplished, by the application of a solution of cocaine, which causes vascular collapse of the erectile tissue, but is without effect upon true hypertrophy; vascular tumefaction, also pits on pressure, similar to œdematous structures,which is not the case in hypertrophic tissue.

In all intra-nasal diseases except where grave structural lesions exist such as caries, necroses, exostoses, ecchondrosis, syphilitic ulcerations and septum perforations, the primary or local manifestations of disease frequently disappear with the inauguration of secondary affections.

It is of frequent occurrence to find a hypertrophic rhinitis involving the inferior and middle turbinates to a degree of almost complete occlusion of the nasal fossæ, in a patient who is seeking relief from a bronchial asthma, gastritis, neuralgia, rheumatism or anæmia, when in fact, the information of the existence of a primary intra-nasal disease will be a very great surprise to the patient, who, notwithstanding the fact that the nasal fossæ may be almost completely obstructed from chronic hypertrophy or hyperplastic tissue, declares he experiences nothing wrong in the head, but alludes emphatically to a bronchial cough, or a gastric distress, soreness or distention, or to various areas of muscular soreness or neuralgic sensations, or perhaps, to subscapular or lumbar pains, etc., so that the sufferer's attention is frequently directed from a primary disease, to the distressing subjective symptoms of secondary affections.

The direction in which the secondary disease may extend, will be largely dependent upon conditions,such as inheritance,dyscrasia, peculiarities, predisposition, temperament, occupation,etc.

A normal structure with its perfect performance of function, constitutes the physiological standard of health. Pathology begins by deviation from the normal processes, and relates exclusively to morbid or unnatural conditions in living structures. In other words, it is altered physiology and can only exist in living matter.

The first or primary deviation from the normal standard, upon exposure, is vascular disturbance, and stagnation of blood in the mucous membrane and erectile tissue of the nasal cavity. This leads to swelling, redness of the parts, with increased secretion of mucus, and as the inflammation thus induced subsides, it leaves a slight hypertrophy and irritability.

The repetition of these phenomena, with repeated attacks of colds, coming and going, extending over a period of years, will in most individuals, establish a chronic rhinitis,or naso-pharyngitis, commonly termed post-nasal catarrh.

The continuous and excessive formation of mucus gravitating and trickling down from the post-nasal space into the pharynx, there to be dislodged mechanically and swallowed along with food and drink, will, in due time, initiate pathological fermentation of the gastric contents. The acrid and irritating effect of fermentation products upon the gastric mucous membrane and its glandular structures, will if allowed to persist, establish a chronic gastritis.

In the passage downwards the chyme, with its pathological fermentation products, will in like manner develop intestinal fermentation, irritation and inflammation, and if the cause remains operative, will, by continuous repetition of this abnormal condition establish chronic duodenitis, enteritis, and their consequences.

It matters not how much an individual can eat, if the gastric and intestinal mucous membrane is unable to digest and absorb it—nutrition will of necessity be seriously impaired, and the living bodily structures be deprived of their physical and vital power.

Not only will the system in general suffer the effects of inanition, but additional depression and exhaustion is superinduced from contamination of the blood with mucoid poison, leucomaines, peptotoxines and the products of bacterial and pathological action.

But the function of the digestive tract is not only impaired for digestion and absorption, but it is equally embarrassed in its eliminating activities for the removal of waste products from the system.

The existence of such a chain of morbid derangements upon the system, may eventuate in any of the following conditions, viz.: anæmia-chlorosis, leucocythemia, copræmia, neurasthenia, neuralgia, rheumatism, abscesses, furuncles, carbuncles, eczema, etc., and if a latent strumous tuberculous or syphilitic dyscrasiæ exists, it may be speedily aroused into energetic morbid action, the effects of which further exhaust the system and complicate pre-existing conditions.

Obstructive nasal abnormalities, as polypus, structural stenosis, hyperplasiæ of the turbinates, with vascular tumefaction of the erectile tissue, hypertrophic rhinitis, fibroid growths, post-nasal adenoids, traumatic septum, deflections, etc., are seriously instrumental in the development of inflammation of the mucous membrane of the larynx, trachea and bronchial tubes, by reason of failure in elevating the temperature of the inspiratory current of air to that of the blood, and further by insufficiently moistening the ingoing current, and improperly sifting and freeing it from mechanical irritants.

So that in the complete or partial obstruction, where buccal respiration is compulsory, the air reaches the deeper respiratory passages, at too low a temperature, and in too dry or too impure a condition.

Hence intra-nasal disease stands in causal relation, not only to secondary diseases of the intestinal tract, but also contributes in no small degree in the development of laryngeal, tracheal and bronchial inflammations.

Obstructive nose diseases, are also influential in the causation of various neuroses, such as asthma, paroxysmal sneezing, hay fever and chorea; while catarrhal and general fevers are not infrequently produced from the same cause.

In alluding to the general prevalence of mucous membranous inflammation, both in Europe and in this country, and the great similarity of the endemic form: also the peculiar tendency, and the predisposition which catarrhal subjects exhibited during our late epidemic of la grippe, in contracting the latter with greater frequency and severity than individuals possessing healthy mucous membranes, leads me to believe that there exists some relationship or affinity between the two affections. In substance the two diseases differ only in the following particulars, viz.: mucous membranous inflammation is more generally endemic, chronic and mild, except where the chronic form is aggravated from exposure to cold into an acute condition, while in la grippe the onset is usually sudden, acute in its course with tardy convalescence, intense in its symptomatology, prone to complications and epidemic in form.

In their pathogeny they resemble each other in this particular, that there is present in both a neurotic and an inflammatory factor; that in both there exist the characteristic features of acute coryza, plus the general febrile disturbance. In la grippe, the lesions are those of catarrhal inflammation of the mucous membrane of the eyes, nose, ear, throat, larynx, bronchi, stomach or intestines; while in simple catarrhal inflammation the process is limited, showing no disposition to invade all the mucous membranes simultaneously. In influenza the severity differs in each locality and in the person attacked; in some the bronchial effects are the most severe, while in others the gastric symptoms are the predominating manifestations. La grippe in itself has not proved to be generally fatal, but increases the mortality of other diseases, thus raising the general death rate. The attacks may be repeated in the same individual while the epidemic is raging, by an ordinary exposure to cold, as in common mucous membranous inflammation. No specific microbe or bacteria has as yet been demonstrated to exist in either the endemic or epidemic form of the disease, so far as I am aware. Although fifteen or twenty different microbes of no acknowledged specific importance have been observed to infest mucous membranes.

To the following authors I am especially indebted for much valuable information in the study of rhinology, laryngology and otology, viz.:

The late Sir Morrell Mackenzie, London; McBride, Edinburgh; Greville MacDonald, London; Francke H. Bosworth, N. Y.; Beverly Robinson, New York; Sajous, Philadelphia; Meyer, Michael, Hamburg; Elsberg, Hack, Freiburg; Beard, New York; Lennox Browne, London; St. John Roosa, New York; Albert H. Buck, New York; Scheck, Munich; Schneider, Cologne; Krause, Berlin; Mygind, Copenhagen; Dundas Grant, England, and others.

AN IMPROVED GALVANO-CAUTERY SNARE; ITS USE IN THE NOSE AND THROAT.

Read in the Section of Laryngology and Otology, at the Forty third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

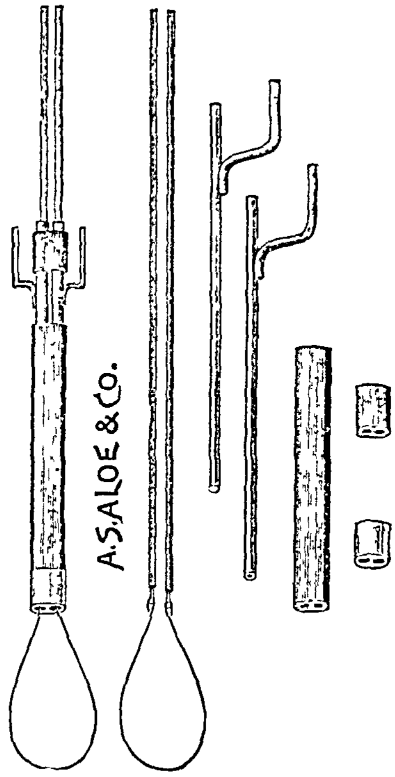
BY HANAU W. LOEB, A.M., M.D.,
OF ST LOUIS, MO.
PROFESSOR OF DISEASES OF THE NOSE AND THROAT, MARION-SIMS COLLEGE OF MEDICINE; LARYNGOLOGIST TO THE MISSOURI PACIFIC AND M. K. AND T. HOSPITALS; SURGEON TO THE NOSE AND THROAT DEPARTMENT OF THE MARION SIMS HOSPITAL AND THE GRAND AVENUE FREE DISPENSARY.

There is a just demand on the part of the medical profession for instruments which fulfil every requirement on the score of precision, efficiency and cleanliness, and just as nearly as an instrument approaches these essentials, so nearly perfect does it become. Furthermore, any change in an established instrument, which causes it to approximate this ideal condition of things, constitutes an improvement which merits adoption.

To any one who has used the galvano-cautery snares now in vogue, the thought must often have been presented that, in spite of the many advantages to be derived from their use, they exhibit many drawbacks which, long since, should have been overcome. So great, in fact, have these shortcomings appeared, that many have discarded the galvano-cautery from their armamentarium, and have adopted instead the cold snare of long ago.

A very considerable experience in the use of the galvano-cautery snare, has caused the writer carefully to consider the evident disadvantages, and, as a result of the formulation of his thoughts in this direction, the instrument now presented to the Society was suggested.

In its construction, the instrument is very simple, being made with a view of permitting perfect cleanliness. True, the old snares were thoroughly aseptic so far as the wire was concerned; for that, becoming red-hot, would naturally destroy all germs in contact therewith. But thorough asepsis or even ordinary cleanliness is precluded, *in such an instrument*, from the fact that, the canula being wrapped with silk or cotton thread, a drop of blood or a particle of secretion could not be entirely removed, and therefore constituted a first-class breeding medium for all sorts of bacteria. To obviate such a reasonable drawback, the instrument here presented has been insulated with hard rubber, which can be removed with ease from the canulæ at any time and boiled.



The canulæ themselves are readily removable from the other parts of the instrument, and hence are amenable to thorough aseptic preparation. They are a trifle larger than the canulæ ordinarily in use, but this does not in any manner affect their utility.

Another inconvenience, or rather expense, is the great length of the platinum wire which all previous snares necessitate; the average required being about 15 inches, quite a costly item when often broken. In the writer's snare only 3 or 4 inches are necessary. This result is accomplished by passing through each canula a stout copper wire containing an eyelet in its flattened end. Into this small opening the platinum wire is inserted and the ends bent so that, when the wire is pulled into the canulæ, it cannot escape. There is less inconvenience in threading this little eyelet than in passing the wire through the old canulæ.

An ivory tip similar to those for some time in use, and which is freely separable, completes the instrument.

The snare is applicable to the slide handle made by the McIntosh Battery and Optical Co., Chicago, Ill., from whom, as well as from A. S. Aloe & Co.. St. Louis, Mo., the snare may be procured.

The advantages of such an instrument, so manifest upon examination, have been amply and clearly demonstrated in actual practice. They may be stated as follows:

1. Cleanliness, as already detailed. Every portion is removable, the rubber insulator, the two canulæ, two copper wires, the platinum wire and the ivory tip; it is therefore easy to treat them as is usually done with all proper surgical instruments prior to operation. One may readily appreciate the greater satisfaction to the surgeon when he operates with an instrument which he is morally certain is clean, than when he knows that it can never be entirely free from the objection of uncleanliness.

2. Less expense. The platinum wire is not so readily broken, and when it is, may be replaced at a trifling cost.

3. The instrument is firmer, and therefore more easy of manipulation and use.

4. The current required is beyond a doubt considerably less. I have verified this a number of times, and when my storage battery has been out of order, I have, on a number of occasions, used one of the cells, instead of the two which I have found necessary with all other snares.

5. There is no danger of short-circuiting the current. This difficulty with other snares is by no means uncommon; for it not infrequently happens that when a body is engaged and the wire drawn taut, no current passes through the wire and therefore no action results. This is due either to connection of the wires below or to the absence of any electricity passing from the canulæ to the wire above. Such a condition of things is manifestly impossible in my instrument, in which the connection is made and maintained by means of the copper wire and is not at all dependent upon the canulæ, at their orifice.

The improved snare should increase the range of application and use of the galvano-cautery snare in the nose and throat, for it renders operations safe, certain and reliable procedures.

In removing tonsils, more than in any other particular, is this exemplified. Some six months ago I read a paper before the St. Louis Medical Society, describing the operation of removal of hypertrophied tonsils by means of the ordinary galvano-cautery snare. The use of this new snare has fortified my opinion that this is the safest and most satisfactory method for their removal. Tonsils in all conditions of hypertrophy, except when they are thoroughly impacted between the pillars of the palate (even then a small portion may be removed), are excised with more precision and with less danger and inconvenience than by any other method, while pain and the time required are not increased.

The *modus operandi* is simple. After applying a solution of cocaine to the mucous membrane, in order to render it insensible to the presence of the wire and moderately to anæsthetize it, the tonsil is drawn out from between the palatal pillars by means of forceps, and the snare is engaged so that as much of the tonsil may be removed as is desired or desirable. One need never fear that hæmorrhage will result in the adult, or that a portion of the palate in children will be accidentally removed. Bleeding never follows and healing is an uninterrupted sequence. The ear pain and the inflammation resulting from snare operations are no more severe or serious than from the tonsillotome operation. The snare may be used in cases where it is desirable to combine with the cauterization of the tonsil the removal of a small portion of the organ.

Of late, I have been using this snare in removing the uvula, instead of the scissors as I formerly did. The uvula is allowed to drop into the loop, the wire is drawn tight, the current turned on and the uvula removed, no forceps being necessary. I have noticed that in the twelve cases upon which I have thus far operated, the patients were able to eat at the succeeding mealtime, a rare occurrence in previous operations. The explanation would appear to be that the forceps or forks of the uvulotome draw down the mucous membrane so that more of the mucous membrane is cut away than of the muscular tissue, whereby a considerable portion of the latter remains exposed, making the whole organ, very naturally, exquisitely sensitive. Again, the stump, after the cautery operation, is more even, no hæmorrhage takes place and recovery is more rapid.

In the nose, of course, the snare is indicated wherever the old instrument could be used; in the removal of nasal polypi, portions of mucous membrane and of the turbinated bones, it suggests itself. From the certainty of its action and its advantages already given, it should displace the cold snare and the forceps in the removal of polypi—its action is quicker, no hæmorrhage occurs and recurrence is more infrequent. Besides, there is no need of after cauterization as when the cold snare alone is used.

Incidentally I may state that I am having all my cautery points covered with hard rubber instead of the thread or silk which have so long been obnoxious to me on account of the impossibility of keeping them clean. In this way a possible evil is overcome.

In conclusion, I desire to express my thanks to Mr. Lou P. Aloe for kindness and consideration in the development of the instrument which it has been my pleasure to present to the Association.

Since the foregoing was written the following communication was addressed to the writer:

"The snare is certainly possessed of advantages over the ordinary forms, notably among which are greater ease with which it can be cleaned, economy in platinum wire and less ampèrage required in heating. This latter feature showed very plainly when testing yesterday and to-day a new device for the use of the Edison current in galvano-cautery. Twenty ampères of current would not satisfactorily heat the ordinary form of snare; 10 to 15 brought your snare up to proper heat. (Signed) McIntosh B. and O. Co.,
C. Alfred Smith, Sec'y."

Quod crat demonstrandum.

Sir Joseph Lister, having reached the age of sixty-five, the age-limit by the regulations of King's College, Edinburgh, has retired from the clinical lectureship.

COMPRESSED AIR AND SPRAYS IN DISEASES OF THE NOSE, THROAT AND EAR.

Read in the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held in Detroit, Mich., June, 1892.

BY SETH SCOTT BISHOP, M.D.,
OF CHICAGO.

The use of compressed air in the treatment of affections of the nose, throat and ear is so indispensable and universal that it is somewhat remarkable that there should be a poverty of definite literature on the subject of its dosage. Especially is this true with reference to its use in ear diseases, in the treatment of which it is a powerful agent for good or evil.

Among ten of the most prominent authorities on the ear only two give definite information on its proper dosage.

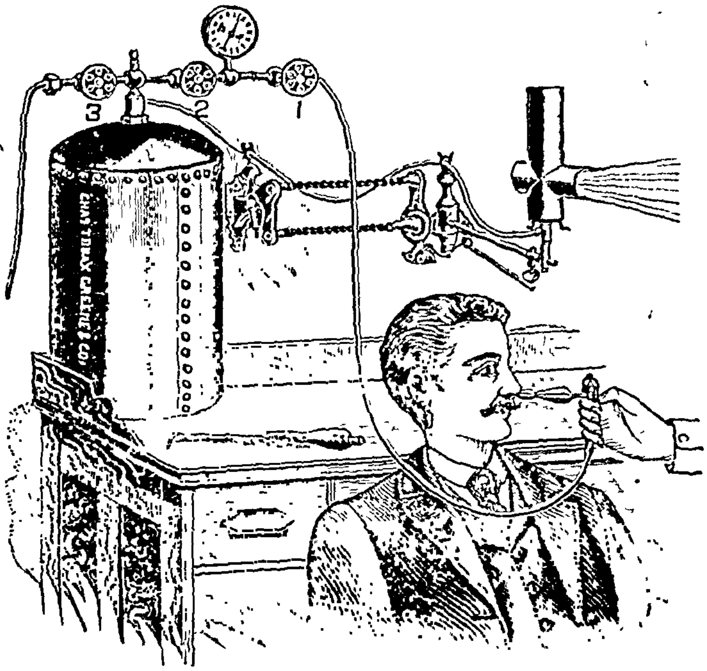
By a series of experiments with the compressed air gauge I have found that the maximum amount of pressure that can be obtained with a Politzer air balloon of the capacity of eight fluid ounces is six pounds; with the six ounce bag the pressure may be made to reach ten or twelve pounds. The difference in favor of the smaller bulb represents the greater advantage one has in grasping a small object. This amount was the maximum obtainable by an unusually strong hand, accustomed for years to compressing air bags handled at the greatest advantage for leverage, that is, with the larger end of the balloon between the thumb and strongest fingers, and the tapering end under the third and fourth, or weakest fingers. As the reverse method is practiced by many aurists, much less force than six and ten pounds must result.

Politzer speaks of ten and twelve ounce bags which are manipulated in Vienna by pressing them against the operator's side, but they are not in our markets. The Gruber balloons, with the opening or air valve at the larger end, might possibly accumulate more force than I have mentioned, by repeatedly compressing them, but on account of the valves being imperfect, or soon becoming useless, I have discontinued their use. Professor Gruber himself prefers the bulb having a perforation in the end to be covered and compressed with the thumb. I have not experimented with this kind, for one could not be found.

The rubber bulb usually supplied by the Davidson company for hand sprays and inflators can be made to exert fifteen or even eighteen pounds, but not by a single compression. However, it is not practicable to employ more than fifteen pounds with the $\frac{3}{16}$ inch rubber tubing ordinarily supplied with Buttle's inflators. A higher pressure distends it, and eighteen pounds ruptures it with a loud report. The thick, firm, white tubes accompanying the De Vilbiss atomizers will stand more, for I have tested them with forty-five pounds without even distending them.

The force necessary to spray the nose and throat is not great. Eight pounds will project continuous sprays of watery solutions or lavoline with sufficient force from the Davidson atomizer. Parenthetically I wish to explain that when I say lavoline I do not mean lanoline, as many journals have made me say. Lavoline is a purified liquid vaseline. About twelve pounds' pressure is needed to produce a continuous and copious lavoline spray from the De Vilbiss atomizer, and it requires thirty or forty pounds to throw a spray of unheated glycerole of tannin.

In adapting the improved compressed air apparatus to the treatment of the ear I have endeavored to devise some means of *determining and controlling* the force and volume of air, or the dosage. To illustrate the necessity for this I may quote one of my assistants as having recently reported a case of rupture of the drumhead by an aurist who was using compressed air *without an air meter to gauge* the amount of force used. The employment of compressed air in otology should be placed on a scientific basis. Guessing won't do. Such a powerful remedy as we have stored in our air reservoirs with a hundred pounds pressure to the square inch should be administered with care, skill and accuracy. It can be demonstrated that this is possible.



As the accompanying illustration will show I have accomplished this by placing a pressure gauge between two valves *on the escape* pipe of the air receiver. This arrangement utilizes the gauge for registering not only the air pressure in the reservoir but also the force of the current of air while it is escaping through the cut-off of the treatment tube.

The whole apparatus used in my experiments, excepting the cut-off, was made by Chas. Truax, Greene & Co., of Chicago. The cut-off used is the Davidson pattern. The only fault in its construction is the violation of the important principle that a right angle should never have a place in a compressed air tube. It is obstructive and should be replaced by a curve.

The meter is used as follows: By opening the outer right hand valve marked 1, by turning the wheel to the left one-fourth of its circumference, pressing the thumb valve of the cut-off and opening valve 2, gradually you may obtain any number of pounds' pressure desired at the cut-off, from one to one hundred. To use ten pounds: with the cut-off and valve 1 open, turn the valve 2 until the index needle runs up to 10. As long as the cut-off remains open the needle indicates 10 pounds. If you close the cut-off the needle rises to indicate the whole number of pounds in the reservoir. Now if you fit a spray producer to the cut-off and open it, the first impulse of the column of air, which is small in volume, is expended in filling the atomizer and starting the spray. In using the nasal bulb of Buttle's inflator for treating the ear, the first impulse is expended in filling the nasal and superior pharyngeal cavities in addition to inflating the middle ear. The volume of air is so small that the needle drops down to 10 at once and remains there as long as the cut-off is kept open. If no more than this amount is desired the cut-off should be opened before the current is turned on and valve No. 2 should be slowly opened until the needle indicates the number of pounds required. No greater pressure will then be exerted unless the cut-off valve is closed.

When it is desired to interrupt the air current for the purpose of producing to and fro movements of the membrana tympani and ossicles, or to throw jets of volatilized medicine or sprays into the tympanic cavity, it is a simple matter to control the pressure in this way. Let us assume that we want to use, with the nasal-tipped inflator I have adapted to this purpose, three atmospheres, or about forty-five pounds. Valve 1 being opened, apply the cut-off to the nasal bulb containing the medicine on sponges; open the cut-off; turn on twenty pounds with wheel 2 and then close cut-off. The needle rises. Now if the inflator is inserted into the nostril with the patient's nose firmly closed and cheeks fully distended, the instant the cut-off is opened, the needle runs down to 20. Close the cut-off, and the needle mounts to 45 pounds. Open the cut-off at that moment and the needle descends again to 20; close the cut-off and the needle rises; the instant it touches the 45 pounds mark, open the cut-off again and so on; repeatedly opening and closing the cut-off will give repeated impulses at any given pressure.

The resistance offered by the sponges is small—less than $\frac{1}{3}$ of an atmosphere.

A little practice will enable anyone to measure the doses skilfully and to give effective treatments without fatigue.

If very rapid interruptions are required, valve 2 should be opened more freely than in the example given. For forty-five pounds' maximum pressure, about thirty pounds should be allowed for the uninterrupted current. My experience with this method indicates that not more than sixty interruptions per minute should be made in order to produce decided vibratory movements of the drum head and ossicles.

The dose of air for ear treatment varies greatly in different individuals. While fifteen pounds might endanger the continuity of an infant's drum head or one greatly weakened by disease, or the thin cicatricial membranes closing old perforations, I have often applied from sixty to ninety pounds to old thickened and hardened drum heads without doing them the kindness of bursting them.

It is evident that if it requires fifty to eighty pounds in some cases to propel sprays into the middle ear it follows that in such instances rubber air bags are insufficient, for they do not average more than six to fifteen pounds. But with high pressure only a small volume should be used. I would propose the following rule to keep the operator within the limits of safety: The higher the pressure the lower the volume should be. If the density of the air is greater than one wishes to use, even with a minute volume, it is easy to avoid the high pressure when using the nasal tipped inflator by leaving the opposite nostril open during the first impulse, until the needle descends to the proper point. This allows the surplus air to escape by the opposite nostril. The same purpose is accomplished with the catheter by holding the catheter tipped inflator a little withdrawn from the mouth of the catheter while the cut-off is first slowly opened. The surplus pressure then escapes at the junction of the inflator and catheter.

The volume should be proportioned to the density with care in cases of atrophied soft palate so as not to strain the muscles of the throat by too powerful inflations, especially if they are subject to rheumatic sore throat.

It serves a convenient purpose to instruct patients to raise one or both hands every time they feel that one or both ears are inflated. This obviates the necessity of frequently using the auscultating tube.

The warnings against the danger of rupturing the membrana tympani by Politzerization have been freely sounded. I do not know that I have ever ruptured a drum head by compressed air, while I have seen a considerable number that were torn or perforated by blows on the ear. Even in men employed in caissons of tunnels, bridges, etc., where they are compelled to work in an atmosphere condensed under a pressure of forty to sixty pounds, it is rare to find a ruptured drum head. This may be owing to the fact that they are instructed to inflate the ears so as to equalize the pressure on both side of the membrane. In this connection it must not be forgotten that there is always the natural atmospheric pressure of nearly fifteen pounds on the outer aspect of the drum. Notwithstanding this an eminent otologist has asserted that drum heads have been lacerated by Politzer's method.

Professor Politzer says: "During thirteen years only fourteen cases of ruptured drum heads are known. In the case of a normal membrana tympani a pressure of forty-five to sixty pounds is required to cause rupture. In treatment, however, we apply only a pressure of about eight pounds." If there were any fear of rupture, it could probably be prevented by firmly pressing the tragus into the external meatus.

As compared with the Valsalvan method the application of medicated nasal-tipped inflators as I have fitted them to the compressed air apparatus makes an effective topical application of various medicaments possible without any active exertion on the part of the patient. In the Valsalvan experiment there is no medication of the middle ears, but simply a mechanical effect of moderate pressure, and a probable congestion resulting from the straining effort. A. Hartman has shown that four to eight pounds pressure by the Valsalvan method is required to bulge forward a healthy drum head. In numerous experiments the pressure averaged from twenty to twenty-six pounds in males, and from fourteen to twenty-two in females. But owing to swelling of the Eustachian tube or contained secretions this experiment often fails.

The unwisdom of advising patients to practice the Valsalvan experiment has often been demonstrated by individuals who have come under my observation with a history of rapid failure of hearing owing to their habit of carrying the aurist's instructions to excess.

Politzer's method is far preferable. He says: "The pressure for the application of my method in practice varies as a rule between fifteen and sixty pounds, which can easily be produced by a compression of a pyriform India rubber bag capable of holding ten to twelve fluid ounces. Only in a few cases is it necessary to apply a greater force."

The six ounce bag is as large as can be conveniently compressed by the hand alone, and the compression of these very large balloons between the hand and knee or side of the surgeon does not seem to fulfil the ideal of an artistic performance.

A decided advantage to both patient and operator in the adaptation of the inflator to the compressed air apparatus lies in the fact that it renders it possible to treat most aural patients without the Eustachian catheter.

The sponges of the inflator may be saturated with solutions of camphor-menthol or other remedies in lavoline, and sprays of these medicines can be propelled through the nose and Eustachian tubes into the middle ears with ease and certainty in the majority of cases. This diminishes the danger of syphilitic infection and of irritation of the Eustachian orifices.

Often gentle pressure will accomplish this. Indeed patients sometimes feel a spray enter the ear from an ordinary hand atomizer, especially when the cheeks are distended. By turning on the current of air gently, and gradually increasing it, the permeability of the tube may be re-established by a weak air pressure more easily than by a sudden forcible current.

In practicing this method I have usually found the results most satisfactory when the patient assisted by inflating the cheeks and keeping the lips firmly closed. At the instant the nasal cavities become filled from the inflator the velum palati and base of the tongue press automatically upward and backward, completely closing the post-nasal space. I have now under treatment a case in which the soft palate is absent through ulceration, but the tongue so thoroughly shuts off the nasal cavities during this experiment that fifty pound's pressure is concentrated on the right middle ear while the left is closed. Nevertheless there are some instances in which the ears are more readily inflated during the act of swallowing.

It has been suggested that these forcible air currents might convey discharges into the mastoid cells, but Dr. Michael has "proved that, especially with the application of strong currents of air, the secretion in the tympani cavity is always propelled into the external meatus and not into the mastoid process."

Occasionally one sees a case in which the current of air from the nasal-tipped inflator fails to open the Eustachian tube. Probably the anterior lip of the orifice of the tube is pressed by the air more firmly than ever against its fellow, closing it like a valve. A case now under treatment resists ninety pounds with the nasal bulb, but fifty pounds pressure carries camphor-menthol and lavoline into his middle ears through the catheter.

Treatment by the catheter is accomplished with the same inflators I have already mentioned, the catheter tip being substituted for the nasal bulb. The sprays are thrown through the catheter in interrupted jets without imparting discomforting movements to the catheter, a feat well nigh impossible in the practice of Politzerization with the air bag fitted with the hard rubber tube which is inserted directly into the catheter, and without any intervening flexible tube, as the custom is in Vienna.

Proper precaution should be taken to prevent dust from entering the air reservoir, although, by the methods I practice all air entering the ears is filtered and medicated.

Finally, these methods make the middle ears nearly as accessible as the nose and throat for treatment with the various volatile remedies and sprays.

70 State Street.

Discussion.

Dr. Richardson stated that he did not wish to doubt Dr. Bishop in his statements made in his paper, but he could not see how it was possible to use a pressure of over forty pounds without causing injury to middle ear and rupture of membrane. He was only explainable from his standpoint by the possible loss of pressure in the passage of the column of air through tubes, sponge, nasal cavity and Eustachian tube until pressure was reduced to that usually obtained by the ordinary method of Politzerization. Four years ago, at the meeting of the American Medical Association, at Newport, he reported several cases of inflammation produced in the middle ear by the use of high pressure in atomization and it was the universal consensus of opinion that such condition often arose, under these circumstances, and instances were cited by several present. Even by the use of the low pressure obtainable by the use of the Politzer bag rupture of membranes did take place and two such cases had occurred in the doctor's practice. Of course these cases were not normal membrane, nor is Dr. Bishop treating normal membranes—a pathological membrane, atrophies here and adhesion there will not stand the pressure of normal membrane. For his part he could not see how the use of such high pressure could be borne by any nose. It seemed to him that it would cause serious lesion to nasal, pharyngeal and tympanic mucous membranes. The use of even low pressure is often attended with great pain, how much more so must be these pressures of 50 to 90 pounds.

Dr. Richards asked Dr. Bishop if the reporting such high pressure, under his authority, might be misunderstood by others, who resorting to these methods, not possessing his skill, cause rupture of membranes and serious lesions of nasal cavities and ears.

Dr. Seiss has only obtained five pounds' pressure from Politzer bag, and has seen rupture of the drum from this force. Regards 12 pounds as the maximum force to be employed in nasal sprays. Thinks a pressure of 50 pounds most dangerous and quite unjustifiable in treatment of Eustachian tubes or nasal mucous membrane.

Dr. De Vilbiss thought that great care must be taken in regulating the pressure. Perhaps Dr. B. had lost more force than he supposed in the transit of the air from reservoir to middle ear.

Dr. Price Brown, Toronto, had not been able to administer sprays of cooling solutions of a stronger air pressure than 12 pounds to the inch without producing hæmorrhage from the nasal mucous membrane. With sprays of albolene and glycolin as a menstruum 15 pounds pressure to the inch could be used and without hæmorrhage, but not a higher pressure.

Dr. Randall said the question was not what pressure was used *at* but *in* the ear. The manometer connected with the external canal was the sole means of determining the pressure actually employed. High pressure air in small volume might penetrate the Eustachian isthmus, but would instantly be reduced by expansion in the tympanic and mastoid cavities. On the outer surface of the drumhead the diver at a depth of 15 feet finds a pressure of 7 to 8 pounds painful, and 10 to 12 pounds hardly bearable. Yet the movement outward of the membrane would be greater and a higher pressure tolerated or relieved by distension.

Dr. Thomas Hubbard, Toledo :—Having conducted some experiments in this line, and having arrived at conclusions that seem to be at such contrast with those of Dr. Bishop, it becomes a duty for me to speak on this subject, since I believe that his statements are positively dangerous, and contrary to actual facts and conditions. For instance: he states that he considers a pressure of 15 pounds safe for inflation of middle ear of an infant. In my experience a pressure of one pound is too great for a child of some years. His range of pressure for the adult is 50 to 90 pounds. This I would divide by ten and yet divide it again by two. My range of pressure is between one and two and one-half pounds for the adult. I am referring to the air pressure gauge in connection with the tube conveying the air to the nostril, and of course mean pounds per square inch.

I would therefore challenge every estimate that he has used in the above statement, and would respectfully refer the doctor to certain facts in the physiology of respiration for proof in part. A strong robust adult can by forced expiratory effort raise the air-pressure in an accurate air-gauge from 3 to 3½ pounds. Therefore, by the Valsalva method we are right in inferring that this is about the maximum pressure obtainable.

Very few persons can tolerate all the pressure that they can bring to bear in this process of self-inflation without pain or rupture of the membrane. Here then, is an indication of the maximum pressure that can be safely used, namely, 3 or 3½ pounds.

The basis of the Politzer method is the fact that the Eustachian orifices are made patulous by the very act of swallowing. The doctor ignores this and consequently must employ much higher pressure than is necessary, although I cannot believe that he gets one-tenth of the pressure that he would lead us to believe.

Dr. Bishop in closing the discussion said: The gentlemen who have participated in this discussion have emphasized the point upon which I have laid special stress, that is the danger in using air from reservoirs under very high pressure without being able to determine the amount of pressure and the volume of air used. In other words, the dosage. It takes these two elements to make up the dose-pressure and volume. That is my apology for calling your attention to this very simple little device pictured in the cuts that are distributed among you. Dr. Hubbard thinks I use a dangerous pressure when I speak of 75 or more pounds. It would be dangerous in the absence of any means of controlling the amount of air used.

Does it make any difference, gentlemen, whether you use a cubic foot of air under high pressure or a cubic inch? Does it make any difference whether you throw a pebble or a rock at a pane of glass? Shall we make no distinction between a high pressure column 1-16 of an inch in diameter and one large enough to constitute a cyclone?

Without this air meter to put both pressure and volume under our entire control I would not advocate the use of high pressure. But with it one can use air from my reservoir which is filled every day with air under 100 pounds pressure to the square inch with as much safety as lies in the low pressure receivers mentioned by Dr. De Vilbiss.

Granting this, which I am prepared to demonstrate, you must concede that the possibilities of breaking up adhesions and anchylosis and overcoming immobility of the ossicles and restoring the sunken drum membrane to its normal position, are greatly increased.

Since it requires 4 to 8 pounds to bulge forward a healthy drum head, many times the pressure is necessary to affect these old thickened, leather-like membranes that have been held retracted by anchylosed ossicles for years. I have often removed such membranes and have found them thick, tough and sometimes gritty from chalky deposits. What effect can you expect to produce on such ears by one pound of pressure on the inner side of the drum head while there is constantly an opposing atmospheric pressure of fifteen pounds to the square inch on the outer side of the drum?

The gentleman at my right speaks of having had inflammation and even rupture of the membrana tympani from the use of Politzer's method. I have had no such experience, but I do not make use of strong inflations in children or in the acute stage of inflammation.

One of the two principal conditions upon which I predicate the safe use of high pressure seems to have been forgotten in the discussion. That is the ability to control the amount or volume of air used at each dose. While I use only the minutest column of air under high pressure, I am able to cut off a dose of this column, or subdivide it, so as to limit it to a fraction of a cubic inch. You can open the valves 1-32 or 1-64 of an inch if you like.

This air meter may be compared to the milliampère meter which makes it possible to obtain therapeutic effects from electricity which would be otherwise impossible or dangerous, because the dosage can be determined and definitely controlled.

MUCHOLD reports a case of Grave's disease in which he removed the posterior half of one of the inferior turbinate bones with the galvano-cautery, with immediate improvement in all the symptoms except the goitre, which was, however, readily reduced by a mild galvanic current. He suggests the possibility of the disease being sometimes due to some reflex disturbance.

SOME OBSERVATIONS UPON EXCISION OF THE MEMBRANA TYMPANI, AND THE TWO LARGEST AUDITORY OSSICLES.

Read before the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY CHARLES H. BURNETT, M.D.,
OF PHILADELPHIA.
AURAL SURGEON, PRESBYTERIAN HOSPITAL, ETC., ETC.

A year ago I read in this Section a paper upon excision of the membrana tympani and the two largest auditory ossicles, in which two sets of indications for the operation were set forth as follows:

1. The deafness, tinnitus and vertigo of chronic catarrhal otitis media, especially when adhesions exist between the membrana tympani and the promontory in the inner tympanic wall, or when there is evidence of synechiæ between the ossicles.

2. This operation is indicated in the suppuration, deafness, tinnitus, vertigo, headache, and recurring earache of otitis media purulenta chronica.

Conclusions regarding the results of the operation in cases of chronic catarrhal otitis media were presented as follows:

1. The operation of excision is attended with no bad results, even if it do no good, and its effects are superior to massage, mobilization, plicotomy, etc., etc., applied to the membrana and the ossicles.

2. The most constant result of the operation is a relief from a sensation of pressure and fulness in the ear.

3. There is generally a more or less prompt, entire and permanent relief of tinnitus and aural vertigo (so-called Ménière's symptoms).

4. The least frequent and permanent result is improvement in hearing. Sometimes, however, this is marked. In some instances the improvement in hearing is maintained after regeneration of the membrana tympani. In those cases of chronic catarrh of the middle ear, in which everything else has been tried without benefit, it would seem rational that the patient should have the chance of improvement offered by this harmless operation, for harmless it certainly has been in all my cases, even if the benefit has been slight or *nil*.[1]

Conclusions regarding the results of the operation of the excision of the membrana tympani and the two largest ossicles, in chronic purulent otitis media.

1. The operation has not failed either to greatly diminish or check the suppuration in all the cases of chronic otorrhœa in which the writer has applied it.

2. In attic cases with normal atrium, the sole perforation being in the membrana flaccida, this operation has shown itself to be the *only* sure means of cure. I would add that in attic cases, with diseased atrium and with perforations, both in the membrana flaccida and membrana tensa, this operation has also effected a radical cure after the disease had defied all other remedies.

3. By this operation in chronic purulent otitis media, especially in cases in which the perforation in the membrana tensa is comparatively small and while the disease is limited to the drum cavity, the

---

[1] Since writing this paper, I have been forced to conclude that in many cases of chronic catarrhal otitis media better results can be obtained by the removal of the stapes, as well as the incus. In some of such cases it may be well to let the membrana and malleus remain.

suppuration can be directly reached and treated and drainage improved by the removal of the membrana tympani and malleus, before the purulent disease has attacked the posterior portion of the drum-cavity and the antrum. Thus mastoid inflammation, and necrosis, sinus-thrombosis, pyæmia and cerebral abscess are prevented.

4. If any hearing exists before the operation in purulent cases it invariably improves after the excision of the necrotic membrana and ossicles. Vertigo, headache, tinnitus and the attacks of ear-ache from gatherings, so common in chronic otorrhœa, are entirely and permanently removed. The general health which is nearly always impaired in these cases by a form of mild chronic septicæmia from the chronic purulency in the ear, is always improved by the antiseptic effects of the operation which removes the septic nidus and makes it possible to render the drum cavity entirely aseptic by the improved drainage and direct medication.

I have seen no reason for changing any of these conclusions; on the contrary I am more firmly convinced of the great benefit especially in chronic purulent cases, to be derived from the operation of excision of the necrotic membrana and the diseased malleus and incus. The latter bonelet, however, is readily destroyed by purulency in the drum-cavity and hence, in chronic cases, is rarely found when the operation is performed.

Instruments.—Straight instruments have been found preferable to those set at an angle with the handle. As the operation is one largely performed by fingers the straight instrument is more easily managed by the slightest movement between the fingers. The tactile impressions conveyed through the easily-moved straight instruments are much more definite and useful than those conveyed through the awkward and angular instrument-handles, which have to be managed by hand and wrist to some extent and hence cannot be so delicately manipulated. The incus-knife of the writer, consisting of a short blade set at right angle to the shaft, can be used as both knife and hook with which to pull out the incus after it has been detached, even when it has slipped back out of sight towards the mastoid cavity.

The recumbent position favors the slipping backward of the incus after it is detached from the stapes, and especially if it be already detached from the malleus. Therefore it is much more convenient for the operator to lift the head and shoulders of the patient up as high as the anæsthetic state will permit. This can be done very easily by having the head- and shoulder-portion of the operating table hinged so as to lift it to any angle desired.

I would merely mention here that I have always employed ether in my operations, the illumination of the ear being effected by a six-volt electric head-lamp supported on the forehead.

Teeth.—The teeth should be in good condition before the operation, especially when performed for the relief of the symptoms in a case of chronic aural catarrh. In a case of this kind operated upon last November (1891), and in which iodoform blown into the ear immediately after the operation, and renewed several times soon afterwards, seemed to prevent regeneration and in which the improved hearing and diminution in the tinnitus were maintained, a diseased and painful tooth, apparently caused irritation in the operated ear.

The patient sought the aid of a dentist for relief of toothache in January, two months after the operation. The tooth was extracted roughly, as it appeared to me. Pain in the jaw and throat ensued with ear-ache and suppuration in the ear in which the excision had been performed. During the muco-purulent discharge which ensued, and which was followed at last by regeneration of the membrana, the patient, a woman of thirty-three, showed symptoms of secondary syphilis evidently contracted from her husband. The regeneration of the membrana tympani was not followed, however, by diminution of hearing, nor increase in the tinnitus, which had been measurably diminished by the operation. Though, in this case, the acute inflammation in the ear operated on, may have been induced by the secondary syphilis, bad teeth are competent to act prejudicially in any case of excision of the membrana tympani, and hence, they should be examined and put in good order, before the operation.

Operation on both ears.—In two cases of chronic catarrhal otitis media, one in December, and the other in January last, I excised the membrana tympani and malleus in both ears. In the first case, a woman forty-five years old, operated upon in the Presbyterian Hospital, there was no relief. Regeneration was prevented in both ears by insufflations of iodoform, retained for weeks. In the worse ear there was some reaction upon leaving the hospital and taking cold in January. This was promptly checked by iodoform insufflations and total regeneration prevented. A new membrana formed excepting a small central hole. In the better ear no regeneration has yet occurred, six months after the operation.

In the second case, a woman sixty-five years old, operated upon in the Presbyterian hospital, in January last, both membranæ and mallei were excised without relief. The woman was the subject of great cranial neuralgia and debility from hard work. The operation afforded no relief. Regeneration was prevented in this case by the use of iodoform insufflations. In March of this year, three months after the operation on the ears, the patient left the hospital, without regeneration of the membranæ. She went to work, took cold, and early in May suddenly developed in the worse ear an acute otitis media, with pain and copious discharge. The case has been readmitted to the Presbyterian hospital and is now under observation. Regeneration, at least partial, will ensue. Inflammation occurring in these cases in the worse ear, though months after the operation, would seem to indicate that 1, in all chronic aural catarrh there is an inclination to acute suppurative processes in proportion to the degree of sclerosis, or trophic change; and 2, that this tendency is always likely to be a menace to success of the operation in chronic catarrhal otitis media; 3. The only hope of combating this tendency, so far as my experience extends, lies in the immediate application and prolonged retention of iodoform in the seat of the operation.

In two cases of chronic catarrh of the middle ear, I have recently removed the *malleus and incus* for the relief of deafness and tinnitus. In the first case, a woman thirty-two years old, I removed May 9, 1892, the malleus and incus, and insufflated iodoform, the hearing was improved by the second day for clicking sounds and for the voice. A clicking sound could be heard twenty feet away from the ear operated on, while it was audible about half the distance in the other ear. The voice was heard a foot away in the ear operated upon, and the impact of sound was novel and somewhat disagreeable on this side. Before the operation it was a question whether isolated words were heard in this ear. The tinnitus was not materially lessened. Notwithstanding a severe reaction in the ear on the fifth day after the operation, the improvement in hearing was maintained.

In the second case, a woman twenty-four years old had complained of tinnitus and deafness in both ears, for eighteen months. In the left ear there was considerable ankylosis and tinnitus. The hearing was eighteen inches to two feet for isolated words. Some hypertrophic nasal catarrh. Tinnitus quelled for five minutes in the left ear by using the pneumatic speculum. May 13, 1892, excised the membrana, malleus and incus, and insufflated iodoform. Tinnitus was not entirely quelled by operation. No improvement in hearing the first two days. By the third day tinnitus less and hearing improved. In a week the hearing was eight and ten feet for isolated words. On the ninth day after the operation patient went to church and was able to hear better than she has for over a year. No reaction in this case by the twelfth day, the iodoform was dry in the fundus of the ear and the patient went home to another city well satisfied with the result of the operation.

The improvement in hearing when it occurs as the result of the operation in cases of chronic sclerotic otitis media, is always *progressive*. It would seem from this that the direct transmission of sound to the stapes effected by the removal of the membrana tympani, mobilizes the ossicle in an effectual manner. The passive motion thus conveyed to the stapes gradually overcomes the ankylosis which has been hindering its movements, rendering it consequently more vibratile and responsive to sound-waves. The nerve of hearing too, by the renewed reception of sound impressions thus once more conveyed to it, probably becomes more sensitive to ærial sound waves, its normal stimulus.

Results in chronic purulent otitis media.—In cases of purulent otitis media the results of the operation of excision of the membrana and the malleus are usually eminently satisfactory as shown by the history of the following case: Thomas B., aged 12 years, an intelligent lad, has suffered from chronic otorrhœa and deafness of the left ear for some years. No account of the inception of the disease could be obtained. Examination revealed a uniformly swollen, red, flat and dry membrana tympani, with a large and narrow oval perforation in the anterior inferior quadrant of the membrana very near the periphery. No signs of the malleus could be seen in the flat, even surface of the swollen membrane. Through the perforation a little muco-pus could be seen, and when this was mopped away with cotton on the holder, the granulating inner wall of the tympanic cavity could be seen and made to bleed by a touch from the probe. Hearing for isolated words in the diseased ear was two feet. At times the discharge was copious enough to appear at the meatus.

On April 12, 1892, the lad was etherized and the greatly thickened and diseased membrana with the malleus excised. No trace of the incus could be seen, or felt with probe. The membrana was greatly thickened and tough, and its inner surface was studded with granulations. The inner tympanic wall was also granular; but the hæmorrhage during the operation was comparatively slight for a purulent case, in which as a rule, the hæmorrhage is considerable for so small a field of operation. Iodoform was insufflated and the ear let alone for a day or two, when it was mopped clean with hydrogen dinoxide and more iodoform insufflated.

On April 28, a test of the hearing revealed an ability to hear isolated words eight feet from the ear operated on. There was no discharge. On May 16, another test revealed a hearing distance of twenty feet for isolated words. The inner wall of the tympanic cavity had lost its granulations and had become gray and smooth and there was no discharge. The patient was dismissed from the Presbyterian hospital where he had been operated upon, and resumed his duties in school.

THE OPERATION FOR EXCISION OF THE OSSICULA IN CHRONIC AURAL CATARRH WITH INSTANCE OF A FAILURE.

Read before the Section of Laryngology and Otology, at the forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY H. V. WURDEMANN, M.D.,
OF MILWAUKEE, WIS.

Before taking up the subject matter of my paper I would like it to be distinctly understood that I intend casting no aspersions upon aural operative procedures. My standing upon this subject may perhaps be known.[19] I refer more particularly to excision of the ossicles in chronic suppuration and in chronic aural catarrh. I have had marked success both previous to and since the one disastrous result which forms the nucleus of this paper.

Sexton,[14] Burnett,[4 5 6] Colles[7] and others in this country do not mention any bad results, from the operation occurring in their practice. The latest article[9] that I have seen relating to operative interference in chronic aural catarrh says: "With reference to surgical procedure I can truly say that in no case have I seen a bad result follow any of the operations, either immediately or subsequently, and in nearly all cases there has been a certain amount of improvement either in diminishing the tinnitus or in improving the hearing". Most papers go on in this strain and say that while we can never promise in a given case what the amount of improvement will be, we can promise that the condition will not be aggravated and that the chances for improvement are certainly favorable.[9] This was and is still, my opinion for cases that I accept for operation.

In all the literature of the subject at my command, I can discover but little mention of accidents occurring during or after the operation, and these have all been in suppurative cases. I can find, in only three instances, the admissions of but two operators, of unfavorable results upon the hearing. In 1889 Wetzel[18] reported two cases in which the hearing had been made worse, in the one where the mastoid antrum had been opened during the excision and in the other where the stapes had been interfered with. Yet the latter has occurred in other instances without ill effects and the bonelet has been bodily removed experimentally in animals whose hearing was still preserved.[3]

Reinhard,[11] of Duisborg, in a paper upon Hammer-Amboss-Excision, admits that in only one case in his practice, which however "could not be controlled," was there any malefic effect upon the hearing. In the discussion upon this paper, Schwartze[12] said that neither he nor his associates had, or had heard of a death following the operation and that he had seen no ill effects beyond paralysis of the facialis and vertigo. He claims that the former is the fault of the operator, being produced by injury to the Fallopian canal from the incus hook. This need not happen in operating for proliferous disease as removal of the incus is unnecessary.[15 17] In one case Schwartze[12] had seen vertigo, persisting for over a month, following the operation. I have noticed temporary disturbance of the sense limited to the tongue tip of same side[10] and in a case operated on two months from date of writing, although some relief was experienced from the tinnitus and deafness, there is yet complete absence of this sense in the end of the tongue on operated side. After operation for non-purulent disease suppuration is a common event as shown by reports of others.[5 11] In the year previous to the date of case reported in this paper I had excised the ossicula in six cases[19] and since that time in five more. Four of these have been for non-suppurative inflammation. In only one instance has suppuration followed. I may add that my cases are carefully chosen according to the rules laid down by Burnett[4] and by Sexton.[14]

One year ago a strong healthy man of sixty consulted me about his ears. He complained of deafness, noises in the head and vertigo for which he sought relief. He claimed that the right ear had discharged, many years ago, and since had been totally deaf on that side. For about five years the left ear had been failing until now conversation was carried on with difficulty. Status præsens:—R.E., H.D., loud sounds. Tuning fork of low pitch by aerial conduction. Bone conduction better than on other side. Drum-head retracted with chalk in membrana flaccida. L.E., H.D. Watch p-150, whisper 2 cm., voice 1 ½m. Drum-head retracted and opaque; malleus not freely movable. Eustachian tubes on both sides patulous. Has hypertrophic rhinitis and deviated septum.

I treated the nasal hypertrophy after Bosworth's[2] method and made local applications to the naso-pharynx with marked benefit. Treated the middle ear of both sides by catheter, using camphor iodin and camphor-menthol vapors for three weeks, and followed by the injection of sodium bicarbonate solution for over a week with absolutely no improvement of hearing on either side.

The tinnitus was still about the same, and despairing of improvement by other than surgical means, I suggested an operation. In July following I removed the membrana tympani and malleus under ether anæsthesia. The operation was clean and although several attempts were made to reach the incus it was not obtained. These were made by the incus hook and no reckless gouging was done. Although the anæsthetic was given by a skilled assistant the patient did not take it well, he became cyanotic at times and the progress of the operation had to be delayed. There was excessive vomiting after recovery. When he came to his senses he complained greatly of vertigo. This was ascribed to the after effects of the ether. On testing his hearing on the evening of the second day I found him so deaf as to only understand shouted words, and upon investigating the cause I was surprised to find that he was *totally deaf on the operated side*. No other reaction followed, until five days later, he had pain at night, and on the next morning an acute otitis media set in which ran its course in two weeks. For four weeks after there was an occasional mucous discharge, the tympanum being dry for days together. All this time the operated ear continued stone deaf. The after treatment for the first few days consisted in "letting bad enough alone," and after the acute attack of inflammation set in, was gentle wiping out of the canal by cotton wet with 3 per cent. boric acid solution. After several days of this a little powdered acid was blown in the ear after cleansing. Internally I gave him drop doses of tincture aconite and later pilocarpin, with no appreciable effect from the latter on the hearing. A couple of months later, when the ear seemed quiet, I commenced the use of galvanism with the result of setting up sufficient irritation in the operated ear to cause an acute discharge. This was tried several times and further treatment of that side given up as a hopeless case. During this period I had been treating the other ear by active and prolonged massage, applied both directly to the malleus by a cotton-tipped probe and by Siegel's otoscope. Also continued inflation by the catheter, etc. To our gratification this ear rapidly improved in hearing until after one month's treatment he could hear the voice at 1½ m.

About this time I sent the patient in consultation to Bishop, of Chicago, who treated him for a couple of weeks, with the idea of helping the hearing on the operated side. Dr. Bishop had better luck than I with electrical treatment, and wrote[1] me that the patient could, at the time of writing, hear the upper notes of the scale. This I observed on his return. The patient was obliged to visit New York, and while there, on the advice of Dr. Bishop, consulted an aurist by whom I understand little encouragement was given. He was placed upon specific treatment later, with no results as regards the deaf ear, which since that time has remained in about the same condition. The noises in the head ceased entirely a few days after the operation and have never returned. The loss of these, however, does not make amends for the loss of hearing. Since that time I have succeeded in bringing up his hearing distance on the non-operated side to voice at two meters.

In regard to the probable lesion after the operation I would suggest a hæmorrhage in the labyrinth happening during the anæsthesia or during the excessive vomiting thereafter, with subsequent organization of the blood clot. In respect to the advisability of the operation in this particular case, I would state that hereafter I shall not operate upon patients of his age. In a private communication from Colles,[8] of New York, over this case, he raised this objection and wrote that he did not think that the labyrinth was primarily involved and thought that improvement could be expected after cessation of the suppuration. Subsequent observation has not upheld this opinion. Dr. Colles considered sclerosis an unfavorable symptom. Stacke,[16] of Erfurth, also holds this view. On the other hand Sexton,[14] Burnett[6] and Schwartze[12] consider that the advance of progressive sclerosis may be effectually stopped by the procedure. My experience tends to substantiate the latter statement. Randall[10] and Seiss[13] do not consider the operation advisable in chronic aural catarrh.

One lesson from this case is that our prognosis as to the results of excision of the drum-head and malleus must be guarded and the patient must not have rose colored anticipations of the probable amount of benefit to be derived from the operation.

Discussion.

Dr. Randall said that the excision was done for two conditions so unrelated, that the suppurative and non-suppurative cases should be decidedly separated in discussion. His experiences in catarrhal cases had not been satisfactory—one of his cases, with no gain in hearing, having gone on to severe suppuration with mastoid empyema, burrowing to the neck and occiput, and life was saved by a hair's breadth. Gelle's test for stapes ankylosis often seemed the criterion in deciding between excision and stapes mobilization. In suppurative cases he was slow to operate, since most of the forty instances of attic disease with Shrapnell perforation, often with superficial cases seen in the last year, as in previous experiences, had improved so rapidly as to admit no question of operation. Done only in the most urgent and severe cases, the excision of the carious ossicles had proved disappointing. No instance of harm had occurred; nor a single brilliant result; the drainage had often not been specially improved as evidenced by the formation of new sinuses. In every case in which he had excised for caries, he regretted that he not done the more radical operation of Stacke, removing, as Walb puts it, the *bony* as well as the membranous outer wall of the tympanum. Thus only can the attic-caries be freely exposed to operative or other treatment. As to the operation in both forms of cases, the German experience was certainly much longer and larger than any on this side of the Atlantic, since Voltolini, Lucae, Hessler and Schwartze had each, probably, double the number of operations of Sexton or any other American.

Macluen Smith, Philadelphia:—Age has not in my hands had any influence in the result of the operation, and yet we must certainly expect better results from the more recent cases.

The youngest case was a child six years of age suppurative in character. The eldest was a gentleman of seventy-two years (non-suppurative) with distressing "menieres symptoms" for twenty-six years. This case was not for sixteen years, able to leave his chair or bed without the assistance of an attendant. This case was operated on left ear three years since, which markedly reduced his symptoms; the right ear was operated on one year ago since which time the patient is entirely relieved of vertigo and tinnitus, with sufficient restoration of hearing to enable him to appreciate most ordinary conversation, with continued improvement of hearing. We must, of course, look for and expect better results from the suppurative cases and I would consider it the surgeon's duty to give his patient the benefit of such surgical procedure, and thus reduce to a minimum the danger of mastoid and cerebral complications by allowing such pathological conditions to continue.

Dr. Richardson stated as this appeared to be an experience meeting he thought it wise for each to give his personal results. He had operated several times in these cases, but most of his work, like that of others present, had been for chronic suppurative cases, rather than the chronic catarrhal. In all he had done ten operations, eight for suppurative and two for non-suppurative catarrh. His six cases have already been reported, the other four are of too recent date to give results. An analysis of cases followed. In concluding he stated that he thought in many cases of disease of the attic, with involvement of the osseous wall and probable implication of the mastoid antrum he would prefer Stacke's operation to the present operation.

Dr. Seiss has not operated in catarrhal cases, and would not at present feel justified in doing so. In suppurative cases regard the operation as a distinct addition to aural surgery. Depends mainly upon mobilization of the ossicles to relieve hopeless sclerotic deafness—a long incision being made posterior to the malleus and traction made on the incudo-stapedial joint. Otherwise, incurable tinnitus may be almost invariably relieved by the speaker's method of freezing the mastoid. Ether, ethyolene, or chloride of ethyl may be used, are free from injurious results, and are most satisfactory in many cases, acting as a cure in a few cases.

Dr. Seth S. Bishop, of Chicago, said:—I have never hesitated to remove the drum head and ossicles when it was necessary to cure suppurative inflammation. But in the class of cases mentioned by Drs. Burnett and Würdemann, my opinion as to our duty is not so clearly defined. I have been loth to operate for several reasons.

In order to collect statistical information on the subject, a year or two ago, through the medium of the medical journals, I invited all American aurists who had performed this operation to communicate to me the outcome of their experience. Such a small number responded, and the results given were so unsatisfactory, that I was forced to the conclusion that either very few had operated, or the results were not of a nature to encourage the operators to report them.

I have opened the drum several hundred times. A number of years ago I reported the results of 30 cases I had operated upon. I had removed either the whole of the drum head or parts of it for the relief of tinnitis aurium and chronic progressive deafness attributable to non-suppurative inflammation. Many cases are benefited to a very satisfactory degree. I met one of those referred to a few days since, an operator on the board of trade, who says now that the operation was a benefit to him.

In another case in which I removed both drum heads, one remained well open, after a partial regeneration of the membrane, for a year and a half with satisfactory results as long as the patient remained under observation. After removing the other drum head there was a slight muco-purulent discharge. While this continued the hearing was much improved. After this discharge ceased the hearing distance diminished. The patient insisted that if the middle ear was kept moist he would hear better. I filled the ear with simple vaseline, and at the expiration of a week the drum head was found reproduced. Other cases were only slightly benefited, and some not at all.

Now it is a reasonable inference that if this opening of the drum head benefits a patient, a complete and permanent removal of it will make the improvement permanent. If the mallet is not removed the drum head will probably be reproduced, and it may be even after the ossicles are extractep. I would suggest the minor operation of removing a section of the membrane as a preliminary test. If this is followed by considerable improvement, then I would resort to the more radical operation. This much can be said in favor of the test operation: the removal of a section of the drum head is not followed by any disastrous consequences.

These observations are all based upon the supposition that the labyrinth is not involved in the disease. Should there be sclerosis, atrophy or paralysis of the auditory nerve, of course an operation to improve hearing is out of the question. But if the only trouble is that sound waves cannot reach the round window and foot plate of the stirrup because of the barrier interposed by the immovable ossicles and membrane, then an operation is a logical and promising procedure.

The case of failure reported by honest Dr. Würdemann, and for which report we owe him our acknowledgements, I have seen several times through his courtesy. A few weeks ago as this case was passing through Chicago, I made an examination and found that the right ear which had been nearly useless to him for many years, had been improving until he could hear loud conversation without the conversation tube. This ear had been treated but not operated upon. The operated ear remained useless for conversation, but he could hear me whistle all the tones except two of the scale from middle C upward one octave, through the tube. He could also repeat after me nearly all of the vowel sounds. The discharge had nearly ceased.

I may add, however, that nearly a duplicate of this case has recently come under my observation. Before the operation the patient said he heard his watch 2½ inches. A New York aurist removed the drum head, mallet and part of the anvil. The tinnitis was not relieved. He is totally deaf and has a purulent discharge from the ear.

Such cases are discouraging. In my opinion we should perform this operation only in such cases as I have described, after a preliminary test opening of the drum head, and giving the patient the benefit of any reasonable doubt.

Dr. Burnett said:—An accident following incision of the membrana and the auditory ossicula, was largely, if not entirely due to rough manipulation. Disturbances in taste after the operation is evanescent. When it has been disturbed in chronic suppuration before the operation, the sense of taste has improved after the operation.

Gelle's test for ankylosis of the stapes is not necessary in chronic catarrh if any hearing is present, as hearing would prove that the stapes is not entirely ankylosed. Even if ankylosis of stapes were to exist, this should not prohibit the operation of excision in aural vertigo and severe tinnitus. Stacke's operation, or Arbuthnot Lane's operation is a mastoid operation and not to be compared with excision of the membrana and ossicles in attic suppuration. If excision is performed promptly in attic suppuration there would be much less need for mastoid operations.

Dr. Würdemann, of Milwaukee, in closing the discussion:—Young men, as a rule, are apt to take up these new operations which are so highly advocated. I presume that I am no exception to the rule, but in regard to these chronic suppurative cases with necrosis of the ossicles coming to me (generally they are "rounders") I am disposed, after cleansing and antiseptic treatment has been tried, to urge an operation. Gentlemen, I get tired of treating these cases after a few weeks. In chronic aural catarrh I believe we should be conservative and choose our cases. My experience in non-suppurative disease is limited to four cases. In one total deafness followed the operation, as reported in this paper. In the second, a negative result; in the third, the tinnitus and deafness were markedly relieved, and in the fourth the results are not yet fully developed. In this last case I have been obliged to do two secondary operations on account of regeneration of the drum-head again diminishing the hearing.

SPASTIC CONTRACTION OF TENSOR TYMPANI MUSCLE.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY C. W. RICHARDSON, M.D.,
Professor of Laryngology and Otology, Medical Department Columbian University, Washington, D. C.

The purpose of this paper is to present, in as concise a manner as possible, a case of objective noise in the head. Objective noises in the ears are of uncommon occurrence, as only a small number of cases have been reported. The sound usually produced is said to resemble the snapping of the finger nails, or the sudden drawing apart of the finger ends when slightly moistened with saliva or a tenacious fluid (Burnett).

The case which I present was under observation many months, during which time it was the subject of considerable study, and of curiosity, to many of my colleagues.

Belton Adair, a young half-breed Chinese boy, 16 years of age, was referred to me by Dr. H. A. Robbins. His parentage is interesting. The father was one of the first Chinamen ever brought to the Atlantic Coast. He came over with Admiral Perry, and was said to have been quite a botanist. Settling in the South, he made the acquaintance of a poorly educated German woman whom he afterwards married, and who became the mother of three of his children, the subject of the present paper being the eldest. The father died young and his medical history is unknown. The mother is excessively deaf, communication with her being almost impossible. The boy is said to have possessed the usual physical development and activity of the average American youth of his age, until about his fourteenth year. Mentally he was said to be very precocious. He passed through the ordinary diseases of childhood, from which he made good and complete recoveries. At this period it was noticed that he had a peculiarity in walking, a slight uncertainty, but as this was considered to be a racial peculiarity not much attention was given it. During the spring of his fourteenth year the aural trouble, which makes him the subject of the present paper, developed. His guardian attributes his affliction to the habit the American children had of stuffing his ears with snow. The first phenomenon noticed was an intermitting roar which, after several months' duration, was followed by the "ticking," which continued without abatement until he fell under my observation. This noise was not only subjective, but was distinctly audible to one when coming in close contact with the patient's head. His guardian told me that her attention was first attracted to this unusual noise on a certain Sunday while at prayers in church, when the boy's head was resting against her own. During the prayers she heard the ticking, and supposing it to be a watch which the boy must have secreted, she demanded of him where he had obtained it, when he replied that it was that awful noise in his head. The ticking existed in both ears, but was always more persistent, continuous and irregular in the right than in the left ear. It was never absent in both ears simultaneously. It would frequently subside in one or the other ear for a few moments, hours or days; but never in both ears at the same interval. There was a want in rhythm in the same ear at all times, and absolutely none between the two ears. The right ear was far more regular in its click, if I might so call it, and I have noticed frequently that at different visits and at different intervals on the same day it would register the same number of beats to the minute. The left ear was markedly irregular—it might register one beat in one minute, thirty at the next, five during the third minute, and during the fourth remain absolutely quiet. Applying an otoscope to each ear of the patient connected with each ear of the observer, the following points were observed: The clicking in each ear was entirely independent of the other, they seldom or never pulsated synchronously, the clicking in the right ear was always more rapid and therefore more to the minute than that in the left ear, and lastly, it was noticed that they were not synchronous with the heart's action. The sound heard through the otoscope was the characteristic muscular click which attends the contraction of all muscles when in motion. This sound can be heard by the application of a stethoscope to any muscle while it is brought into active contraction, well heard over the masseter. I never heard the sound unaided by the otoscope. I never brought my head in close enough contact with that of the patient. Perhaps I was a little more scrupulous than scientific. I have no reason to doubt the observations of others on this point, as the first motion the poor sufferer made on being brought to me was the bending of his head forward in order that I might hear the sound within his head. At the time he fell under my observation, July, 1888, in his sixteenth year, he was evidently a great sufferer. The sounds in his head had existed for nearly two years without interruption. He was deprived of sleep and was almost unable to carry on a continued train of thought, on account of the distraction due to the incessant ticking. Lately, his guardian tells me, he had given up his books, as he found it impossible to study. For several years past he would frequently be noticed striking his head with his closed fists or against surrounding objects, so as to cause a cessation of the noise. Since this affection of his auditory apparatus he had lost a great deal of his brightness, mental vigor and clearness of intellect. His physical condition was not as satisfactory as it had been six years ago. He was of the average height, with a Mongolian cast of features, body well nourished, limbs very thin. In walking there was a marked unsteadiness of gait, a want of coördination, and a tendency to fall "all in a heap" in coming in contact with even slight obstacles. There was a certain amount of "lallying" in speaking and his ideas were very crude, causing one to doubt of his ever having showed any particular brilliancy of intellect. Memory was said to be fairly good.

Examination of Ears.—In this description, as both ears presented practically the same changes, it will not be necessary to designate right and left.

Auditory canal large, roomy and nearly straight, so that membrane could be readily viewed without aid of speculum.

Membranes normal in color, but dull; no opacities, cicatrices, atrophic spots or deposits. No light reflex, marked contraction, so that manubrium was directed almost vertically inwards, the umbo resting upon promontory. Short process very prominent. Siegle's otoscope demonstrated normal mobility of anterior and posterior segments of membrane; the manubrium remaining motionless. Careful ocular inspection, made many times and for prolonged periods, while sound was very distressing to patient, failed even to reveal the slightest movement in the m. t. or parts thereof. Eustachian tubes slightly contracted. On inflation air entered cavities freely, but with slight increase in pitch of sound. During inflation the anterior and posterior segments of membrane would bulge out, though manubrium would seem to be motionless. If manubrium showed any movement it was so slight as hardly to be noticed. The membrane would almost immediately assume its usual position after inflation, the injection along manubrium and upper pole being the only evidence of an inflation having been made.

The patient was to a certain degree unreliable in the testing of the hearing, but from frequent examination and under varying surroundings, I concluded that hearing was practically normal for the acumeter, loud and whispered voice. Bone conduction normal.

Nasal and pharyngeal cavities were normal. There was no catarrhal inflammation of these cavities, nor was there any evidence of there ever having been any. Supposing that these muscular sounds might possibly be due to movements of the palati or constrictor muscles, I made frequent and prolonged examination of the oral and nasal pharynx without ever having observed the slightest quiver or twitch in these muscles; although through the intervention of the otoscope there was an incessant tapping going on in patient's ear. He became so skilled in rhinoscopic examination that he would allow the mirror to remain within the pharynx for many minutes without contracting soft palate or showing other evidence of tiring. It was also observed that neither of the processes of deglutition or phonation had the slightest influence on the frequency or rhythm of the muscular click. It was interesting to observe the influence exerted over the ticking,by the use of inflation through the medium of the catheter. The catheter being introduced, connection having been made with the patient's ear through the medium of the otoscope, the ticking progressing as usual, several inflations were then made, when it was noted that there was a momentary cessation of the clicking, followed by several short, sharp clicks and then a pause. This pause was only for a few moments, when the ticking would again return with its original intensity, unless the inflations were persisted in. After each inflation the reaction became weaker and the pauses greater, so that after several energetic efforts the silence became assured for several minutes or hours. Allowing the catheter to remain in the mouth of tube, without resorting to inflation, had no influence over sounds. During a prolonged course of treatment the ears progressively but slowly improved, under this form of inflation, until the clicking entirely subsided.

The muscular clicking having ceased after being under my care for a period of about six months, the patient passed from under my observation.

The subsequent history of patient under the care of Dr. H. A. Robbins, was that of a slowly progressing case of pachymeningitis.

The patient died February 21, 1891. The autopsy was made by Dr. I. W. Blackburn, pathologist to the United States Government Insane Asylum, in the presence of Drs. R. T. Edes and H. A. Robbins. Dr. Edes took notes. Unfortunately, I was not aware of the boy's death until some weeks after the occurrence

Autopsy.—Belton Adair, æt. 18, ten hours after death. Sutures visible externally as well as internally. Skull separated at apex of lambdoidal suture. Skull cap rather thicker than normal; although possibly softer than normal. Dura not unusually adherent. Slight delicate, filmy membrane adherent to dura along vertex on right side. Nearly the whole of the vertex of the inner surface, on left side, was covered by a thick, bulky false membrane, thicker in the center, thinning out toward the periphery, occasioned by a hæmorrhagic effusion. This membrane could be separated with considerable ease from the dura. Extreme œdema and opacity of pia. Convolutions shrunken over anterior and superior regions. Pia firmly adherent to cortex, separation only being attended with tearing away of cortical substance—this throughout. Difficult to say whether fluid was in subdural space or in subarachnoid—probably latter. Convolutions hard, with shrinkage more marked over superior portions. Ventricles contained a little more fluid than normal. Lining of fourth ventricle granular. Cribriform appearance very marked above anterior perforated space.

The most important point in connection with a case of clonic muscular ticking heard within the ear is to locate the particular muscle or group of muscles which is occasioning the peculiar sound heard. Few cases of this character fall under the observation of any individual observer, and therefore it is impossible almost to lay down differential points. We can only, reasoning from physiological functions, surmise what would take place in case of involvement of one muscle and what would occur were another affected. In this case the possibility of the involvement of other muscles than the muscles of the middle ear can be excluded, and for the following reason, viz.: the sound produced was clear and sharp, entirely different from that heard during the involuntary contraction of the constrictor or palati muscles. In case of palati and constrictor contractions there is visible movement in soft palate and pharynx. There was none noticed here. In contraction of pharyngeal muscles the patient is as much annoyed by the muscular twitching in the throat as by the noise in ears. The patient never once referred to any sensation in pharynx of this character. Deglutition would necessarily influence sounds were the pharyngeal group of muscles at fault.

Examination of patient some three months after cessation of spasm of muscles revealed the membranes less rigidly contracted, and the manubrium responding slightly to the use of Siegle's otoscope. The action of inflation would seem also to establish the implication of this muscle. The cessation of the clicking after many forced inflations, evidently due to the over-stretching of the tensor tendon, which would become for the time being unresponsive to centric irritation. The absence of visible movement in membrane proves nothing, as the vibrations produced by contractions of this muscle would be so slight as to be hardly recognized by the unaided eye. Monometric study would have been of value here, and its want of use was an act of negligence on my part. I had thought of dividing the tendon of these muscles, and tried to gain the consent of guardian, but it was of no avail. Had either of these observations been carried out the history of the case would have been complete.

The pathology of the spastic contraction in the present case seems to be one of centric origin, the lesion being probably at the seat of origin of the nerve supplying the tensor, or lesions involving the nerve in its passage through the cranial cavity. Individual nerves supplying individual muscles, nerves supplying groups of muscles, nerves of general sensation and nerves of special sense, were involved at progressive stages in the life history of this case, until the individual, shortly before death, became a motionless, sensationless and senseless mass of humanity. The cause of the contraction in the tensor, as in several other groups of muscles, must have been due to primary centric irritation. The cessation of ticking was more due to the destruction of the function of the nerve than to the treatment instituted by me.

1102 L St., Washington, D. C.

Discussion.

Dr. Randall said that he was able to cause voluntarily such a clicking sound in the ears, synchronous with palatal contractions, yet not wholly caused by them, since at times unilateral and independent. The sound is audible to outsiders, and seems to consist of a fine dry click as well as the moist separation of the Eustachian walls.

Dr. Lewis H. Taylor, Wilkes Barre, Pa.: I have notes of a similar case which I have always intended publishing, but as yet have never done so. The patient was a young woman of 25, in fairly good health, who came to me about three years ago on account of excessively annoying sounds in her ear, which were subjective and objective as well.

By placing my ear near hers, say 2 inches away, the sounds were distinctly audible, while with the tube in her ear and mine they were quite loud. They were of the nature of a constant ticking, regular and unvarying. She came for treatment, which I am sorry to say did no good, and I soon lost sight of the patient.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(*Continued from page 472.*)

Case 6.—Treated by Frank Allport, of Minneapolis, Minn. C. B., Male, age thirty-five. Entered City Hospital December 7, 1888. I saw the case December 10, at the request of Prof. Dunn.

At the date of his admission he was obviously very sick and his mental condition was such as to render a thorough knowledge of his previous condition impossible. We learned, however, that his left ear had discharged for about three months, accompanied by severe head pains. He has had a diarrhœa and chills; his tongue was dry and coated; he was delirious, and had aphasia and incoherent speech; no paralysis; the auditory canal was full of pus; there were no mastoid symptoms; there was a swelling just under the mastoid process in the neck, about the size of a hen's egg, that was somewhat tender, but not fluctuating; the surface of his body was very hot and dry; his temperature varied from 102½ to 103½, and his pulse was from 104 to 120. He died December 11.

Autopsy by Professors Dunn, Jones and myself. The large vessels of the dura and pia-mater were filled with dark blood; the inferior surface of the cerebellum is softened, discolored and purulent; the basilar artery and circle of Willis are filled with dark venous blood; the middle and internal ear contained foul thick pus; there is a purulent thrombus in the left petrosal sinus, both superior and inferior; there is a purulent thrombus in the lateral sinus and in the internal jugular vein; the external jugular vein for some distance down the neck shows evidences of purulent phlebitis; the vein from the auditory canal is in the same condition; pus is found in the semi-circular canals; there is a thrombus in the basilar vein; the superficial posterior auricular glands were found to be much enlarged; there was no pus in the mastoid cells.

Case 7.—Archives of Otology, 1885. Treated by A. Hedinger, of Stuttgart. Female, age sixty-three. Right ear. Came to Hedinger in 1874, with a history of chronic otorrhœa. Fibrous tumor in meatus; numbness right side of neck and face; patient disappeared for years; came again in 1883; severe pain in ear; aural hæmorrhages intermixed with pus; totally deaf in right ear; fibrous tumor still present; pain in back of head and temporal region; swelling of temporal region; moderate fever.

April 23. Temporal swelling incised and pus liberated; improvement. May 17. Incision in the cheek is made and pus liberated. June 19. Another incision over mastoid muscle and pus liberated. Oct. 30. Painful swelling over posterior part of mastoid process. Mastoid opened and pus liberated. Nov. 8. Delirium; right pupil contracted. Nov. 12. Stupor. Nov. 15. Total unconsciousness; spasms of left upper and lower extremities; left facial paresis. Nov. 17. Death.

Autopsy.—Multiple pus sinuses in the neck; carious spots on outside of mastoid and occipital bones; congestion of dura-mater and pia-mater; the right sigmoid sinus, bulbous portion of jugular vein, and the mastoid emissory vein, all obliterated; tumor in middle ear; malleus and incus gone; pus in mastoid antrum; a carious canal leads from the mastoid antrum into a cavity in the sigmoid fossa; carious opening through the incisura santorini; caries of the pyramid; caries of the bony wall of transverse sinus.

Case 8.—Archives of Otology, 1885. Treated by A. Hedinger, of Stuttgart. Female, age fifty. Chronic otorrhœa, both ears. Vertigo, violent pain in the head, especially in occipital region. Temperature and pulse subnormal. Right ear contains polypus: removed. Left ear, chronic otorrhœa, simple. Received conservative treatment from Hedinger. Treatment unavailing; coma; death.

Autopsy.—Intense hyperæmia of all meningeal veins. In the center of the superior petrosal sinus is a small carious opening directly over the vestibule. Petrous bone carious. Pus in middle cranial fossa running into the canal of the medulla oblongata. Abscess in left posterior cranial fossa where cerebellum rests. Cholesteatoma in left mastoid antrum. Caries of semi-circular canal, vestibule and cochlea.

Case 9.—Archives of Otology, June, 1886. Treated by A. Truckenbrod. Male, age twenty-eight. Left ear, chronic otorrhœa. Has suffered from attacks of vertigo; has now chills; very painful spot on top of head; meatus narrowed; headaches; temperature rises moderately. Mastoid opened; found pus; improvement for a few days. Temperature rises again; pain in top of head and temple; paresis of right side of face; difficult speech; defective memory; aphasia. Diagnosis. Brain abscess.

Operation.—Fistula found in squamous bone directly above the meatus, which was enlarged. Search made for pus, which was found. Irrigation with sublimate solution 1–1,000. Sublimate gauze dressing; drainage tube; recovery.

The abscess was in the second left temporal convolution. The diagnosis was based on, 1. Oedema of this region; 2. Pain in this region; 3. Paralysis of right facial nerve.

Case 10.—Lancet, 1885, Vol. 2, page 665. Left ear. Treated by Hide Hilles. Chronic otorrhœa. Death.

Autopsy.—Cerebral meningitis. Abscess of left temporal lobe.

Case 11.—Lancet, May 15, 1880. Treated by James Allen. Female, age nineteen; right ear; chronic otorrhœa; deafness. Dec. 18, 1879. Ear-ache; entire head painful; vomiting; paraplegic; motor paralysis of lower limbs; scalp and spine very painful to touch. Death.

Autopsy.—Abscess beneath dura-mater on anterior surface of right petrous bone. Drum-head and ossicles destroyed. Pus in middle ear, mastoid cells, and labyrinth. Vertebræ in portions of cervical and dorsal spine carious. Pia-mater congested.

Case 12.—Gazette des Hopit., No. 67, 1880. Treated by C. Miot, Paris. Male, age thirty-five. Tubercular. Chronic otorrhœa. Right facial paralysis. Painful mastoid. Death.

Autopsy.—Pus in middle ear and mastoid cells; ossicles gone; caries of tympanic walls; dura-mater red, thickened and softened. Facial nerve and chorda-tympani largely destroyed.

Case 13.—Journal of Anatomy and Physiology, Vol.

[illegible]

XIV. Treated by P. McBride and Alex. Bruce. Right ear. Chronic otorrhœa. Death.

Autopsy.—Pus in middle ear, mastoid cells, vestibule and cochlea. Abscess in outer half of right cerebral hemisphere, adherent to the posterior surface of the petrous bone, in the vicinity of the internal auditory nerve. Dura-mater detached at this point.

Case 14.—Archives of Otology, July, 1879. Treated by C. J. Kipp. Male, age twenty-three. Right ear; chronic otorrhœa. Acute exacerbation. Pain over right side of head. No mastoid tenderness. Meatus red; chills; fever; vomiting; headache; both optic nerves congested; convulsions; unconsciousness; bowels regular; coma; death.

Autopsy.—Longitudinal sinus filled with blood. Abscess in temporal lobe; not encapsulated; on removing the lateral sinus, puriform fluid escaped, which was found to come out of a round opening in the anterior and outer wall of the sinus. A large thrombus existed in the sinus. Pus in middle ear and mastoid cells. Drum-head perforated. Malleus and incus carious.

Case 15.—American Otological Society, July 25, 1882. Treated by A. Mathewson, of Brooklyn. Male, eleven years; chronic otorrhœa; mastoiditis; apparently cured; recurrence; convulsions. Death.

Autopsy.—Abscess of cerebellum. Pus between dura-mater and tegmen-tympani.

Case 16.—American Otological Society, July 25, 1882. Treated by C. S. Merrill, of Albany. Male, age 32; acute otitis. Death.

Autopsy.—Pus over the region of the petrous bone, extending from the tympanic cavity through two or three small openings in the tegmen-tympani.

Case 17.—American Journal of Medical Sciences, May, 1892. Treated by G. W. Prentiss. Male, age 31. Right ear; chronic otorrhœa: earache and headache; chills; fever; high temperature; pain in the temporal region and over right eye; mastoid unaffected. Death.

Autopsy.—Abscess in anterior lobe of left hemisphere of cerebellum. Marked discoloration of the dura-mater covering the petrous portion of the temporal bone. Caries of petrous bone at this point. Lateral sinus filled with clotted blood. Purulent opening through the walls of lateral sinus communicated with the abscess.

Case 18.—American Journal of Otology, July, 1882. Treated by Mr. Field, of England. Male, age 42. Chronic otorrhœa; left ear. Death.

Autopsy.—Congestion of dura-mater. Puro-lymph in meshes of pia-mater over the left sphenoidal lobe. Abscess in left lobe of the cerebellum. The temporal bone was considerably necrosed with yellowish and greenish discolorations on the walls of the tympanum. Middle ear full of pus. Drum-head gone.

Case 19.—Philadelphia Medical Times, August 27, 1891. Treated by G. C. Harlan. Female, age 14. Left ear; chronic otorrhœa; left facial paralysis. Death.

Autopsy.—Meningitis. Abscess of the left lobe of the cerebellum. Almost entire destruction of the anterior wall of the ex. meatus. Drum-head gone. Caries of middle ear.

Case 20.—Edinburg Medical Journal, June 1881. Treated by Robert Sinclair. Male, age 22; right ear; Chronic otorrhœa; took cold; unconscious; maniacal; right pupil contracted; mastoid swelling. Wildes' incision. No relief. Death.

Autopsy.—Abscess having a direct communication with the middle ear, in tempero-sphenoidal lobe.

Case 21.—Australian Medical Journal, April 15, 1881. Treated by Robertson. Male, age 39; left ear; total deafness; no previous history; purulent discharge from ear; left facial paralysis. Death.

Autopsy.—Caries in middle ear. Abscess in left middle crus-cerebelli, extending partly into the cerebellum itself, and inwards into the pons abutting on the fourth ventricle and pressing on the seventh nerve.

Case 22.—New York Medical and Surgical Brief, February, 1879. Treated by W. Oliver Moore. Male, age 50. Right ear; chronic otorrhœa; acute exacerbation; swollen mastoid; abscess opened; vomiting; semi-consciousness and facial paralysis; divergent strabismus. Pupils contracted. Death.

Autopsy.—Caries extending backward and upward from the mastoid portion as far as the parieto-occipital suture. There was an opening through this suture leading into cavity of the skull on a level with the lateral sinus. The sinus was empty and felt like a fibrous cord. A probe passed through it was arrested just where the lateral sinus joins the jugular vein. Meninges very much congested. Pus in the posterior fossa between dura-mater and skull. Caries at this point. Abscess in right lobe of cerebellum.

Case 23.—Glasgow Medical and Surgical Journal, January, 1880. Treated by Thomas Barr. Male, age 17; left ear; chronic otorrhœa; pain, especially in left side of forehead; lanquid and drowsy; vomiting; aphasia; epilepsy.

Autopsy.—The left sphenoidal lobe was found adherent to the bone beneath. Abscess in left sphenoidal lobe. Petrous bone carious in two places. One through roof of the tympanum; the other in the groove for the lateral sinus. The last one communicated with the mastoid cells.

Case 24.—Journal of Anatomy and Physiology, April, 1888. Treated by P. McBride and Alexander Bruce. Female; chronic otorrhœa; death.

Autopsy.—Abscess in cerebellum, right lobe.

Case 25.—Gazette Hopitaux, No. 39, 1885. Treated by Jaccoud. Right ear; tubercular case; sudden pain and deafness; profuse discharge; vomiting and dizziness; mastoid painful; fever; death.

Autopsy.—Pus at base of middle lobe of cerebrum. Tympanic cavity purulent, granular and carious. Drum-head destroyed.

Case 26.—Von Langenbeck's Archives, Vol. 28, page 556. Treated by T. H. Gluck. Right ear; chronic otorrhœa; aural hæmorrhages; headache; fainting; convulsions; amaurosis; soporous condition; facial paralysis; paralysis of right arm.

Operation.—Posterior wall of meatus chiselled away, also a portion of the mastoid. The dura-mater was exposed, and appeared fluctuating. Pus found between dura and pia-maters. Death.

Autopsy.—Purulent degeneration of the dura mater, especially from the longitudinal sinus to the base of the brain.

(*To be continued*)

THIOCAMF presents a ready way of using sulphur dioxide as a disinfectant. He says a combination of camphor and sulphurous acid presents the germ-destroying agent in a very concentrated and convenient form.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.
SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES . . . . 10 CENTS.
Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
No. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1271, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 22, 1892.

AMŒBIC DYSENTERY.

The clinical term dysentery includes various forms of intestinal flux due to inflammation and usually ulceration of the large intestine. While the primary etiological agents in the acute catarrhal and the diphtheritic forms of dysentery are as yet but imperfectly understood. The so-called tropical variety of dysentery has been made the subject of investigations that show it to be a distinct disease from an etiological, a clinical, as well as an anatomical standpoint. The investigations of LOSCH in Russia, of KARTULIS in Egypt, of COUNCILMAN and LAFLEUR as well as others in this country and elsewhere, show the amœba coli (LOSCH) of dysenteræ (COUNCILMAN and LAFLEUR) to be constantly present in the evacuations and in the intestinal lesions of tropical dysentery as well as in the quite frequent secondary liver abscesses and in the sputum after the rupture of such purulent collections into the lung. KARTULIS and HLAVA have made successful injections into the large intestine of cats and dogs with pure amœbic cultures on straw infusion or with dysenteric stools. The amœba is a unicellar, neucleated, proto-plasmic and vacuolated organism, capable of amœboid movements, showing usually a clear outer zone or ectosare and a granular and vacuolated inner zone or endosare; it varies in diameter from 10-30 or more micro-millimeters, and is very easily demonstrated in the warm stools of tropical or amœbic dysentery the diagnosis of which practically rests upon the detection of the amœba in the discharges. The excellent clinical and anatomical studies of COUNCILMAN and LAFLEUR (*Johns Hopkins Hospital Reports*, vol. ii, 1891), based upon a thorough review of the literature and the analysis of 15 cases of the disease occurring mostly in OSLER'S wards, showed that amœbic dysentery has a variable onset, course and duration with intermissions and exacerbations, tending always to chronicity and early anæmia; that abscess of the liver with or without lung involvement is a frequent complication; that anatomically the ulcers differ from those of other forms of dysentery, being produced by a primary submucous infiltration and subsequent necrosis of the mucous membrane, and consequently they present very distinctly undermined edges; in these ulcers as well as in the liver abscesses purulent inflammation is absent unless a secondary infection with bacteria should occur. As is well known, tropical dysentery is very common in tropical and subtropical countries where it frequently occurs in epidemics, but it also appears throughout Europe and North America. MUSSER has demonstrated the disease in Philadelphia and HEKTOEN not long ago exhibited before the Chicago Medical Society specimens of the intestine with microscopical preparations, from a typical case occurring in a young man who died in Chicago, after having contracted the disease in Galveston, Texas. Comparison of the specimens of dysenteric intestine in the Army Medical Museum at Washington, gathered during the War of the Rebellion by the industrious and able WOODWARD, with the intestine of the amœbic dysentery of to-day show the lesions to be in many instances exactly alike. The natural habitat of the amœba dysenteræ has not yet been found, but it is thought that drinking water is one of the sources of infection.

SUTURE OF THE SPINAL CORD.

In an able paper read before the American Surgical Association in 1891, PROFESSOR J. WILLIAM WHITE reviewed the subject of the surgery of the spine, and made a very complete survey of the reported cases of operative measures employed to relieve the consequences of spinal traumatism. Of the thirty-six cases of laminectomy performed in the post-antiseptic period, fourteen, or thirty-nine per cent., died; but he concluded that the results in general were encouraging for the advantage of surgical interference, except in those cases in which there was disorganization of the cord.

Of course, in all cases of spinal traumatism, more or less injury to the cord ensues; and the influence of operative interference on the degenerative process in those cases in which there is no injury to the vertebræ, is a matter of great surgical importance, including as it does, the questions of early or late operations, and of a more important factor, the desirability of operating on the cord itself.

In 1852 PROFESSOR BROWN-SEQUARD published the results of his experiments, showing that a more or less complete regeneration of the continuity of the various tracts in the spinal cord followed hemisection of the cord at various levels. The cords removed from the animals experimented upon, were examined by FOLLIN, LEBERT, LABOULBENE and

Robin, who found reunion of the severed portions with a new production of cells and fibres. In the past year similar experiments were performed by Fr. Sgobbo, who was unable to obtain regeneration of the cord in any subject of his experiments except the triton; he used also, lizards, tadpoles, frogs, pigeons and dogs. Histological examination showed, however, in all of the animals examined, that notwithstanding the degenerative processes in the gray and white substances of the cord the epithelial cells of the central canal remained intact or were in a fair condition for regeneration. The embryonic origin of the cord being from this epithelium, and the new cord in the triton arising from it also, we must look for some intrinsic cause for the failure of the nervous elements to proliferate and unite. Pathologically this cause seems to be the rapid formation of connective tissue and its interposition between the severed ends.

Such a result often follows traumatic section of a nerve; and exsection of the fibrous band with coaptation of the freshened ends has resulted in restoration of the integrity of the nerve.

This has probably induced surgeons to ask themselves if the same result could not be accomplished in cases of old injury to the spinal cord. Dr. R. T. Morris published in 1886 the history of a case of traumatic paraplegia, on which he operated in 1885 with the intention of excising the damaged portion of the cord and suturing the ends together. On exposing the cord he found the injured tract so extensive that exsection was out of the question.

Chipault has recently brought this matter forward again, in an interesting paper on the surgery of the spinal cord in the *Revue de Chirurgie* for August. He considers such an operation to be impossible anatomically. He states that in the cadavers of three persons who had vertebral fracture, in two of which there was complete section of the cord, the retraction of the medullary segments and the extent of the sclerosis necessitated a resection of several centimeters; and the loss of elasticity of the cord as well as the resistance of the ligaments formed by the pia mater, prevented the apposition of the resected ends. If the cord has been simply divided by a cutting instrument it may be sutured in the cadaver, and without doubt in the living subject, by fine silk sutures passed through the pia mater.

It is possible that some of the questions involved in suturing the spinal cord may be determined by experiments upon animals. But Morris's experience in finding an extensively degenerated tract that precludes exsection, would probably be paralleled by most surgeons operating on old spinal injuries with a similar end in view. For various experimenters, in testing the elongation of the cord by suspension of the cadaver, found that the lengthening varied from eight to twelve millimeters (five to eight-sixteenths of an inch), while several centimeters may be diseased. So it would be manifestly impossible to co-aptate the ends after excision of so long a portion of the cord; nor would this probably be facilitated by the proposed excision of a vertebra. It is evidently better to operate early in such cases of spinal injury as indicate osseous or sanguineous pressure on the cord, thus lessening the risks of fibrous degeneration and consequently eliminating the question of excision and suture.

THE ENCOURAGEMENT OF HIGHER MEDICAL EDUCATION BY PHYSICIANS.

There is a sentiment among many physicians that a thorough preliminary education, equal to the bachelors' degree in science or arts, is unnecessary and even undesirable for the young medical student. Students are frequently advised by their preceptors to discontinue their literary and scientific education to begin the study of medicine in the office of the doctor. To such advice medical educators sometimes add the weight of their too eager opinion. But the unbiased and thoughtful educator will always encourage thorough literary training. The country is so much more prosperous that the number of college graduates has increased two hundred per cent. or more since the war, and there is reason to believe that our medical school can soon have a class, the majority of whose members have received liberal educations. Let no preceptor advise the young aspirant for a medical career to discontinue his college course short of its completion.

In another manner the preceptor is often a great sinner against the best interests of the student and the profession. He gives a certificate of study where there has been no study. Every preceptor's certificate should show the number of hours spent in recitations and quizzes, the subjects studied and the facilities for study. The writer deprecates the ruling of the Illinois State Board of Health allowing one year's study under a preceptor to count as one year of time on a four year course. If such study is of any value, its value is derived from the association with a high minded physician, from experience in the management of patients and patients' families, and from clinical study of suitable cases. All of these advantages are better secured during the long vacations or by study with a preceptor after the medical studies in the college are nearly finished. Now the preceptor's certificate is generally a fraud. It should never be given and should never be received. It needs no other evidence of its fraudulent character than the fact that students frequently possess themselves of two such certificates from two honorable physicians, covering the same time, and in one instance a student fortified himself with four, though he had all the time been engaged in an incompatible vocation.

The best service the practitioner and preceptor can do medical education to-day, is to encourage the highest standard of preliminary education, insist on the four years of attendance at the medical school, supplement the training of the medical school with adequate opportunity for obstetrical practice and practice in medicine, and surgical diagnosis, and instruction in medical ethics both by precept and example.

SKIN-GRAFTING FROM THE DOG.

At Bellevue Hospital, New York, the integument of a black and tan dog was used to repair an extensive injury to the scalp. The patient, a woman, sustained an accident in December, 1890, which has rendered necessary six grafting treatments. In the preceding operations, human grafts had been employed, the skin having been taken from the legs and arms of her husband and her friends. These have been only partially effective, an unhealed surface at the top and back of head nearly six by nine inches having resisted the former implantations. The most recent attempt was the use of a canine graft, a procedure that has seldom been used in this country, although it has in certain sections of Europe been quite frequently tried. In this Bellevue case, both the woman and the dog were anæsthetized, and the dog was killed after the removal of the graft.

AN ALLIANCE OF QUACKS

The bone-setters of France have formed a defensive alliance with the magnetic healers, mediums, *masseurs* and others of that class, their object being to organize a national league "to protect and advance their professional interests." In a recent manifesto complaint is made that there is a tendency towards an "undue and unauthorized legislative interference" and a claim is made that it is the inalienable right of all men to heal themselves, or get treatment wherever and from whomsoever they may elect. They therefore propose to make themselves felt in the elections; the specious cry of "fair play" will be put into active use early and late, and it will not be surprising to learn that they secure a semblance of legality.

Having been asked to undertake a research at the expense of the Government of his Highness, the Nyzam of Hyderabad, India, with the object, if possible, of reconciling the conflicting views concerning the action of chloroform, I am anxious to receive from American physicians and surgeons records of any cases where it was noticed that the heart stopped beating *before* respiration, or respiration stopped *before* the heart. Notes concerning any such cases will be considered strictly confidential, provided the reporter states his desire that his name shall not be mentioned in the report of the research when it is finished. Otherwise due credit will be given for any information received.

H. A. Hare,
Jefferson Medical College, Philadelphia.

Chamber of Commerce Cholera Report, New York.—We have received a copy of the report on cholera made by the Advisory Medical Council of the above named body. The report is signed by Drs. Stephen Smith, Chairman, Abram Jacobi, E. G. Janeway, T. M. Prudden, R. H. Derby, Hermann Biggs and Allen M. Hamilton. These gentlemen were selected to fill the honorary positions on this Council, by a special committee of the Chamber of Commerce, early in September, and their report was handed in on the 21st of that month.

The report is worthy of reproduction here in its entirety, but we propose now to quote only a paragraph relative to a short detention of persons at quarantine stations. The Council reports as follows: "We believe that under ordinary conditions the period of quarantine detention of healthy persons when removed, as they should be at once on their arrival in port, from all known or possible sources of infection, and properly placed, should be five days in case no cholera occurs among them." This paragraph, with others of a like tenor in the report, indicates that a more enlightened and humane spirit will in the future direct the form and duration of that imprisonment of innocent persons that is called "quarantine." Detention cannot be, and will not be, abandoned, but it will be planned and maintained with less of panic and heartlessness than has been the case in the past.

It is interesting to note that among the members forming this honorary Council there are several who only a short time before made their exit from the New York City Board of Health, because of the peculiar methods of the latter towards its medical officers. Not to name them all again we would say that we refer to Drs. Stephen Smith, Jacobi and Janeway. They were allowed to quit the Board with some sneering remarks about "having feathered their nests" and other similar reflections (see the letter published in this Journal, August 6). Only a few weeks roll away. and with cholera at our doors, we see the great Chamber at once calling to its aid these selfsame leaders and authorities in preventive medicine. And we see these representative medical men responding promptly and effectively, and thereby illustrating the time-honored adage, "*Miseris succurrere didici.*"

It may be expedient in a later issue to publish the entire report.

BOOK REVIEWS.

Atlas of Clinical Medicine. By Byron Bramwell, M.D., Assistant Physician to the Edinburgh Royal Infirmary, etc. Vol. ii. Part 1. Edinburgh: T. and A. Constable, University Press.

The first part of the second volume of this valuable work has just been issued. It maintains the high standard so characteristic of the excellent professional work that Dr. Bramwell is accustomed to do, and which is so familiar to the medical profession.

The subjects treated of in this number are: 1. Scrofula; 2. Unilateral hypertrophy of the skull; 3. Measles; 4. Two cases of Friedreich's ataxia, in which the knee-jerks are not lost. 5. Alterations in the fields of vision, their clinical significance and importance. Illustrative cases: Permanent hemianopsia due to a destructive lesion of the half-vision centre. Temporary hemianopsia due to an irritative lesion of the half-vision centre.

The plates are: Two ofscrofula; two of unilateral hypertrophy of the skull. Measles. Perimeter charts showing alterations in the fields, both for white and for colors, in cases of hemianopsia. Naked eye appearance of the brain in two cases of lesion of the half-vision centre. A series of transverse vertical sections through the brain in a case of lesion of the half-vision centre.

With this part are also issued: Perimeter charts, showing the fields, both for white and for colors, in cases of central amblyopia (? tobacco amblyopia) and lead poisoning. Secondary syphilis.

All of the illustrations are more than ordinarily well executed. It is to be desired that the work be so well supported as to ensure continuance of its publication, whilst it maintains its present high standard.

MISCELLANY.

TRI-STATE MEDICAL SOCIETY OF GEORGIA, ALABAMA AND TENNESSEE will meet in Chattanooga, Tenn., Tuesday, Wednesday and Thursday, October 25, 26 and 27. The following papers will be presented:

1. Eye Symptoms in General Disease, J. L. Minor, Memphis, Tenn.
2. Talipes Equino-varus (with presentation of patients), C. W. Barrier, Rome, Ga.
3. Sequences of Otitis Media Purulenta, T. Hilliard Wood, Nashville, Tenn.
4. Report of 1,050 Strabismus (Cross Eye) Operations, with some Observations on the Same, A. W. Calhoun, Atlanta, Ga.
5. Hypertrophic Rhinitis, Gilbert I. Cullen, Cincinnati, O.
6. Croupous Rhinitis, with Report of Cases, J. W. Long, Randleman, N. C.
7. Special *vs.* General Practice in Medicine, W. J. Killen, Birmingham, Ala.
8. The Present Status of Medical Education in the South, Luther B. Grandy, Atlanta, Ga.
9. Synovitis, J. B. Cowan, Tullahoma, Tenn.
10. A Clinical Study of the Relations between Scarlet Fever and Diphtheria, W. D. Hoyt, Rome, Ga.
11. Pharmaceutical Preparations of the Present Day, John C. LeGrand, Anniston, Ala.
12. Comparative Value of Proprietary and Pharmaceutical Preparations, Harry Wise, Ph.G., Chattanooga, Tenn.
13. The Treatment of Inguinal Hernia, J. W. Handly, Nashville, Tenn.
14. Surgery—Things to Do and Things not to Do, Willis F. Westmoreland, Atlanta, Ga.
15. Treatment of Indolent Buboes. W. B. Rogers, Memphis, Tenn.
16. The Prepuce: Its Uses and Its Dangers, Erasmus T. Camp, Gadsden, Ala.
17. Stricture of the Male Urethra: Its Diagnosis and Treatment, W. L. Gahagan, Chattanooga, Tenn.
18. A case of Injury to Some of the Cervical Vertebræ Combined with Transverse Fracture of the Occipital Bone, R. H. Hays, Union Springs, Ala.
19. Report of a Case of Rupture of the Abdominal Muscles During Normal Labor, J. W. Hallum, Carrollton, Ga.
20. Report of a Case of Intestinal Obstruction, J. F. Huey, Birmingham, Ala.
21. A Few Selected Cases in Laparotomy, W. H. Wathen, Louisville, Ky.
22. The After-treatment of Abdominal Operations, W. E. B. Davis, Birmingham, Ala.
23. Hepatic Abscess, E. B. Ward, Selma, Ala.
24. Report of Treatment of Sterility, J. M. Head, Zebulon, Ga.
25. Extra-uterine Pregnancy, Richard Douglass, Nashville, Tenn.
26. A Case of Imperforate Hymen, Andrew Boyd, Scottsboro, Ala.
27. Puerperal Eclampsia, with Report of Cases Treated with Nitro-Glycerine, R. M. Harbin, Calhoun, Ga.
28. Erythema, Henry Wm. Blanc, Sewanee, Tenn.
29. Epithelioma; Some Experience, M. B. Hutchins, Atlanta, Ga.
30. Drunkenness and Its Gold Cure (?), John P. Stewart, Attalla, Ala.
31. Summer Diarrhœa of Children, G. T. Prince, Whiteside, Tenn.
32. Advanced Theories in Psychical Science, John E. Purdon, Cullman, Ala,
33. Dysentery and the Most Successful Ways of Treating It, D. H. Baker, Gadsden, Ala.
34. Diagnosis of Fevers, J. A. Long, Cleveland, Tenn.
35. Cholera and the New York Episode, Joseph Holt, New Orleans, La.

MEETING OF INTERNATIONAL MEDICAL CONGRESS (American Public Health Association), in the City of Mexico, November 29th and 30th and December 1st and 2nd, 1892. For the convenience of delegates, and all physicians with their families, who desire to attend this meeting, an elegant Pullman car will leave Chicago November 19th. Short stops will be made at all points of interest between Chicago and the City of Mexico. For further information, maps, time tables, etc., address John E. Ennis, D. P. A., Mo. Pac. Ry., 199 Clark street, Chicago, Ill.

OFFICIAL LIST OF CHANGES in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from October 8, 1892, to October 14, 1892.

Capt. Henry P. Birmingham, Asst. Surgeon U. S. A., is granted leave of absence for one month.

Major Daniel G. Caldwell, Surgeon U. S. A., is granted leave of absence for fifteen days.

By direction of the Acting Secretary of War, Par. 3, S. O. 199, A. G. O., August 24, 1892, is revoked, and Capt. Louis M. Maus, Asst. Surgeon U. S. A., is relieved from duty at Ft. Apache, A. T., and will report in person without delay to the commanding officer, Whipple Bks, Ariz., for duty at that station.

First Lieut. Isaac P. Ware, Asst. Surgeon U. S. A., is relieved from duty at Ft. Logan, Col., and will proceed without delay to Ft. Supply, Ind. Ter., and report in person to the commanding officer of that post for duty.

Major Robert H. White, Surgeon U. S. A., is relieved from duty at Ft. Myer, Va., to take effect on the expiration of the leave of absence granted him, and will then proceed to report in person to the commanding officer, Jefferson Bks., Mo., for duty.

Major Daniel G. Caldwell, Surgeon U. S. A., is relieved from duty at Jefferson Bks., Mo., and will report in person to the commanding officer, Madison Bks., N. Y., for duty at that post.

Capt. William C. Gorgas, Asst. Surgeon U. S. A., is relieved from duty at Ft. Barrancas, Fla., and will report in person to the commanding officer, Ft. Reno, Oklahoma Ter., for duty at that post, relieving Capt. John L. Phillips, Asst. Surgeon. Capt. Phillips, on being relieved by Capt. Gorgas, will report in person to the commanding officer, Ft. Myer, Va., for duty at that post.

Capt. Henry L. Turrill, Asst. Surgeon U. S. A., is relieved from duty at Madison Bks., N. Y., to take effect on the expiration of his present leave of absence, and will report in person to the commanding officer, Ft. Riley, Kan., for duty at that post, relieving Major John Van R. Hoff, Surgeon U. S. A. Major Hoff, on being relieved by Capt. Turrill, will report in person to the commanding officer, Ft. Columbus, N. Y., relieving Major Johnson V. D. Middleton, Surgeon U. S. A. Major Middleton, on being relieved by Major Hoff, will report in person to the commanding officer of the Presidio of San Francisco, Cal., for duty at that post.

OFFICIAL LIST OF CHANGES in the Medical Corps of the U. S. Navy, for the Week Ending October 8, 1892.

Asst. Surgeon R. M. Kennedy, from the training ship "Richmond," and to the coast survey str. "Bache."

Medical Inspector T. C. Walton, ordered to the Naval Academy.

Medical Director B. H. Kidder, from the Naval Academy, and to the naval station at Port Royal, S. C.

P. A. Surgeon W. F. Arnold, from the naval station at Port Royal, and to the U. S. S. "Richmond."

ORIGINAL ARTICLES.

SAWS AND THEIR APPLICATION IN NASAL SURGERY.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY ALLEN DEVILBISS, M.D.,
OF TOLEDO, OHIO.

Woakes used small saws, and Siler recommended them for the removal of bone tissue in the nose. Bosworth reported a series of 166 operations of deformities of the nasal septum, with a saw of his own device and since that time they have been used almost exclusively to any other.

It is the best instrument for removing small bony projections that I have used, yet there is trouble in using it where the septum is deflected and a broad surface to be removed.

In these cases soon after we commence sawing, the spaces between the teeth fill up, the saw will fail to cut rapidly, and we are compelled to use pressure, clean the teeth or change saws.

I have also had cases where it was impossible to enter the saw far enough, either below or above, to have stroke sufficient to do any satisfactory work toward the removal of the parts, also in operations which require a larger access to the nasal passages than the natural ones for the removal of tumors from the cavities or naso-pharynx, which require incisions of bone to be made for their removal.

Some years ago I had quite a series of the above class of cases and with the instruments I could command at that time my success was not as satisfactory as I wished for.

It was this that led me to undertake to try to devise a saw so constructed that I could use its extreme end for cutting purposes, attacking the tumor directly in front.

I have been endeavoring to produce such a device ever since, sometimes thinking I had succeeded, at other times failed, but to-day I take pleasure in showing you the instrument that is the result of my prolonged effort, which has not only proven satisfactory to myself but to others.

You will see by examination that it is not much thicker than the ordinary saw and that its edges are protected by steel shields so that it may come in contact with soft parts and not injure them. Being so narrow that they pass into the slot the saw cuts. It can be used in connection with or without grooved director. If the operator uses the director he should place it above the portion that is to be separated from the septum, then pass the shield of the saw along its narrow groove, thus directing it through the surfaces to be cut with precision and certainty. I have seen cases where the grooved director could not be passed above the part. In these cases a hole can be bored through with a twist drill connected to the cable used to run the saw, so that it will do its work quickly. The grooved director can be passed through the opening thus made and the saw used as before described. This is not necessary, as a rule, in hands that have practiced the use of the saw with a view of studying direction.

The shield must be kept in the groove of the director and the cutting end of the saw parallel to a line that would correspond to the side of a normal septum.

The distance which the saw is to be carried into the nasal passages can be determined by measuring first with a probe, the distance from the anterior part of the nose to the posterior surface of the part to be removed, then place this measurement on the saw. This is not necessary to one accustomed to its use as the sense of touch will tell us when it is through. In this way we remove the part much more quickly and with less pain to the patient, and the plane of the part left will be straighter than it could possibly have been made with the ordinary saw used, which is liable to leave an uneven surface.

Bosworth, in his book on diseases of the nose and throat, page 304, makes the following statement in operations for fractured septum with thickening: "Objection has been made to these operations that they result in ulceration. Now, I wish to say, in as positive a manner as possible, that in no case have I had any such result. The subsequent treatment is nothing. The healing process requires no attention. The parts heal up kindly, and, as a rule, with no unpleasant symptoms during the process. It has been charged that bad cicatrices result. Again, I say that I have seen no such result in any case. The mucous membrane re-forms over the cut surface and at the end of two months it would be difficult to recognize the fact that any cutting had been done. Too much importance cannot be laid on the necessity of a perfectly straight, smooth-cut surface. In one or two instances in operating I bent my saw, which is exceedingly flexible, in such a way as to make a hollow cut, sawing in a curve, as it were, leaving a depression on the surface of the septum. Whenever I have made such a mistake there has been exceedingly great annoyance from delayed healing, owing to the fact that mucus and bloody pus accumulated in the depression and formed crusts, and thus markedly interfered with the healing process. And herein, it seems to me, lies an objection to the rougher operation of the gouge and the forceps in removing these obstructions, as leaving an irregular surface for the lodgment of mucus and secretions. We meet with no ulcerations in the nasal cavity, except as a result of syphilis or some blood-poisoning.

"Delayed healing may occur, but not ulceration, after the operation, and delayed healing, I am positive can only be the result of unskillful operating.' Thus Dr. Bosworth testifies to the value of the plane surface.

Knowledge alone is an excellent thing, but knowledge and skill combined are what are necessary for the proper use of any instrument. Whatever saw we may use we must, by seeing, get our starting point and direction, then follow that course even though our light may be shut out. This skill cannot be acquired without patient practice; it need not be on the dead or living human subject because as long as we have butcher shops, material will be abundant. In order to distend the nasal opening for these operations or any otherpurpose, I have devised a nasal speculum which is self retaining if properly introduced. They are made out of steel piano wire and accomodate themselves to almost any form or size of opening without any material increase or decrease of pressure, because of a spiral spring arranged in connection with two rings which hold the nose sufficiently open. This is an advantage as it does not cause the patient pain by unnecessary stretching of the parts and therefore may remain as long as is needed. If it does not sufficiently open the nose for illumination another one may be placed with one ring against the septum the other one against the wing of the nose and neither one be in the way of the operator, whether they are used for explorative or operative purposes. I scarcely ever find it necessary to use more than one, and when I use but one in connection with the saw I always place one ring in the roof and the other in the floor of the vestibule of the nose, thereby making an oblong opening, the long side of which corresponds to the side of the saw and the narrow to its edge, which gives a chance to move the point of the instrument up or down in case the part to be sawed off is so wide as to make this movement necessary.

It will be observed in my paper that I have confined myself exclusively to septal thickenings with or without deflection, at the same time I may be permitted in conclusion to observe that this instrument may be effectively used in any of the various procedures in internal nasal surgery.

TREPHINING FOR MASTOID ABSCESS; WITH NOTES OF THIRTY-TWO CASES OPERATED ON AMONG 3,400 PATIENTS SEEN IN 1889, 1890 AND 1891.

Read before the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich, June, 1892.

BY B. ALEX. RANDALL, M.A., M.D.,
PROF. OF OTOLOGY, UNIV. OF PENN. AND PHILADELPHIA POLYCLINIC.

It is natural that otology should have shared in the general advance of surgery, and that there should be increasing resort to surgical measures in all aural cases where experience has shown that all milder measures are slow or inefficient. How far we will be justified in operative interference in the lines where other measures can often succeed, if persistently employed, or where failure would mean nothing very serious to the patient, are questions which we can leave to the gradual growth of experience. But there is a large and growing group of conditions where we have less free choice. There are cases where not a pound or even a ton of belated cure will avail; where the indications for operation may appear once only accompanied by conditions favorable to success, and in failing to take advantage of that opportunity we may seriously or fatally betray the confidence which has been bestowed in us as medical men. The indications of such conditions are not fully defined, and each case, in some measure, must be judged by itself; but certain principles have been fairly demonstrated anatomically and clinically, and their application in practice must be considered conscientiously by every man who assumes or retains charge of an aural case. The surgical enthusiasm of some men for special operations, or for operating in general, may need to be discounted; yet the fact remains that timidity does not constitute caution, nor is inaction always masterly and conservative.

One of the directions in which surgical intervention is generally called for, and sometimes most imperatively, is the matter of suppurative involvement of the mastoid portion of the temporal bone. Here we have a tract more or less prone to suffer from tympanic inflammation, surrounded by most important structures, and by its anatomical relations liable to have its lesions serious not only in threatening the hearing and other functions, but even imperiling the life.

I believe that there are many who have had such an experience as my own, and many more to whom the same is soon to come; and to these, these notes may have something of help. During the earlier years of my aural work few cases came to view in which questions of life and death seemed to press upon me for a prompt decision. Cases of mastoid empyema were rare and less surely recognized, the indications for operation were ill-defined, and I preferred to drift, congratulating myself upon my "masterly inaction" if the case came through safely, and laying no blame upon my timid conservatism if I failed, especially if I had done the daring deed of cutting down upon the bone, and rested content to proceed no farther. Having never seen a mastoid formally trephined in life, nor done it more than very rarely on the cadaver, its dangers and uncertainties seemed far more evident than its benefits; and cautious consultants restrained me when inclined to proceed at all boldly. Nor indeed, looking back, can I blame myself for more than one or two fatal sins of omission, and those with a saving question whether timely operation would have changed the result. With increased experience, widened practice and the epidemic of "la grippe," I could no longer hold such a position. The cases have multiplied around me in which the question of operation pressed, and there were many where the urgency could not be evaded. In the past fifteen months nearly forty cases of fluctuating swelling or other evidence of mastoid inflammation have aroused my solicitude; and while some have offered no alternative but immediate operation, many have been first vigorously treated with antiphlogistic measures and have fallen into three groups, where either resolution was secured, where operation had to be done later. or where the diagnosis cleared up and a mere superficial glandular abscess was found to constitute the true condition. Simple incision through the soft tissues has sufficed in a group of cases to secure fairly prompt and satisfactory results, no serious necrosis of the bone being found to demand further intervention. Yet there have been at least fifteen cases where it has been necessary to attack the bone, and it is to such that I would especially ask your attention now. The following table gives in brief notes of the thirty-two cases operated on in the three years of 1889—1891:

TABULAR STATEMENT OF MASTOID OPERATIONS DURING 1889-91.

1	1.19.89	E. 721	Mary Price	aged 41	left	Sinus to antrum	Cured.
2	2.8	E	Albert Warner	“ 8	left	Abscess evacuated	“

31	9.15	Pr. 152	Horace Anderson	“ 9	left	Recurrent abscess	“
32	12.30	C. 211	Charles G. Wade	“ 10m	left	Abscess and sequestr.	“

Reviewing the work of the past three years, among upwards of a hundred cases, in which pain, swelling and other symptoms strongly threatened empyema or caries of the mastoid, I find records of thirty-two mastoid operations in which I attacked the bone. The mastoid cases constituted nearly 4 per cent. of the 3,400 new cases seen in this period, and about 1 per cent. were operated upon. A group of doubtful and imperfect records, which I have been unable to verify, ought to slightly lengthen the list; and in another series of cases mastoid suppuration or caries was attacked with curette or chisel through the auditory canal, after the method of Wolff; but neither group is here considered. Previously, in my seven years of service at the Episcopal Hospital and three years at the Children's, an additional series of cases was operated on, as to which I have not taken time to search out the scattered notes. During the first five months of 1892, I may mention, in passing, that I have had ten more operations, so my experience, though small compared to the hundreds of operations of Schwartze or J. Orne Greene, has still given me upwards of fifty operations. Only four deaths are known to have occurred in this series of operations, while ten or more have been noted among the others not operated upon, and this latter list but partially reveals the truth as to the fatality of the affection. In but one instance, that reported to the Am. Otolog. Soc. (Trans. 1891, p. 93), can I ascribe any blame to the operation for hastening death. Yet I am far from enthusiastic as to the harmlessness and urgency of the operation, nor should I be understood as arguing that every other aurist ought to have a similar series of operative cases among the same number of ear-patients.

There are several lessons which have been borne in upon me by these experiences, which promise to be of aid in my future work, and may be of help to others. First, of course, that operation is not always necessary unless the presence of pus is reasonably certain. Vigorous hot fomentations, aided by hot douching of the ear, may secure resolution in most threatening cases, and bring about a cure more speedily, safely and completely than any other method. Second, that pus should be freely evacuated as soon as discovered, and the search for it not limited to the external surface of the mastoid, but that its burrowing in many other directions must be borne in mind, and every reasonable means employed to discover its lurking places. Third, that it is a mistake to incise and evacuate pus collections without an anæsthetic to facilitate thorough exploration. In many cases it may be a real saving of suffering to the patient to avoid the discomfort of ether, yet it is so easy to stay the hand too soon, and leave undone work which is urgently required. General anæsthesia, with its freedom of procedure, is usually requisite. Fourth, that our object should be to remove the pathological condition present to the fullest possible extent, not resting content with the mere securing of drainage. Drilling or otherwise draining the mastoid cells may, therefore, be but a halfway measure and leave the patient to a long and tedious further process of caries and sequestrum formation, exposed for months to renewal of the serious symptoms which may have been abated, rather than relieved. Fifth, that the anatomical and pathological variations which may be present are so great that it is rarely possible to predict what will be met, and that full knowledge must be possessed of the anatomy of the part, the most cautious study by sight and finger and probe must be continually exercised, and the radical removal of all suspected tissue, bony or soft, must be done in all directions in which this is safe, leaving as little as may be to subsequent exfoliation. Sixth, that in the after-treatment the minimum of interference is desirable, the ample external wound being closed by sutures, with little packing, and all subsequent irrigations are to be regarded as undesirable and avoided as far as possible. The duration of after-treatment is in exactly inverse proportion to the thoroughness and success of the primary operation.

IT is suggested, and very wisely, that the stewardesses of our ocean passenger steamships should be trained nurses. In case of sickness they would be more efficient, and they would, from their previous training, be more likely to keep the rooms sweet and wholesome.

OBSERVATION OF A CASE OF PURULENT OTITIS MEDIA, CEREBELLAR ABSCESS AND DEATH IN THREE WEEKS.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY C. H. BURNETT, M.D.,

OF PHILADELPHIA, PA.

The patient was a little girl 5½ years old. She was attacked with acute otitis media January 24, 1892, and allowed by the family physician, a homœopathic one, to suffer a week without paracentesis of the membrane. At the end of that time spontaneous rupture occurred and muco-pus flowed from the meatus. The child, however, drooped and complained of headache, though she was free from earache. Gradually, by the end of the second week, the patient showed well-marked symptoms of cerebral abscess, and at the end of the third week the case was abandoned by the irregular practitioner and other consultants were called in. I recognized the condition of the patient when I was summoned to see her on February 10, 1892.

At my suggestion, Dr. Wm. W. Keen was called in with a view to his trephining for relief of the cerebral abscess. The precise position of the latter could not be located. Dr. Keen first opened the mastoid cavity, finding it filled with cheesy pus. He then made an inch trephine opening, the centre-pin being placed 1¼ inch above and behind the external auditory meatus. Exploration of the anterior and middle fossæ of the skull failed to reveal pus in either fossa. A grooved director passed into the temporo-sphenoidal lobe also failed to discover pus. The child recovered well from the ether, but gradually sank and died eleven hours after the operation. Post-mortem examination thirty-six hours later revealed an abscess in the right hemisphere (side of affected ear), containing 2 fluid ozs. of odorless pus.

Straight instruments have been found preferable to those set at an angle with the handle. The patient should be lifted as high as is safe in the anæsthetic state, which can be effected by having the head and shoulder piece of the operating table hinged. The teeth should be in a good condition before the operation of excision is performed.

In two cases of chronic catarrhal otitis media I have operated on both ears, with fair results, considering the degree of the deafness and sclerosis.

In a case of chronic purulent otitis media, in a boy 12 years old, excision of the swollen and granulating membrana tympani, with the malleus, was followed by cessation of discharge and an improvement in the hearing for isolated words, from 2 feet to 20 feet.

EARLY DIAGNOSES OF MASTOID DISEASE AND OPERATION AS A LIFE SAVING MEASURE, IN THE PREVENTION OF PYÆMIC AND MENINGITIC COMPLICATIONS.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held in Detroit, Mich., June. 1892.

BY D. MILTON GREENE, M.D.,

OF GRAND RAPIDS, MICH.

[ABSTRACT.]

Five cases of suppuration in the mastoid cells following acute suppurative otitis media, without external signs of mastoid disease.

No pain referred to mastoid. Acute pain lasting until perforation of membrana tympani.

Temperature in four cases reached 104 or above, and in one only 102, before operation.

Operation in four cases with recovery. No operation in one, which resulted in perforation, pyæmia and death.

Early diagnosis made in latter case.

Autopsy.

Pain, redness, swelling and œdema over mastoid, not essentially signs of suppuration in cells.

Opened lateral sinus in one case with no bad effect.

ABSTRACT AND REMARKS ON A CASE OF THE SO-CALLED BEZOLD VARIETY OF MASTOIDITIS; MASTOTOMY; CRANIOTOMY; DEATH.

AUTOPSY: ABSCESS IN TEMPORAL LOBE AND CEREBELLAR HEMISPHERE; THROMBO-PHLEBITIS ON BOTH SIDES.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY HERMAN KNAPP, M.D.,

OF NEW YORK.

Mr. President:—My paper contains a detailed description of one of the most important and instructive cases of my aural practice. It is, however, too long to be read before this Society. I, therefore, would beg permission to read only a résumé of it, and some general remarks, which I offer for publication in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, if acceptable, whereas I intend to publish the case in full in *The Archives of Otology* (July number, 1892).

If we recapitulate the history of the case, we find a young woman of good constitution, suffering during the course of a year from repeated attacks of acute naso-pharyngeal catarrh, extending into both ears. The left ear recovered. The fourth and later attacks showed implications of the right mastoid with marked meningitic irritation. She was pregnant; during the last months the attacks were more severe. The upper part of the sterno-mastoid become red, swollen, and painful; ten days after her confinement her physician made a deep incision into the swollen head of the muscle, liberating a good deal of pus. The relief being only temporary, I opened the mastoid from base to tip, found pus in the upper part, and kept the wound open by a perforated silver tube. The patient felt relief, but soon had a pleuritic exudation as an intercurrent disease, which disappeared in less than two weeks. Discharged from the hospital as cured she felt well for two weeks, then symptoms of cerebral irritation returned and with varying intensity lasted until her death, three months later. These symptoms were: Persistent headache, nausea, occasional vomiting, vertigo, stupor, impediment of speech, loss of appetite, constipation. The pulse at first varied between 70 and 88, later sank to 60 per minute, the temperature was between 98.4° to 101°, never changing rapidly. There were no convulsions, deliria, chills or abnormality of sensation. The ear never gave her any trouble, and there never was any discharge from the ear canal, though the drumhead and adjacent portion of the ear canal was red and bulging. Two months before death a sudden swelling was noticed below the head of the other (*left*) sterno-mastoid muscle. The eyes, examined with the ophthalmoscope, were found healthy until the last month, when the development of optic neuritis could be distinctly watched. The extension of suppurative ear disease being diagnosticated, craniotomy was advised, but not consented to until the day before the patient's death.

The operation was made at the patient's house. The opening into the mastoid was enlarged and extended into the cranial cavity by an opening 3 cm. by 2 cm. Dura-mater and lateral sinus found healthy. Then the wound was extended into the tympanic attic by enlarging the mastoid antrum and removing part of the posterior wall of the ear canal with the chisel. No pus being found in the tympanic cavity and the bone being thick and hard, the middle cranial fossa was opened by chiseling a hole 2 cm. in diameter through the squamous portion of the temporal bone, beginning 1 cm. above the ear canal. No extra-dural suppuration was present. The dura-mater and the superficial layer of the brain were incised but found healthy. In the course of the operation the patient became pale and breathless. She was sustained by hypodermic injections of alcohol and by artificial respiration, the latter being kept up until the end of the operation. On account of her feeble condition I desisted from making exploratory incisions or punctures into the brain substance, considering the case then as absolutely hopeless. After the operation, even after the discontinuance of the artificial respiration, she rallied for three quarters of an hour, but then suddenly collapsed and died.

The *autopsy* showed, 1. A perforation in the medial bony surface of the tip of the mastoid process, verifying the diagnosis of the Bezold variety of mastoiditis. 2. The upper part of tympanic cavity densely filled with granulation tissues, but free from pus. 3. The right lateral sinus (that of the diseased ear), healthy, only filled with dark clotted blood. 4. The dura healthy throughout. 5. The pia over the right temporal lobe and the right cerebellar hemisphere milky, its small veins filled with pus. 6. The sinuses in the median line, those adjacent to the median line on the right side, and all the sinuses on the left side, furthermore, the left internal jugular vein as far as the swelling noticed underneath the upper portion of the left sterno-mastoid muscle, filled with pus (purulent thrombo-phlebitis). 7. In the right temporal lobe an abscess of the size of a walnut, and in the right cerebellar hemisphere another of the same size. 8. The remainder of the brain, especially the ventricles, normal. 9. Microscopic specimens and cultivations from the abscesses on the temporal lobe showed a moderate quantity of small bacilli, but chiefly the staphylococcus pyogenes aureus. Examination and cultivation of pus from the cerebellar abscess were negative.

Remarks.—This case is an example of an acute aural catarrh, leading to death through extension into the mastoid and cranial cavities. There never was otorrhœa, yet there was suppuration in the mastoid. No signs of otitis externa having been noticed the pyogenic germs must have travelled from the naso-pharynx (she suffered from acute attacks of coryza) through the Eustachian tube into the middle ear, and through the antrum into the mastoid process, here developing that slow form of mastoiditis which Bezold has so masterly described. This form is distinguished by a tendency to seek an outlet for its inflammatory products at different places along the inner table of the bone, viz.: *a.* Perforating it on the medial side of the tip and extending down into the neck alongside the sterno-mastoid muscle. *b.* Perforating the posterior wall of the ear canal and discharging its products through a fistula in the canal or through the tympanum. *c.* Perforating the cranial cavity, producing extra-dural suppuration and cerebral or cerebellar abscesses. I have seen examples of each of these varities of this form of mastoiditis, to which of late so much attention has been paid.

In our case the *course of the disease* was as follows: Attacks of coryza for several months. In September after an exposure by lying in the grass and being chilled, a violent attack of otitis media catarrhalis, in both ears, which improved, but was not completely cured. Four weeks later the first symptoms of mastoiditis. Improvement again, then in two months after an evening of gaity, the first cerebral symptoms with swelling of the mastoid extending downward. Evacuation of pus below ear brings relief for two weeks. Large opening of mastoid affords relief for four weeks, in spite of an intercurrent pleuritic effusion. Then the cranial symptoms are marked with short remissions. They are not so clear as to admit of a special diagnosis defining the nature and location of the morbid process. Death from cerebral abscess and thrombo-phlebitis.

The operation of craniotomy was done in the right way, and I would, if a case occurred, do it in the same manner again, only sooner. The uncertainty of a special diagnosis, not the surgical procedure, is the great difficulty in these cases, upon which also v. Bergmann dwells in his classical monograph on the surgical treatment of brain disease (1889).

Symptoms of meningitic irritation are marked in a great number of acute and sub-acute ear diseases, which recover by care without surgical interference. I am afraid that there is at the present day too great a tendency to open mastoids and skulls. Precision in the determination of the indications when or when not to operate can only be obtained by a critical comparison of many fatal cases, especially when post-mortem examinations have been made. As exploratory operations, such as gynecologists now practice laparotomy, both mastotomy and craniotomy are, in my opinion, not yet harmless enough to be justifiable in many cases.

Our case was remarkable by the absence of objective symptoms upon which commonly so much stress is laid.

1. There evidently was suppuration in the mastoid long before external swelling indicated it.

2. The absence of otorrhœa through the whole course is also remarkable and exceptional.

3. There was sinus thrombosis of great extent, without the common symptoms of rapid rise and fall of temperature. I measured the temperature whenever I called, and the sister of the patient did it in my absence, twice daily. It never rose above 101°. The sudden swelling at the left side of the neck, the side of the healthy ear, took me by surprise. It was peculiar in its shape, hard and round, about 2 cm. below the tip of the mastoid, with a sharp inferior limit. Ordinarily, the thrombosed jugular can be felt as a hard and painful cord along the side of the sterno-mastoid muscle. Each of the neurologists who examined the case with me thought that thrombo-phlebitis could be excluded.

4. The sinus thrombosis was more marked on the

side of the healthy ear. I can explain this only by the supposition that the formation of abscesses in the brain and cerebellum preceded the thrombo-phlebitis, and that the clotting of the right lateral sinus interrupted the circulation on the side of the diseased ear. The purulent contents of the small veins in the pia over the abscesses were emptied into the torcular and conveyed by the left lateral sinus to the left internal jugular. The abrupt swelling of the latter can be explained by plugging of the lower part of the vein with clotted blood before liquifaction of the thrombus had taken place, in the same way as the pus had been prevented from passing into the right internal jugular by blood clots in the lateral sinus found at the autopsy. The case shows how occult the objective symptoms of cerebral thrombo-phlebitis may be, and how unexpected the places in which they manifest themselves.

5. The cerebral abscesses showed, aside from the insignificant fever, only one objective symptom during the last month, that was the double *optic neuritis*. Choked disc, as far as experience has proven, is an inconstant and apparently late symptom of otitic brain disease. It does not always indicate a fatal termination of the case, and disappears when the patient recovers, even in cases of pyæmia.

I will conclude this paper with some remarks on the significance of the subjective cerebral symptoms in middle ear inflammation.

1. Transient headache, nausea, vomiting and dizziness in acute cases indicate meningitic irritation. They almost all recover with or without mastotomy, only a few exceptional cases of fatal termination being on record.

2. Persistent headache, nausea, vomiting, and dizziness, especially when the discharge from the ear diminishes, signify the transition of meningitic irritation into real meningitis, and indicate surgical interference, paracentesis of the drum membrane, especially the membrana flaccida when bulging, or opening of the mastoid à la Schwartze or Küster.

3. The above symptoms, with delirium, stupor, impediment of speech, chills, spasms, drowsiness and coma, signify fully developed intra-cranial suppuration. In the majority of such cases it may be difficult or impossible to discriminate between thrombo-phlebitis, extra-dural and cerebral or cerebellar abscess. The special diagnosis and localization, when strengthened by valuable objective symptoms, such as painful swelling and hardness of the internal jugular vein (sinus thrombosis), localized pain on percussion of the skull (abscess), a fistula in the cranial bones (extra-dural suppuration), may justify, even demand surgical interference, namely, opening the posterior cranial fossa to ligate and cleanse the lateral sinus, or opening the posterior or middle fossa to liberate the extra-dural accumulation of pus, or opening the posterior or middle fossa to evacuate an encephalic abscess.

Of all these varieties, a certain, though small number of cases is known in which the diagnosis was correctly made and the operation successfully performed.

Discussion.

Dr. Frothingham:—I speak first in the discussion of these papers, as one of the cases, the fifth reported by Dr. Greene, was seen by me and a more full and complete report is necessary for its proper consideration. In this case there had never been the least indication of mastoid disease that could be determined by local symptoms, or inferred as a probable explanation of any other symptoms. The pain had been in the ear and down the neck in the course of the internal jugular vein, occasionally some pain in the head near the vertex. There was no swelling or tenderness over the mastoid, or in that region, nor was there any feeling of fulness there, or any feeling of discomfort even on percussion over it.

On the fourth day of attack of middle ear disease, there were symptoms of metastatic pyæmia. Abscesses began to appear in the subcutaneous cellular tissue, and the severe rigors and other symptoms pointed to venous trombosis and pyæmia, rather than mastoid abscess. Pyæmia in acute mastoid abscess is not common. Its early appearance in this case, together with the other symptoms, indicated a more direct extension of the disease to the lateral sinus than would likely result from mastoid abscess, even had there been symptoms of retained pus in the mastoid cells. The early and severe rigors were more like those that characterize inflammatory thrombosis. The patient, after the continuance of acute symptoms for about two weeks, had begun to improve, and for a period the temperature had been nearly or quite normal. Then the high fever and frequent chills recurred, new metastatic abscesses began to form in the subcutaneous cellular tissue in different parts of the body; there was nausea and vomiting also. It was about five or six days after these symptoms had reappeared that I saw the case. There was at that time a hardened, cord-like swelling of the internal jugular vein, extending two-thirds of its course down the neck. The least jar, or pressure, or movement of the head caused great pain in this region, and the patient found it necessary to have the head inclined to that side in order to avoid the suffering caused by any traction of the muscle over it. There was nothing to indicate mastoid disease except the fever, and this was explained by the evident venous thrombosis and pyæmia which plainly existed. Besides, it was more like the fever that attends this condition than that of mastoid abscess. The patient seemed to have but a short time to live. With these symptoms I did not advise artificial perforation of the mastoid. I said to the attending physician and the friends of the patient that it was possible that there was pus in the mastoid cells, but it was not probable. That we could not advise operations on possibilities, but only upon probabilities. We have as yet no infallible rules to guide us in making this operation. While some cases are plain, and there are rules that seem imperative, there are yet cases with symptoms so obscure that no rules can be formulated for our guidance. Dr. Buck tells us that some years ago he formulated rules that he thought simple and practicable, but that further experience taught him that there must be numerous exceptions. It has happened to me twice to perforate the mastoid process where the symptoms of mastoid abscess were very well marked, and yet I found no pus, or other evidence of disease. The same has happened very often in the experience of others. Post-mortem examinations have been made when the symptoms of mastoid abscess had been well marked and it was confidently expected that pus would be found, and yet none was found after diligent search. While the operation of artificial perforation is comparatively safe, it is not without danger. Schwartze, who has had a most extensive experience in this operation, and has studied extensively the literature of the subject, attributes two per cent. of death to the operation itself. It should, therefore, only be advised where there is a probability that retained pus or other disease in the mastoid is the cause of the dangerous or unpleasant symptoms from which the patient suffers.

In giving the advice which I did in this case I had to decide at once with the evidence then before me, remembering that even in cases where the operation otherwise might be indicated, that when metastatic pyæmia is well marked the time when a useful purpose can be subserved by artificial perforation has probably gone by.

After a very careful consideration of this case since the post-mortem examination was made, I have been unable to find any reasonable excuse for an operation on the mastoid, based upon the symptoms that existed during the course of the disease. I am aware that without local symptoms, mastoid abscess has been diagnosed by the study of the temperature alone. But these were cases in which, by the study of the symptoms, other causes of the fever could be excluded, and not in cases like this, where without signs of mastoiditis venous thrombosis and pyæmia certainly existed, and better explained the fever than mastoid abscess could. From what we, at present, know of this disease, there will probably always be anomalous cases that will baffle diagnosis, and can only be determined by post-mortem examination. And cases like the one reported can not be operated upon, unless we establish the arbitrary rule to perforate the mastoid in all cases where middle ear disease exists, together with fever, either high or low, or any cerebral symptoms of threatening character, regardless of their nature, no matter what other conditions may be present that fully explain their existence.

Dr. Chisolm, of Baltimore, said, as to mastoid trouble, he feels assured that inflammation of the cells exists much more frequently than is generally believed. Those who have occasion to examine sections of the temporal bone are aware of the great variations in the size of the communication from the drum cavity into the dural cavity of the mastoid. When we remember that the membrane lining each is a continuation of the other, we can easily explain why the discharge is often so abundant, owing to the extensive mucous surface. Should the opening be small, as we sometimes find it to be, its closure through swelling of the soft tissues may incarcerate pus and bring about mastoid abscess. As to instrumental interference, in many cases the indications are clear and demand immediate action. In other cases the symptoms are so illy defined that prudent surgeons abstain from making experimental mastoid openings. I have operated on some patients where I thought the indications were clearly defined and yet found no pus. In one such an autopsy exhibited a general phlebitis of all the venous sinuses, but no pus. In another case where we would have opened the mastoid but found the patient too low to undergo the operation, a large blister covering the back of the neck, and one-half drachm doses of the tincture of the muriate of iron, suggested the doing of something for the dying man, brought about such good results as to eventuate in time in perfect restoration. He has seen cases of profuse discharge of long continuance, sequel of acute aural catarrh, with cerebral symptoms coming on in the course of the disease, irregular walk, beside severe pain over the mastoid region, get well without mastoid section. Such cases would also get well, no doubt, with the section, to which much good would be attributed undeservedly, as the sequel has shown. The difficulty in diagnosing the cases that should be operated upon is the more conspicuous the larger our experience, and I find myself shrinking from doing needless work, even when it is not accompanied with much danger in the operative manual. Not to be too hasty in adopting the heroic treatment is a good surgical quality.

Dr. Knapp:—Dr. Greene spoke of the quantity of pus being so large that it could not originate in the tympanic cavity alone, and pointed to the presence of an abscess. I think that the mucous membrane of the tympanic cavity with the adjacent air cells are sufficient to secrete large quantities of pus, just as we see it in the conjunctiva.

The so-called post-aural abscess is, the more I am acquainted with it, regarded to originate in a suppuration of the middle ear, mostly of the attic. The fistula may be difficult to detect, but the more carefully I seek for it the more frequently I find it, sometimes distant from, for instance, as far as an inch above the insertion of the auricle.

The difficulty in the management of middle ear and mastoid inflammation lies in the diagnosis more than in the treatment. Different symptoms, pain, temperature, lack or presence of discharge, presence or absence of external signs are of value, but none of them in itself is pathgonomonic. We require the appreciation of all the symptoms, in their combination, to arrive at a diagnosis in which there may be one symptom prevalently to guide us in the localization of the lesion and in our action. This we ought to keep in mind also during the progress of an operation. The operation of the mastoid does not involve so great a danger as craniotomy, but I think, with Dr. Frothingham, neither of them ought to be done on a possibility, but on a probability, and in brain surgery only on a probability approaching certainty.

Dr. Burnett said he was in entire accord with Dr. Knapp in what he had said regarding mastoid symptoms and treatment. He would add, however, that in his opinion, no one should open the mastoid in chronic mastoid disease, or in any case where cerebral symptoms had shown themselves, without being prepared to go further and open the cranial cavity. Regarding peroxide of hydrogen, Dr. Burnett would say that he has observed denuded bone on the promontory heal and the membrana tympani close under the use of peroxide of hydrogen instilled into the cavity.

Regarding acute mastoid disease following acute otitis media, he would say that he has never seen a case demanding opening the mastoid, unless the local treatment of the ear after the opening in the membrana had been made, or had occurred spontaneously. After the membrana is opened nothing should be thrown into the drum cavity for fear of irritation and possible mastoid complications. The mere presence of pus in a previously healthy mastoid cavity, in acute otitis media is not sufficient reason for opening the mastoid unless the mastoid symptoms are very severe and increasing, having been present a week. There should be no haste to open the mastoid as resolution of the intra-mastoid congestion will surely take place without such operation.

Dr. Seiss thinks much of discussion bears more upon cerebral surgery than upon aurist's work. Regards blistering the mastoid, when used in connection with proper treatment through the external canal and Eustachian tube, of very great value.

TREATMENT OF OPACITIES OF THE MEMBRANA TYMPANI, ACCOMPANIED WITH DEAFNESS.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY FRANCIS DOWLING, M.D.,
OF CINCINNATI, O.

A distinguished writer on ear diseases says that between the ages of 20 and 40 nearly every third person has some difficulty of the hearing with one ear at least. Although this statement may be somewhat exaggerated, still we know from our everyday experience in practice that there is a very large number of people along towards middle life who no longer hear well with one ear at least, and that, while during the years from 20 to 40, the number who are completely deaf is comparatively few, still the number whose hearing power is below normal is very great.

If we examine these cases carefully, we will find that a fairly large percentage of them present ears with no evidence of disease. In a still larger number, however, the drum-head of one and often of both ears, present conditions of opacity either circumscribed or general, with more or less thickening of the membrane.

These opacities, when present, are usually the result of an antecedent inflammation of the external meatus, or a catarrh of the cavity of the tympanum, or senile changes in advanced age. When, in consequence of the inflammation either external or internal, exudation takes place into the substantia propria of the drum-head, the opacities thus formed are permanent and cannot be removed by any species of medication.

About two years ago I instituted a series of experiments in the treatment of these opacities of the drum-head with a view to clearing them up and restoring the drum-head to a fair degree of usefulness, and thus getting an improved condition of the hearing. The treatment consisted mainly in penciling the drum-head and the adjoining parts of the external meatus with various medicated solutions.

Altogether, something like a dozen different remedies were used, in solutions of water, glycerine, olive oil and albolene. The applications were made from once a day to twice a week, and were continued from one to eight months in each case.

I obtained better results from an oily solution of phosphorus and strychnia in different strengths than from any of the other remedies tried.

The remedy, I think, does good by directly stimulating the membrana tympani, thus increasing its nutritive activity, which in these opacities is usually below par, and thus getting rid of the opacities by absorption of the exuded or deposited material giving rise to them.

I found the influence of the remedy particularly well marked in cases of opacities arising from catarrh of the cavity of the tympanum caused by attacks of la grippe during the late epidemic of that disease. In some of these cases the improvement in the hearing was very great.

In the opacities in elderly people as a result of senile changes the remedy sometimes did a great deal of good, and then again, there was no apparent improvement, even after months of patient treatment. In about 10 per cent. of these cases I succeeded in improving the hearing by the use of this remedy. These elderly people are often very thankful even for a slight improvement in their hearing, and are willing to spend a goodly share of time and money in furthering any treatment that will secure this end.

In cases which present a parchment-looking general opacity with abnormal thickening of the membrane, applications of this remedy or any others of its kind will, in my opinion, do no good. In cases of this nature attended with great loss of hearing power, the only remedy that promises any permanent relief in improving the deafness is a total excision of the drum-head. Making an opening in the membrane by any of the methods that have as yet been proposed does good only for a time, as the opening, by whatever method it may be made, is sure to close up in a comparatively short time, when the deafness again returns.

Probably one of the most ingenious of the appliances that have been devised for keeping the opening from closing is Politzer's eyelet, but even this does not always work well in practice. To begin with, it is a very difficult and tedious thing to get it in place, and then after one has succeeded in doing this the contrivance is readily displaced, during a fit of coughing, sneezing, etc., falling either outwards into the external meatus, or still worse, inwards into the cavity of the tympanum.

I wish to submit here a few cases taken at random from my note book:

Case 1.—Mr. N., aged 40, was treated in January, 1887, for an acute inflammation of the external meatus of the left ear, which he stated was the result of a strong ear injection which he used to cleanse his ear of wax. The disease terminated in recovery. In December, 1891, he came to me, complaining of loss of hearing and a feeling as if a foreign body was in the ear. On examination the drum-head presented a uniform opaque color. The outlines of the malleus and incus could not be distinguished. The watch could be heard at 6 inches from the ear—the right ear had been deaf from childhood. The drum-head and cartilaginous portion of meatus externa was penciled with a solution of 1 gr. to the oz., every second day for a month, and twice a week for two months longer. At the end of this time the hearing power had increased so that the watch was heard at 14 inches.

Case 2.—This was the case of an old man aged 76, who came to me October 6, 1890, complaining of great difficulty of hearing, and was very sensitive about his condition. He had tried everything that had been recommended to him; had tried quack doctors and regulars without getting relief. On examination I found both drum-heads studded with opacities of a calcareous deposit. In the right ear there was a crescentic-shaped patch that occupied half the surface of the membrane. The watch could be faintly heard on both sides when placed in immediate contact with the ears. There was no history of disease of the middle or external ear. I applied a 1-gr. solution in this case, but soon increased it to 2 grs. The treatment was kept up until January, 1891, when there was an increase in the hearing distance of 3 inches by the watch for the right ear and 5 inches for the left ear.

Case 3.—Miss W. has complained of difficulty of hearing for over a year. Had a gathering in her right ear years ago, during an attack of measles. Examination reveals quite a large perforation of the drum-head of the right ear, which probably dates from the attack of measles. She hears a watch at 10 inches with the right ear. The left drum-head is intact, but considerably thickened; the watch is heard at 3½ inches with this ear. This case was under treatment from July 20, 1890, until January, 1891, when the hearing distance had increased to 12 inches with the left ear, the one treated.

Case 4.—Mrs. G., aged 52. In this case the deafness dates from the birth of her last child, now aged 16. Both ears are affected. The hearing distance for the right ear is 28 inches, that for the left ear only 6 inches. Both ear-drums are opaque. A 4-gr. solution was used in this case, but the strength of the solution was reduced to 2 grs. to the oz. on her complaining of a disagreeable feeling in her ears on account of the treatment. The case was treated about a year, marked improvement in the hearing.

Case 5.—This is the case of a young woman aged 25, who came to me in November, 1890, complaining of difficulty of hearing in the left ear. There was a marked general opacity of the drum-head of the affected side; the other was about normal in appearance. Here there was a history of catarrh of the middle ear. I treated the case about two months and gained some improvement, but at the end of this time the patient got tired of the treatment and I lost sight of her.

Case 6.—Mr. S. came to me in the fore part of January of this year, and is still under treatment. He is 60 years of age, and has had difficulty of hearing since he was 40 years of age. Here I used a 4-gr. solution. He could not hear the watch even when placed in contact with the right ear when he came to consult me; now he hears at 1 inch, and at 4 inches with the left ear. The opacities in this case are undoubtedly the result of senile changes.

Discussion.

Dr. Seiss thinks the paper of Dr. Dowling very valuable; has used iodine ointment (10 per cent. in lanolin), with very good results in many cases of aural sclerosis.

Dr. Dowling, in closing the discussion, said: A distinguished professor of surgery in a German university used to say to us that when we got into practice the big operations would fill our heads, but the small ones our pockets. You will all subscribe to this as a truism. The big operations, especially on the ear, do not come to us every day, but a large number of cases do come to us claiming treatment for opacities of the drum-head accompanied by more or less deafness. The patients are doleful in appearance and equally doleful in spirits. They implore us to do something for their failing hearing. Often they get no encouragement from the physician.

The results of my experience in the treatment of these cases I have given you to-day in a terse form in my short paper. I hope others of the gentlemen present will give the remedy a faithful trial and report the results of their treatment at the next meeting of the Association.

In answer to the questions that have been asked I would say that the remedy ought to be increased from 1 up to 5 grs. to the oz. according to the degree and standing of the opacities of the membrane of the drum-head. Furthermore the treatment ought to be kept up for months, and the patients should be told at the start that they need expect very little improvement in their deafness under two or three months' treatment. If the larger doses cause undue stimulation of the membrane with a sense of fulness in the ears, the dose should be reduced, as it is apt to produce a certain amount of giddiness. This occurred in two cases which I treated, but vanished on reducing the dose.

Perforation of the Intestine by a Spoon.—Dr. Libotsky reports the case of a woman in the eighth month of pregnancy who was suddenly seized with the symptoms of acute peritonitis. She died in a few hours, and at the autopsy it was found that the duodenum had been perforated by a silver teaspoon, and the spoon itself was found lying in the peritoneal cavity. It was ascertained, on inquiry, that the woman, while suffering from post-influenzal mania two years before, had swallowed the spoon with suicidal intent. *Centralblatt fur Gynäkologie.*

PEROXIDE OF HYDROGEN AND ITS USE IN EAR DISEASES.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY WALTER B. JOHNSON, M.D.,
OF PATERSON, N. J.,
SURGEON TO THE PATERSON EYE AND EAR INFIRMARY.

Peroxide of hydrogen, H_2O_2, as it is popularly called, is chemically and correctly the dioxide of hydrogen. It was discovered accidentally in the year 1818 by a French chemist, M. Thenard, but was little used either in manufacturing or in the arts until within the last decade. Pure anhydrous peroxide of hydrogen is a liquid of syrupy consistence, colorless, having an acid reaction, yielding four hundred and seventy-five times its own volume of oxygen on decomposition. The compound is very unstable, constantly on the slightest exposure undergoing decomposition and breaking up into its component parts nascent oxygen and water.

Bizett reports that the pure solution, anhydrous, readily destroys living tissues. Marchand writes "whatever will be the concentration of the peroxide of hydrogen, as long as it is made by the process which I employ in manufacturing the medicinal H_2O_2 it is always a harmless remedy, *but it is* unnecessary to make it more than fifteen volumes for medical purposes."

Peroxide of hydrogen (medicinal) is a three and one-fifth per cent. solution of the dioxide in pure water, from which all irritating or injurious properties have been removed; it yields about fifteen times its own volume of oxygen and is commonly called a fifteen volume solution.

In consequence of the instability of the compound, and to prevent its decomposition, the medicinal solution is slightly acidulated by the addition of minute quantities of hydrochloric and phosphoric acid.

It is slightly acid in reaction, colorless, almost tasteless and odorless, and will if tightly corked and not exposed to light, or a temperature higher than sixty or seventy degrees Fahrenheit, retain its properties for an indefinite period. It may be used in full strength, or if apparently irritating to the patient, it may be reduced to a one per cent. or stronger solution by the addition of distilled or carefully boiled water. It should be applied by glass or hard rubber applicators or sprays, as irritating and dangerous chemical combinations occur as a result of its contact with some metallic substances.

No solution should be used unless it is thoroughly reliable, fresh and free from injurious impurities; the ordinary commercial article is of no value for medicinal purposes, being irritating in its effect and unsatisfactory in the results obtained, in addition to holding in suspension poisonous chemicals.

A chemically pure fifteen volume solution is entirely harmless either for internal or external use, and in this possesses a decided advantage over any of the other drugs used for similar purposes, which approach it in efficacy as a destroyer of pus, bacteria or germs.

The solution, if in perfect condition, upon its application to any diseased surface of the skin or mucous membrane, immediately undergoes decomposition, the nascent oxygen which closely resembles ozone in its chemical effects, is thrown off and enters into affinity with the pus, bacteria or germs present, the pus is destroyed and the albuminoid matters of the secretion are coagulated, the germs and bacteria are annihilated. The nascent oxygen, which is the valuable constituent for cleansing, disinfecting and destroying germs, is in consequence of its instability rapidly converted into oxygen during the reaction. The chemical action of the solution if fresh occurs immediately upon its application and causes the formation of large quantities of white or yellowish colored froth.

The peroxide solution is much more active than any of the other remedies used for the destruction of microbes; the following table, which has been arranged after exhaustive experimentation, by Charles Marchand, the chemist, who manufactures the medicinal solution which is in most general use by medical men, is intended to illustrate the comparative efficacy of various chemicals, in the destruction of the microbes present in half a gram of diphtheritic membrane. The peroxide of hydrogen is claimed by this table to possess qualities as a destroyer of microbes not approached by any non-poisonous drug, and exceeding in efficacy most of the poisonous germicides.

The mixture or solution used contains like the peroxide solution three and one fifth per cent. of the active constituent.

QUANTITY OF THE MIXTURE OR SOLUTION REQUIRED TO ANNIHILATE MICROBES.

	CUBIC CENTIMETRES.
Glycozone (harmless)	0 75
Biniodide of mercury	1 00
Biniodide of silver	1 33
Marchand's peroxide of hydrogen, medicinal (harmless)	2 00
Bichloride of mercury	3 00
Nitrate of silver	5 00
Hypochlorite of lime	9 00
Chlorine gas (aqueous solution)	10 00
Iodine	10 00
Bromine	24 00
Iodoform (when fresh)	28 00
Salicylic acid	40 00
Muriatic acid	100 00
Carbolic acid	128 00
Permanganate of potash	140 00
Chlorate of potash	158 00
Alum	180 00
Tannin	190 00
Common salt	196 00
Sulphide of calcium	201 00
Boracic acid	300 00
Sulphurous acid	325 00
Lactic acid	360 00
Chloride of iron	371 00

The pus or blood-corpuscles which come in contact with the hydrogen solution are immediately destroyed by the chemical action; it is not necessary to remove the resulting froth; it should be allowed to remain even when other applications are to be used, as it forms a protective for the exposed tissues and does not interfere in any way with the effect of any other desired medication. Glycozone, which it is claimed possesses qualities as a destroyer of germs greater than the peroxide of hydrogen itself, is recommended for use in the subsequent treatment of diseases, in conjunction with it. Glycozone is a preparation of chemically pure glycerine saturated with fifteen times its own volume of ozone under pressure; it is quite different from the peroxide of hydrogen medicinal, and does not part with any of its ozone upon application to diseased tissues; it is intended for use in place of the many astringent or healing applications so much in vogue. It, as well as any application which the physician desires, may be used after the peroxide has been applied with better effect than if the wound was cleaned by ordinary methods, but no application should be made until the pus, etc., is entirely destroyed by the hydrogen solution

The effect of peroxide of hydrogen upon suppurative diseases of the ear has been frequently demonstrated. The full strength fifteen volume solution may be used in nearly every case; infrequently it will cause a moderate amount of pain, in which case the strength of the solution should be reduced by the addition of pure water.

The solution should be applied by syringing, dropping it, or carrying it into the ear on a cotton swab; the immediate effect is the production of a white or yellowish brown froth which will continue to form as long as there is any purulent or albuminoid matter for the drug to act upon. When no more gaseous emanations are present the ear will be found free *from pus and perfectly clean.*

The peroxide solution, it is claimed, has many advantages over any of the other germicides for cleaning deep cavities; its susceptibility to use in any quantity without danger of toxic effect; that the pathogenic bacteria of any species are totally and rapidly destroyed; the ability not only to destroy the products of decomposition and fermentation, but by the quality of effervescence during decomposition to carry forward and without the wound all such products, which it would be difficult to reach with ordinary solution by syringing or injection.

Any remedy may be used in the treatment of the disease subsequently to the application of the solution, the effect of the application itself being simply to render the parts perfectly aseptic and place them in a favorable condition to assist nature's reproductive process.

The application should be made every day, or at least every second day by the physician in charge of the case; the patient should be directed to drop five drops of the solution in the ear three times each day after thoroughly wiping out as much pus as can be easily removed; the glycozone or some of the other applications in general use should be applied immediately after the ear is thoroughly cleaned. In catarrhal otitis it is claimed that in addition to a specific effect on the catarrhal condition the peroxide of hydrogen medicinal has proved of great use in soothing the mucous membrane and rarefying the air in the middle ear, the Politzer bag being used to inflate the tympanic cavity immediately after the application, thus forcing the solution into the middle ear in an effervescing condition.

The peroxide solution may be used advantageously in the treatment of mastoid disease after an incision has been made. The action of the remedy upon bone denuded of its periosteum, and even upon carious or necrotic bone, is unique; it causes a disintegration of the molecular particles and they are gradually subdivided and carried away in the frothy product of the chemical action, until a healthy surface appears upon which the solution seems to have only a beneficial effect. The action of the solution upon dead bone can be readily demonstrated by placing a small portion of necrotic bone in it; the bone will in a short time begin to disintegrate and continue to do so until it is entirely divided into very minute particles.

In some of the cases of mastoiditis treated, in which the denuded surface was very extensive, in from three to six weeks the bone would be in a perfectly healthy condition, the discharge of pus controlled, and the subsequent closing of the wound, when allowed, occurred rapidly and was perfectly satisfactory.

In one of the cases, in which for three years any attempt to allow the closing of the sinuses would be followed by an exacerbation of the inflammation, the carious condition was relieved and the opening allowed to close after two months of treatment.

The treatment is very simple and consists in syringing through the opening and into the meatus with a small glass syringe a sufficient quantity of the fifteen volume solution, at each sitting, to render the pus thoroughly aseptic, then packing the ear and the wound lightly with strips of sheet lint or gauze *thoroughly soaked in the same solution, great care* being taken to allow the wound to close, although the packing must not be so introduced that it will prevent the free exit of any pus which may be formed during the interval between the dressings. The external incision should be made ample and if the packing does not prevent the opening from closing during the progress of the treatment it must be reopened with the knife. Glycozone has been suggested for use in keeping the wound open, being used instead of the peroxide in the dressing.

The result of this line of treatment which has been followed in a considerable number of mastoid cases, has indicated the possibility of a degree of conservatism in the treatment of mastoid disease which is very desirable.

All the cases treated have done well, no deaths have occurred and in no case was it considered necessary to scrape the bone or to remove any portion of it, while the period of time necessary for the wound to assume a sufficiently healthy condition to render it advisable to permit it to close, did not seem longer than the time which must ordinarily elapse after the operation for thoroughly scraping the mastoid, and was much shorter than the time required before the wound produced in chiseling the mastoid could possibly be allowed to close.

Special care should be taken to keep all the applicators or sprays, used either with the peroxide of hydrogen solution or glycozone, perfectly clean, especially in case of mixtures of glycerine and peroxide which should be made fresh every second or third day to prevent the possible formation of formic acid; only silver, hard rubber, glass or porcelain should be used for measuring purposes.

If care is taken to properly keep the solutions, they are perfectly harmless and calculated to be of inestimable benefit to all who use them.

NASO-PHARYNGEAL LESIONS DUE TO CENTRAL VASO-MOTOR CAUSES.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY RALPH W. SEISS, M.D.,
OF PHILADELPHIA, PA.

It has long been known by laryngologists that various lesions of the naso-pharynx are *essentially* nervous diseases, dependent on central causes, but the literature of the subject is not extensive, nor do any very definite conclusions appear to have been expressed.

The naso-pharyngeal diseases which I will consider as being due mainly to cerebral causes, are certain forms of "nervous coryza," including some types of obstructive enlargement of the turbinated tissues; recurrent engorgement of the lateral pharyngeal walls not dependent on inflammatory causes; and various forms of pharyngeal and lingual varix, especially of the base of the tongue. All of these diseased conditions may be classed among the *angio-neuroses*, and appear to be due either to some mal-condition of the vaso-motor centre in the medulla oblongata, or to truly cerebral conditions.

"Nervous coryza" in its various phases, all of which more or less resemble attacks of typical hay fever, has an extensive literature, and has been studied in much detail. That the seizures may be due to purely mental factors, such as anxiety, fright or anger, is, however, not very often noted, though of frequent occurrence. Some of the most typical cases I have seen have followed nervous breakdowns from excessive brain work or worry, and all have occurred in so-called neurotic individuals with irritable hearts and tired-out nervous systems. The relations of the conditions named to "rhinitis sympathetica" was pointed out by J. N. Mackenzie, in 1885, and has since been noted by many rhinologists. The association of the nasal condition with very marked *general* vaso-motor neuroses in all cases has not, however, been brought into much prominence. Almost invariably patients with "nervous coryza" complain of troublesome cardiac action, profuse perspiration on slight exertion, sensations of numbness, etc., in the limbs, cold extremities, headache and "nervousness."

The results of inspection are only conclusive when considered along with the general history; a constant condition, however, is *intermittent* distention of the vascular sinuses, generally very marked, and the swelling being accompanied by but slight superficial changes or inflammatory redness.

Passive congestion of the vascular areas about the palatine arches has been recognized frequently to be a pathological condition not caused by any of the usual factors of inflammatory states, and the resulting discomfort as most difficult to relieve by local treatment. Angio-neuroses of the pharynx may occur in cases of rhinitis sympathetica, or of lingual varix, or may be found alone. The attack may come on suddenly, following physical or more especially, mental overexertion or emotional excitement, or the condition may persist and become chronic. The symptoms are local "throat-fretting," as I have called the various sensations described by patients, particularly a feeling of local fatigue and weakness, and in some cases, a burning sensation quite unlike that of any form of inflammatory sore throat. Constitutionally the patient presents the usual characters of nerve weakness and low blood-vessel tone, and is usually decidedly emotional and neurotic. The appearances on inspection are those of great vascular relaxation, and large, varicose vessels may traverse the half arches; the ordinary lesions of chronic pharyngitis may also be present in varying degree. The conditions are very transient, and may subside in a few hours, or may persist without intermission, although great variability is characteristic of the disease.

Varix of the lingual tonsil and epiglottis has been written upon by many observers, and its occurrence with general vaso-motor neurosis noted; but its association with grave *central* lesions has not been emphasized, though Dickson regards it of diagnostic importance in brain and heart lesions. The clinical history of such cases is much the same as that of the other angio-neuroses mentioned, the whole vascular and nervous systems being usually much below par. The local symptoms may include marked paroxysmal dyspnœa, which, as in a case lately under my observation, may threaten life, and the hydra-headed sensations grouped under the name paræsthesia.

Examination with the laryngeal mirror shows the well known gorged, tortuous veins, blue or purple in color, radiating from the lingual tonsil over the base of the tongue, the lingual surface of the epiglottis, and the lateral pharyngeal walls. Advanced changes in the whole upper respiratory tract are also decidedly the rule in these cases.

The following brief history of cases illustrates the various types of angio-neuroses of the upper respiratory tract.

Case 1.—Mr. M., music teacher, 25 years of age; belongs to a neurotic family, but claims to have been well until lately. Has marked cardiac irritability, sleeplessness and much local discomfort in the throat and nose, coming on only when *fatigued*, and consisting of pain, hoarseness and dryness. Examination showed great vascularity of the lateral pharyngeal areas; a tortuous vein larger than a match stick traversing the posterior half arch of both sides. The lingual tonsil was enlarged, its vessels dilated, and the larynx somewhat hyperæmic. Treatment consisted of rest, strychnine and coca wine internally, and sedative sprays and pigments locally. Complete relief resulted, lasting for more than a year, but a relapse has lately occurred, and the patient is now absent in Europe.

Case 2.—Miss A., 31 years old. Has had thyroid goitre for 9 years, lately has had cardiac palpitation, tinnitus aurium and "risings" and discomfort in throat, and impairment of general health. The turbinated bodies at two subsequent daily visits showed complete contraction, as if cocainized, and equally complete stenosis of the nares from relaxation; this was repeatedly observed. The lingual fossa contained numerous varicose vessels pushing the epiglottis so far backward as to hinder laryngoscopy. Rest and tonics were ordered and systematic faradization begun, but the patient discontinued her visits as soon as slight relief occurred, and the ultimate result of treatment cannot be given.

Case 3.—Miss M., professional nurse, about 26 years of age. Has always been vigorous and healthy until last few months, having worked at her profession without holiday for four years. Now complains of numbness and other paræsthesias in limbs, heart pain and tachycardia, sore throat and cough of a short, irritative character. Examination showed an irritative rhinitis, of typical vaso-motor or "hay-fever" type, and engorgement of the lateral pharyngeal and lingual areas. Treatment consisted of a month's perfect rest in the country, bromides for sleeplessness, tonics, general faradization and sedative local applications. Complete relief resulted in about two months, and continued through a winter of very hard work, but ceaseless care with a dying cancer patient has recently brought about a perfectly typical relapse, with constant irritative cough and much pain over the cardiac region.

In addition to the more typical angio-neuroses of the upper respiratory tract, central nervous causes bear an important part in the etiology of diseases of the naso-larynx. It is a fact in the experience of the writer and his colleagues that, outside of syphilitic patients, worse cases of irritative rhino-laryngitis are seen in private practice and among the mentally and emotionally over-worked, than in dispensary service, and the writer has for years regarded the "catarrhal tendency" and "neurasthenia" as practically synonymous; especially is this shown in cases of naso-pharyngeal and aural sclerosis, such patients almost invariably having very poor circulations and irritable cerebral centres. The association of pharyngeal varix with enlargement of the *thyroid gland*, as in the case cited above, is not at all rare in females, and was noted by Lennox Browne some years ago. Varicose veins in other regions of the body have also been frequently noted, and are "concomitant evidences of the dyscrasia."

The results of persistent vascular distention from central causes are, according to pathologists: 1. Increased *vulnerability* of the area affected, a slight irritant causing inflammation. 2. Hypertrophy of the tissues in some cases. 3. Fibroid changes or induration, followed by atrophy. Bearing these consequences in mind, the local changes in very many cases of throat and nose disease are logically explained. The great tendency of such patients to suffer from acute inflammatory attacks, the hypertrophic changes which occur, and the sclerotic and atrophic lesions which are characteristic of advanced catarrhal cases, are all accounted for. Accepting the fact that many cases of "catarrh" are due solely to disease of the vaso-motor centres, the total failure of local treatment in numerous instances is also satisfactorily explained.

Leaving the attractive study of the nerve paths by which neuro-paralytic or neurotonic hyperæmia is produced, the important subject of treatment demands attention. All laryngologists, who are also comparative pathologists, must have been struck by the great rarity of *chronic* rhino-laryngitis in the lower animals, many of which are subjected to the same conditions of environment as their catarrh tormented lords. The writer believes that the most important reason for this state of things is the non-neurotic and well-controlled vaso-motor centres of the lower mammals; blushing, Reynaud's disease, *non-inflammatory* varices are conditions yet to be reported, I believe, by veterinary pathologists. It is, therefore, evident that treatment should be largely devoted, in these cases, to the nervous system to secure the best results. The therapeutic measures of most value are well chosen climatic changes, rest, systematic outdoor exercise, regulated bathings, frictions, and massage. General faradization has a very happy effect in many cases, and is always employed by the writer, a weak current being generally used. Drugs are less satisfactory, but strychnine, perhaps best given by hypodermic injection, and the bromides frequently act well, and tonics are, of course, always indicated. Medicines acting directly on the vaso-motor system, as camphoric acid, atropine and digitalis, are sometimes indicated, and many cases will need the approved treatment of tachycardia in detail. Local treatment has at least a palliative action, and may also operate by transmitting favorable influences to the medulla, since it is well known that an irritation may thus be transmitted and reflected back upon the vaso-motor nerves. On the other hand badly chosen local therapeutics, acting as an irritant, is quite certain to operate injuriously on the vascular centres and increase the original disease. Especially may ill-timed operations, as the writer has again and again seen, act as nerve depressants and seriously exaggerate both the local disease and the general neurosis. It is my habit to treat cases of undoubted angio-neurosis with the utmost conservatism, using only the mildest applications and methods, and depending at least as much on hygienic and constitutional measures, as on local treatment. Energetic operative procedures are in a few instances, however, absolutely necessary, as shown by the following case:

Lawrence A., aged 13 years; a typically neurotic and emotional boy, suffering from nervous headaches, excessive sweating, enuresis nocturna and mental disturbances amounting almost to hallucinations. The nares were blocked from end to end with vascular enlargements, completely contractile under cocaine, and at rare intervals disappearing almost entirely of their own accord. Tonics, exercise and the strict routine of a large school brought about much improvement, but the occasional stenosis was so annoying that operative measures were advised. I used the galvano-cautery, chromic acid and the Jarvis snare, in turn, at intervals extending over a year, and finally secured a satisfactory breathing space, the amount of vascular tissue removed or tacked down on either side being certainly as large in bulk as the little finger, the capillaries seeming to dilate almost as fast as the paretic sinuses were removed. Although the final result has been fairly satisfactory, there is no doubt in my mind that each operation was *per se* an irritant to the vaso-motor centres, and to a degree added to the diseased condition. I should not have employed such energetic measures had the patient been an adult, or if general improvement had not first resulted.

Of special drugs locally useful in angio-neurotic cases, benzoate of sodium (10 to 20 grains per ounce of water), used as a spray, is specially sedative and valuable as a throat application. Menthol (10 to 30 grains per ounce of alcohol and glycerine) has also a most beneficial effect in the same class of cases, when used as a pigment applied directly to the areas of paræsthesia. The volatile oils of sassafras and cinnamon, menthol, thymol and camphor are valuable medicines in spray form for nasal applications; they may be variously combined, and used in either aqueous solution or dissolved in one of the bland petroleum oils. Any of the standard sprays or pigments may be indicated in a given case since the ordinary inflammatory lesions of the naso-pharynx may occur and require treatment in a typically "central" case, and it is especially important that the whole nasal-bronchial mucous membrane be put in as healthy condition as possible. Future observations will, doubtless, at an early date more clearly outline the etiology of pharyngeal neuroses and discover more rational methods of cure; but the writer cannot believe that these will consist of local destruction of tissue, or will be accomplished by a new cauterizing agent or an electric saw. At present scientific treatment would seem to include all measures recognized as general or local nerve tonics, and to rigorously debar all irritants, depressants and abnormal vaso-motor excitants; and in direct relation to the constitutional good effects of such treatment, will be the improvement in the local angio-neuroses.

Discussion.

Dr. Dowling, of Cincinnati, said:—I was very much interested in the able and very ingenious paper of Dr. Seiss, of Philadelphia. I am sorry I am not sufficiently well acquainted with the subject, to discuss it as intelligently as it has been presented. I think that the internal administration of strychnine and arsenic with extract of hyascyamin, does a great deal of good, owing to their sedative and tonic influences on the nerve centers. I have derived excellent results from this treatment in sympathetic affections of the mucous membrane of the eyes. caused by congestion of the nasal mucous membrane, owing to disease of that covering. In addition to this I would recommend salt water baths as an adjunct.

Dr. Price Brown remarked:—In the hyperæsthesia of nasal mucous membrane I have found. particularly in hay fever, that treating certain spots, particularly portions of inferior turbinate and a spot situated between the middle and inferior turbinates anteriorly, also a spot almost opposite the last mentioned, as the septum, with galvano-cautery has been followed with best results.

Dr. Thrasher said that while in the main he perfectly agreed with the author, yet in some minor particulars he must differ. In cases of obstruction of naris he often found the deep antero-posterior cautery act well, binding down the bulging mucosa to the bony structures by cicatricial adhesive bands. The varicose lingual base he had rarely associated with neurotic diseases, and he would rather consider the connection accidental than causal. He thought that the lower animals had been not sufficiently well observed as it was quite well known that many monkeys, birds, etc., blushed or exhibited analogous phenomena.

Dr. Hubbard, of Toledo:—I want to add my testimony to the statement by Dr. Seiss that the use of astringents and galvano-cautery are, as a rule, to be avoided in cases of pure vaso-motor catarrhal conditions. His treatment as outlined is excellent, and I have supplemented it with a special apparatus for securing the effect of heat and cold within the nasal cavity. A small, soft rubber bag about the size of the small finger of a glove is slipped over the end of a soft catheter and secured by winding thread around the open end of the bag and catheter. There should be a small stopcock or cut-off between the catheter and syringe. Insert this dilator gently (having first used a solution of menthol in al. vas.) and then inflate with hot and cold water alternately by means of the syringe. Allow each to remain in contact a minute or so. This method is not applicable where there is a bony obstruction to the canal except after operation. This is a very useful apparatus in epistaxis where the source of hæmorrhage is beyond the reach of the cautery, and it is a very proper substitute for the barbarous old-fashioned post-nasal plugging apparatus.

Dr. Seiss regards laryngeal and nasal disease as *the* cause of laryngismus stridulus, and local treatment as the first indication. Thinks cocaine injurious in all vaso-motor cases. Admitted the blushing of certain birds and monkeys, but spoke only of the ordinary domestic mammals. Thinks the local use of hot and cold, as mentioned by Dr. Hubbard, as very valuable.

TONSILLITIS AS AN INITIAL SYMPTOM OF ACUTE RHEUMATISM IN THE ADULT.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892

BY JEFFERSON C. CROSSLAND, A.M., M.D.,
OF ZANESVILLE, OHIO.

In attempting to present this subject, I am actuated not especially by the novelty of the subject, which nevertheless I am compelled to believe is far less common than some writers would have us believe, but by the uniqueness of the case, the history of which is herein given, and a desire to direct attention to the two important subjects of diagnosis and treatment. It is well-known that tonsillitis not infrequently occurs during an attack of rheumatism, especially in persons of scrofulous and rheumatic diatheses; but it is only as an introductory symptom that it requires diagnostic skill, and becomes of importance in determining the character of treatment. I now wish to give the history of a succession of cases in the same individual. In giving the history of these attacks, I shall give it in the order in which the attacks occurred. I treated the patient in the last attack only. The history of former attacks was obtained from the patient. The patient is now thirty years of age. At the age of seventeen, he had an attack of non-suppurative tonsillitis. The duration of this attack of angina was about two weeks. It was immediately followed by acute articular rheumatism of two week's duration. At twenty years of age the patient had an attack of suppurative tonsillitis which lasted two weeks. Acute articular rheumatism again promptly followed the tonsillitis. This attack of rheumatism was very severe, protracted, and general. At twenty-nine years of age, the patient experienced a third and severe attack of suppurative tonsillitis which lasted four weeks. This attack of tonsillitis, as in previous instances, was followed by rheumatism which was severe, general and of five month's duration. At the age of thirty, and in February of this year, the patient had his fourth attack of suppurative tonsillitis which lasted about one week. This attack as usual with this patient, was followed by other symptoms of inflammatory rheumatism. This attack of rheumatism was pretty general, many of the joints being more or less affected. The duration of the attack, however, was comparatively short. The patient was confined to the bed one week, and to the house two weeks. There was not complete recovery, however, for several weeks, which I attribute to the patient resuming work too soon.

A few observations on this recurring series of diseases may be of interest. The individual is a strong young man. His occupation has been varied. At the time of his first attack, he was a laborer in a rolling mill. For the last year, he has been engaged in the insurance business, doing office work. He did not inherit a rheumatic or scrofulous diathesis. Neither did he inherit any predisposition to throat affections.

He cannot in any instance recall any exciting cause, such as exposure to cold and damp. He has never had tonsillitis without rheumatism following it. He has never had rheumatism without tonsillitis immediately preceding it. The tonsillitis has been suppurative in the last three attacks. The duration and severity of the attacks of rheumatism have been in proportion to the duration and severity of the attacks of tonsillitis. In no attack has there been any subjective symptoms of rheumatism prior to the subsidence of the tonsillitis. Neither were there any objective symptoms aside from those characteristic of the tonsillitis. In the first attack, there was a mild throat affection, and a light and short attack of rheumatism. In the succeeding two instances both the tonsillitis and rheumatism were severe and prolonged. In the last attack, both diseases were moderately severe but of brief duration. I desire now to call your attention to the case in a diagnostic and therapeutic point of view. Ability to recognize the exact character of the tonsillitis, is especially desirable, for it would impress the patient with the physician's keen and far-reaching insight into his disease and also afford him an opportunity to try abortive treatment. When called to treat the patient for tonsillitis, he asked me to give him also preventive treatment for rheumatism, saying that rheumatism would develop as soon as recovery from tonsillitis had been accomplished, and justified his prediction by his experience. The patient made the diagnosis and I had only to confirm it. The disease was of two or three days' standing, the patient having come from a neighboring town. There was a feeling of dulness and languor for two or three days preceding the attack. Patient's attention was next attracted by pain which accompanied the act of swallowing. Constitutional and local symptoms followed. Other points of differentiation were the more general, inflammation, hyperæsthesia and swelling of the peritonsillar tissues and structures of the neck, pain more diffused on the side on which the tonsil was inflamed, and the very rapid shifting of the disease, and pain from one tonsil to the other. The acceleration of the pulse and the elevation of temperature, which ranged from 101° to 103°, were less marked than ordinarily obtains in idiopathic tonsillitis of equal severity. At this juncture, and before speaking of treatment, I will merely allude to the etiology of rheumatism without any attempt to discuss the various theories for it. Whether the causative agent is developed within the body or enters it from without in this, the germ era of medicine, with the history of the above and similar cases in mind, one can but feel a great deal of assurance in assuming that the causative agent is a germ or substance which enters the body through the crypts of the tonsils, lodging there and producing inflammation, or, if entering the body elsewhere or developing within, that the disease substance collects in or concentrates its force on the tonsillar tissues. With this view of etiology in the above case it would appear that proper local treatment would be fully as important as constitutional treatment. Therefore in the above case, I determined to abridge the course of the tonsillitis, hoping thereby to modify the course of the rheumatism. In what measure I succeeded may be fairly judged by the result already mentioned.

Treatment consisted mainly of free and repeated lancing of the tonsils with the use of warm water to promote bleeding. Anodyne and antiseptic sprays, prompt and complete evacuation of pus, which formed in one tonsil only, with saline cathartics and mild anti-rheumatic treatment. I learned from the patient that depletion had not been practiced in his former attacks and the abscesses were allowed to open spontaneously. We cannot wonder then at the prolonged and severe attacks of rheumatism that followed.

In view of foregoing facts I am compelled to believe that in cases of rheumatism in which parenchymatous tonsillitis is an antecedent symptom, the disease is at that stage largely local and affording exit for the disease germs and their morbid products by free depletion, and early evacuation of pus when there is suppuration will aid marvellously in abridging and mitigating the subsequent attack of rheumatism, if not entirely prevent it.

SOME CHARACTERISTICS DISPLAYED BY THE HUMAN MIND WHEN PLACED AT A DISADVANTAGE—A PSYCHOLOGICAL STUDY.

Read before the Section of Neurology and Medical Jurisprudence at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY T. L. WRIGHT, M.D.,
OF BELLEFONTAINE, OHIO.

When the traveller in the dusty and parched desert, views the mirage afar off, promising water to his burning lips, and the cool shade of green trees to his heated and weary frame, he hastens his pace, that he may the more speedily enjoy the refreshment and repose that seem to be almost within his grasp. But as he journeys onward, the pleasing vision recedes; it slowly fades—it disappears. Yet, how real, how true it seemed! Had some accident turned the beholder from his path, and he had failed to detect the illusion, his convictions would ever have remained true to the idea, that the phantom picture was a veritable reality. Indeed, thoughts and convictions, and conduct legitimately derived from a belief in the material certainty of the scene—though erroneous and possibly criminal—could by no fair rule be imputed to him as an agent truly responsible.

To illustrate the mystic snare in the meshes of which the mind may be entangled, and held prisoner—when no opportunity is presented to test and verify the *seeming*, by comparison with the substantial and *material*—the pretty fable of the imprisonment of Merlin, the necromancer, is quite in point.

The "Lady of the Lake"—called also the Fair Viviane—was enamored of Merlin, as indeed he also was of her. Casting about for some way by which she might detain him "for evermore," she persuaded him to impart to her, some of the secrets of his art. "At length it fell out, as they were going one day, hand in hand through a forest, they found a bush of white thorn. They seated themselves under the shade of this bush upon the grass, and Merlin fell asleep. Then the dame rose and made a ring with her wimple round the bush, and round Merlin, and began her enchantments, such as he himself had taught her; and nine times she made the ring, and nine times she made the enchantment, and then she went and sat down by him. And when he awoke, it seemed to him that he was enclosed in the strongest tower in the world, and laid upon a fair bed. Then he said to the dame, 'you have deceived me unless you abide with me, for no one hath power to unmake this tower but you alone.' And Merlin never went out of that tower where his mistress, Viviane, had enclosed him; but she entered and went out again as she listed."

In order to obtain his freedom, all that Merlin had to do was to make the effort and walk out of the seeming prison. But the illusion was so vivid and truth-like, that the mind was servilely submissive to the delusive yoke placed upon it. Thoughts, convictions and acts, based upon such a condition of hypnotic trance, could not, by any reasonable consideration, be held as proper subjects of accountability.

There are other sources of delusion, it is perhaps superfluous to say, besides the apparent freaks in nature's laws exterior to the physical organism, and besides the weakness and unsteadiness of the nervous energies within it.

Diseases within the brain not infrequently affect one or more of the senses in a manner analogous to the impressions received through normal avenues. The mind is ignorant of the source of sensations thus originating; and they are, as a rule, wrongly interpreted. Yet the will directs the personal conduct in a way that would accord with the healthful operations of the perceptive faculties. So convincing are morbid hallucinations, that the mind is prone to receive them as representatives of the material forces of surrounding nature; and its movements are most likely in a line with their false and delusive teachings. It is evident that responsibility, for acts growing directly from the impulses of hallucination, should not be esteemed as complete. Hallucinations, as well as epilepsy, and other nerve and mind disabilities, may come from *traumatism*, as well as from brain disease. Injuries, though distant from the great nerve centers (not to mention the presence of foreign bodies in the physical organism), may produce such morbid nervous impressions as will simulate disease of the brain itself.

It is moreover true, that while the nervous system is in a morbidly receptive and impressible state, some very striking movement of the perceptive faculties may become aroused. A time may come when the system of nerves may again occupy a similar or identical position. In such an event, there is liable to occur a *suggestion*, which will bring to mind that same vivid perception that had been once before associated with the pending and peculiar nervous state. In this way, many strange and incongruous fancies may be generated. Dreams, somnambulism, trances—with their disconnected phantoms, their images awry and half fashioned, and their procession of ever changing shadows, and airy, though fearful nothings, have such birth as this. Here too, is total absence of sound sense and reason, although the will itself may be compelled to enter into the service of this farrago of nonsense. Under such conditions of misapprehension it is clear there is absence of moral and mental responsibility.

It is probable that few persons if any, are exempt from the trickery and deceit which are liable to be imposed upon the human mind by concealed agencies. The best poised and calmest intellects have, no doubt, their brief seasons of illusion, of hallucination, and of dangerous delusive beliefs. The deed is done. The irrevocable word is spoken. Whence comes the impulse of which it is the outcome? "I can give no reason. It is an impenetrable mystery to me!" This is the exclamation heard very often indeed, in that period of time called—"too late"—a period fully within the possibilities of every man living.

Let us now turn to another phase of our subject, and examine some of the characteristics of the human mind when placed at a disadvantage through the influence of toxic agents. We are at once struck with several particulars that have not appeared in our observations hitherto. We have been describing the senses when, to a considerable degree, they were deceived in their individual capacity. We are about to speak of the senses overwhelmed *en masse*. We have been noting defects that were mostly circumscribed in their range and application, that in fact, preserved to themselves some small quality of system and order. We are about to speak of mental confusion, incoherence, wreck. We have been treating of simple intellectual *incompleteness*, the causes of which have been mainly exterior to the bodily organism, and occurring without the complicity of the mind itself. We now proceed to examine the *total dissolution* of the mental and moral natures, brought on (as some declare) by the deliberate and wilful act of the victim himself.

In this work I will confine my thoughts to the alcoholic inebriate. I will speak of facts and principles in their general aspects, taking no account of the many exceptions and cavils that invariably beset comprehensive propositions.

In the family of man, there is a large number of individuals who live habitually under the control of a nervous system of exceeding and abnormal sensitiveness. Impressions are absolutely startling in their intensity; and the mind seems continually to be waiting in painful suspense, lest some new and unwelcome sensation should suddenly present itself. Perceptions, instead of leading to rational and practical knowledge, appear to palpitate throughout the whole mental and moral being, and arouse by an irrational but boundless sympathy, unexpected and undesirable associations. To the neurotic, the future is clothed very often, in impenetrable darkness, and is filled with possibilities of hopeless woe; and of these his fancy is incessantly seizing upon some, which he holds to his heart as realities.

In a very wide sense,feeling is living; and feeling, in the neurotic, is a pitiless and unceasing torture. A man finding himself in the midst of fire will jump out of it; and little will he reck which way he leaps, or what may be the consequences to himself or to others. Considerations as to that matter do not enter into his motives in avoiding the flames. Casuists may dispute as to the quality of will, involved in the case. Certain it is, that such an escape is not in obedience to free will, to will invested with the capacity of choice. It is merely an example of the instinct or impulse of self preservation, which is common to the nature of all animated beings.

In a manner analogous, when a mind is chafing under the oppression and tyranny of an universal nervous irritation, it will be compelled, sooner or later to seek some measure of relief; and that too, without much consideration as to the means it may be called upon to employ. It is wholly immaterial to one suffering in a prolonged nervous agony, whether, " being sane he knows the effects of alcohol on him, and therefore, he is responsible for them," or not. The legal apothegm does not cover all the material points involved. Like one in the midst of a sea of fire, the inebriate has became frantic for relief. He does not drink to create effects, he drinks to destroy effects. He knows that alcohol will afford rest from his consuming nervous inquietude; and he appeals to it as the one available instant refuge.

An immediate effect of alcohol upon the human body is the production of partial paralysis. While this appears to extend throughout the entire system, it also seems to vary somewhat in its intensity as it affects different portions of the organism. For the alcoholic impression as a whole, does not depress or hinder the bodily functions equally. Judging from the tumultuous but discordant movements that attend physical and mental activity while under the influence of alcohol, the inference is, that this incoherence results from irregularity in the power exerted by that agent, over the several departments of the corporal structure.

Alcohol is a speedy and reliable anæsthetic. By it, the morbid sensitiveness of the neurotic constitution is allayed. Sensation is blunted; perception is proportionally dulled, and they cease to worry and distress the mind and nerves. A welcome repose comes where but a little time before, there were doubts, fears and painful anticipations.

Another alluring element of rest to the perturbed mind of the neurotic. is the influence that anæsthesia exercises upon the faculty of attention. Everybody knows how tiresome it is to hold the attention firmly in a given direction, when the nervous system is in a state of prostration. When convalescing after serious illness, it is common to lose one's self in the midst of some brief narrative, and inquire with a sigh of fatigue—" where was I, what was I talking about?" The dullness of the perceptive faculties induced by anæsthesia, separates the mind in a notable degree, from the world surrounding it. The association between the material and immaterial is interrupted; and the mind like a ship without rudder or compass floats away on the shoreless sea of an uncurbed imagination.

This leads to the consideration of another one of the primary effects of alcohol upon the mind; and it is the immediate result of blunting the sensibilities and the perceptive faculties by means of anæsthesia. The authority of *attention* having been withdrawn from the world of thought and feeling, the mind wanders free and untrammeled. No longer occupied with the affairs of present and practical life, the imagination seizes upon the stores of memory, upon the suggestions of the organic processes within the body, and even upon the unsubstantial fancies of dreams and reveries past and gone. Of these it constructs phantoms and combinations and contrasts, absurd, brilliant, or trifling, as the case may happen. In truth, the inebriate mind is in a state very similar to the one occupied in trances, visions and somnambulism—of which, brief note has already been taken. The mind works subjectively—within itself exclusively. Illusions, hallucinations, and delusive beliefs, framed from the odds and ends, the *debris* of the past in thought and feeling, delight the roving and ethereal fancy.

And here a brief suggestion or two may be not unprofitable. The inconstant and elusive state of mind just described, is commonly attributed to the stimulating effects of alcohol.

(*a*) Alcohol appears to act as an excitant upon the heart and brain. This is, however, to some extent, deceptive. Alcohol is a poison; and when taken in considerable quantity, the whole organism is thrown into a tumult of action in the endeavor to rid itself of the dangerous intruder. The system is invariably prostrated when this work is done—showing that the extra work was at the expense of the system itself mainly, and not by the aid of allies or auxiliaries.

(*b*) The destruction of the sensibilities also operates as a pseudo-stimulant, by setting free, through anæsthesia, the body and mind, from irksome and laborious association with the material surroundings.

(*c*) Again, alcohol acts as a *quasi* stimulant by the seeming contradiction of its benumbing powers. In other words, alcohol paralyzes with peculiar emphasis, certain *restrictive*, or inhibitory nerve centers. It interferes with the monitors, the regulators of the imagination, and permits that faculty to roam without law or restraint.

These three primary or instant effects of alcohol, are they which prove so alluring to the inebriate. The neurotic partakes of alcohol with the object of obtaining the quickest and best relief from a great nervous agony or strain. The primary effects of alcohol fulfill the measure of this object perfectly. The point is to secure the instantaneous application of the first impressions made by the alcoholic agent. The motives actuating the inebriate, do not therefore reach to the secondary stages of drunkenness; nor, still less, to the last or tertiary stages.

In concluding what I have to say about the condition and responsibility of mind, when it is placed at disadvantage by alcohol, I will simply add this: There are certain lines that are common to alcoholic intoxication in all circumstances. But it is important to remember that psychologically, the mental and moral situations are radically different, in the several conditions of the inebriate constitution. In the primary stage of inebriety in a sound constitution, the imagination is vivid and bright (though erratic) and good fellowship reigns. In the secondary stage, the circulating fluid is filled with poisons other than alcoholic; the whole organism is in a quiver of anguish, while the mind is sullen, morose, hateful. In the third stage, when the brain, heart and glandular system have undergone profound physical degeneration, the mind is imbecile and degraded, but is comparatively harmless.

In conclusion, I will call attention to the fact, that intoxication is not the only bad outcome of the alcoholic influence; and also that it is not the result always the most to be deplored. Recent intoxication is supposed to be rather agreeable than otherwise. It excites the generous and sympathetic feelings. But when drunkenness is complicated by the presence, within the organism of subsidiary poisons contingent upon the prolonged use of alcohol, the spectacle is quite different. There are toxic principles in alcohol which are more destructive than those producing the state of simple inebriation. They are the fruitful sources of physical degenerations, both of the body at large and of the brain in particular, that are seldom the consequences of intoxication from opium, chloral, haschisch and other hypnotics. Indeed, alcohol is capable of producing all the degenerative injuries peculiar to the habitual inebriate *without* ever proceeding to the point of actual drunkenness. Dr. Maudsley expressly mentions "that more dangerous form of habitual indulgence in small quantities of wine and spirits throughout the day by which some active men of business endeavor to spur their overtaxed energies." To these poisonous properties of alcohol (which belong to few other intoxicants) the attention of the public should be directed. In that way only, can the true gravity of carelessly and ignorantly handling that most powerful but most pernicious agent, alcohol, become fully appreciated.

EUCALYPTOL IN DIPHTHERIA.

Read in the Section of Laryngology and Otology at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY MARION THRASHER, M.D.,

OF SAN FRANCISCO, CAL.

A diphtheria epidemic pervaded portions of San-Francisco during the winter months of 1891–92. It was most plentiful and virulent in that part of the city, where there was a stagnation of sewage. The writer was located in that quarter, and had ample opportunity for the practical study of this much dreaded disease.

Years ago California imported the Australian gum tree, the *eucalyptus globulus*, for shade, it being a tree of rapid growth. The inhabitants soon learned that it absorbed malaria and transformed unhealthy into healthy localities. The writer observed in the above epidemic, that diphtheria was rarely if ever found in houses surrounded by eucalyptus trees.

Eucalyptol is a powerful germicide, a disinfectant, a stomachic, a tonic, a stimulant and antiperiodic.

In small doses it produces mental activity, accelerates circulation and respiration, excites salivary secretion, promotes appetite, induces diaphoresis, and increases the elimination of urea.

It is expelled from the system through the mucous membrane of the fauces, trachea, bronchi, skin and kidneys. In short it possesses all of the characteristics that a remedy should possess to meet the requirements of the pathological conditions found in a typical case of diphtheria.

In diphtheritic inflammation the exudation being not only upon but within the mucous structure, the therapeutic action of eucalyptol, seems clearly indicated. The Löffler-Klebs bacillus fastens not only upon the surface but beneath it, and an agent to be effective must destroy it wherever found, and at the same time produce no injury to the healthy tissue in and upon which it abounds. Eucalyptol fills that requirement.

Its tonic and stomachic power overcomes anorexia and places the stomach in a condition to digest nutritious food, and fortify the system against the general depression of the vital organs so characteristic of this disease.

Blood-poisoning is early indicated in the saffron skin, which may be counteracted, if not overcome, by the administration internally of eucalyptol, bichloride of mercury and quinine. Cardiac weakness should be anticipated, by giving from the outset a generous diet of milk and eggs, supplemented hourly with brandy and digitalis.

Ventilation should be looked after, and everything in the sick chamber should be kept disinfected and scrupulously clean.

The writer uses a 10 per cent. solution of eucalyptol in pure alcohol, and applies the solution locally to the diphtheritic exudation, hourly day and night. In addition he gives it internally every hour with quinine, iron and bichloride. Dr. Forcheimer, of Cincinnati, in a very able article in the International Clinic, first called the writer's attention to eucalyptol in the treatment of throat affections.

The writer has abandoned the use of trypsin, papayotin, and peroxide of hydrogen, as membrane solvents.

The etiology and pathology of diphtheria, a malady so appropriately named "the enemy of childhood," was but little understood until recently. The ignorance of the medical practitioner was such, that every step he took only increased the gravity of the prognosis.

The erroneous idea, that the diphtheritic membrane was but a fungous growth upon the throat surface, only to be removed by cauterization, was followed by disastrous results.

No physician was dextrous enough to swab the throat, and touch only the diseased part, much less the inexperienced nurse, to whom the task was usually assigned.

This operation would be difficult enough, were the patient an adult, which was seldom the case, but when it was a crying, squirming, fighting child, is it to be wondered at, that the lunar caustic made dozens of blistering patches on the hitherto healthy tissue, on which the false membrane would further spread?

Need we be astonished that under such misconception of pathology and treatment the disease produced such an alarming mortality?

The fatality is greater among the children from three to five years of age for no other reason than from the fact it is so difficult, at this early age, to practically medicate the throat.

The writer has in a measure overcome the difficulty by forcibly compelling the child to swallow semihourly the eucalyptol solution, which passing over the diseased tissue accomplished what is affected in older children with the swab or gargle.

Unlike most other remedies, should it come in contact with the adjoining healthy mucous membrane, as it undoubtedly will, it will give tonicity to the parts and in addition render them antiseptic, thus preventing the spread of the exudation.

In conclusion, while the writer does not claim that eucalyptol is a specific for diphtheria, yet he believes its general use in the disease will show a decided diminution in its mortality.

TREATMENT OF ASIATIC CHOLERA

BY INTRA-AREOLAR INJECTION OF LARGE VOLUMES OF WARM SALINE SOLUTIONS, AND AN ABUNDANT USE OF HOT ACIDULATED WATER, TO THE EXCLUSION OF ALL OTHER DRINKS.

Read before the Kansas City Academy of Medicine, October 1, 1892.

BY SIMEON S. TODD, M.D.,
Emeritus Professor of Obstetrics and Diseases of Women in the Kansas City Medical College.

Those of you who are readers of The Journal of the American Medical Association may remember a publication of mine in that journal, No. 6, Vol. iii, 1884, entitled "A New Method of Treating Asiatic Cholera Proposed." This was followed two years later by a paper upon the same subject, read in the Section of Practical Medicine at the thirty-seventh annual meeting of the American Medical Association, and printed in the same journal in July, 1886.

The plan of treatment urged in these papers, to be brief, was to maintain the normal volume, blood-pressure and integrity of the blood, as far as possible, and to sustain cardiac and vascular activity during that period when, other measures having failed, the blood-vessels are being rapidly drained of their serum. This was to be done by copious injections into the areolar spaces of an artificial serum, to which might be added alcohol, spirits of ammonia or other stimulants. In aid of this, and for the purpose of dilution, to impart heat to the stomach, and thus stimulate functional activity in the neighboring viscera through the semilunar ganglia and solar plexus; for its germicidal or other antidotal effect in the alimentary canal, for its local astringent effect and, incidentally, to allay thirst, I proposed the use as a drink of large quantities of water, hot as may be borne, pleasantly acidulated with sulphuric acid—the draught to be repeated instantly and as often as rejected, and even forced upon unwilling patients. Ice, and cold drinks of every kind, were to be absolutely and wholly interdicted. These were the two leading features of a line of practice that at the time of my first publication I believed to be wholly new, and these means I then believed and now believe to be most valuable auxiliaries to any plan of treatment that may be adopted.

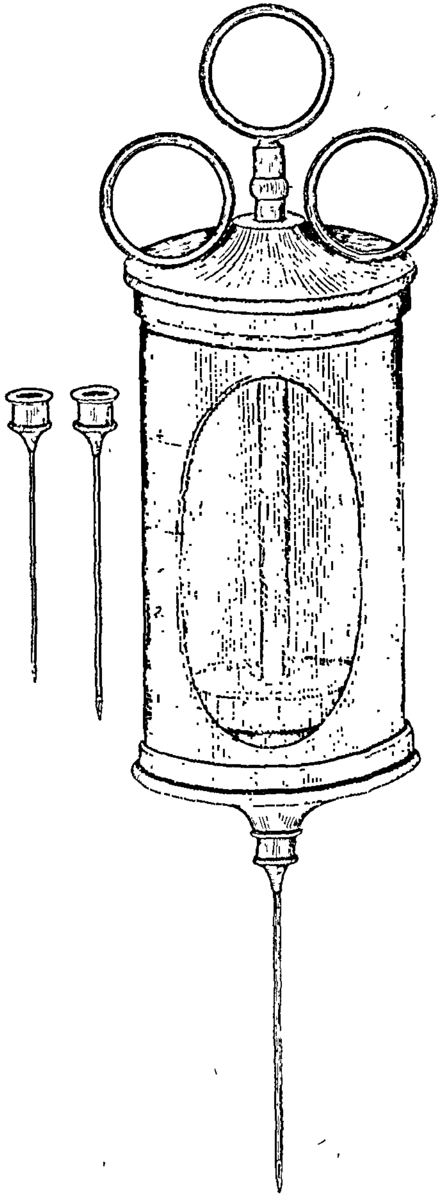
That the plan of treatment proposed by me was not wholly new I learned after the publication of my first paper, since it now appears from documents in my possession that as early as 1866 Dr. Cantani, of Venice, recommended "subcutaneous injections of *saline solutions*," and in the same year Dr. Beigel (*Lancet*, ii, pp. 352, 353) gives a case treated with hypodermic injections of warm water. The paper of Dr. Beigel was the report of a case of "complete collapse," in which hypodermic injections of "warm water to the extent in all, at first, of 7 ozs., were made into the calves, thighs and arms." As some benefit seemed to follow the measure, Dr. Beigel nade two further attempts, but the patient finally uccumbed. I need hardly say that not only was the uality of the fluid defective, as it was devoid of the aline constituents of the blood, but the quantity of luid injected in this case was too small to be of much ervice at any time, and absolutely useless in a case f "complete collapse." Dr. Cantani, as I did later, roposed to flood the circulatory system with saline olutions—"*injczioni sottocutanee di grandi quantita l'acqua salata tiepida.*" Again, in 1873, Prof. S. Samuel, of Königsberg, Prussia, published a paper n "Subcutaneous Infusion as a Method of Treating Cholera," in which he says that during an invasion f 1866 he "repeatedly injected substances into the calves and epigastrium." He does not name the 'substances" injected, but the inference is that drugs and the hypodermic syringe were used. His treatment, like that of Beigel, seems to have been without purpose, almost, and without value.

I did not expect to feel called upon to say anything further by way of introducing the proposed plan of treatment unless the disease should revisit this country. It is now lurking about our seashore, and no doubt with the return of warm weather will find its way to the interior by some one or more of the many avenues of entrance. Attempts at exclusion will fail, but measures of isolation and cleanliness, and personal prophylaxis, will limit the spread of the disease, lessen the number of those attacked and lower the death-rate, but will not hinder the epidemic from strewing its path with desolation and death, as former visitations abundantly show, if we are to rely solely on these safeguards and on former methods of treatment. For these reasons, and believing that the simple and rational suggestions of Cantani have not received ample trial, and that my own views as set forth in the two papers referred to, though gaining favorable comment in this country as well as abroad, have not received the attention they deserve, I am again impelled to affirm my continued and increased confidence in the proposed method of treatment, and again urge most earnestly the feasibility and reasonableness of these auxiliaries,and insist that they be given an early, hearty, vigorous and persistent trial in aid of whatever other means may be adopted.

One thing must not be forgotten if we would account for failure in the use of drugs. The pharynx, the œsophagus, the stomach and the intestines constitute the great route by which the poison of cholera enters the system. These organs are the first to feel the impact of the disease, and are chief among the sufferers. The changes in these structures begin early, and many times progress with wonderful rapidity—a rapidity proportioned to the quantity of poison finding entrance, perhaps, rather than the quality of the infecting matter, for we must suppose the *quality* of the morbific agent to be constant. The most deadly poison known, animal, vegetable or mineral, is absolutely harmless when greatly diluted.

What are the post-mortem findings? The venous side of the circulation is found in a state of intense engorgement, the vessels of the arterial system being comparatively empty. This engorgement of the veins is especially marked in the abdominal cavity, those which unite to form the portal vein and the portal vein itself being filled with dark, viscid blood. The urinary tract also suffers, but it is in the alimentary canal where the most destructive changes are wrought. The entire lining membrane is in a state of maceration. The pharynx, the œsophagus, the stomach, and small intestines especially, will be found denuded of patches of epithelium, and their villi exposed, or covered with mucus and partly detached fragments of epithelium.

These lessons from the dead-room show the danger of delay, and the utter futility of giving, by the stomach or rectum, drugs or fluids of any kind with the hope of having them absorbed, except in an early stage of the disease, or where but a small quantity of the poison has been taken into the stomach. Medicines by the stomach and rectum are alike rejected, or remaining, are not absorbed. As a consequence the discovery of hypodermic medication was hailed with much satisfaction as the epidemic of 1865–1866 made its approach, and the use of drugs by the hypodermic method and with the hypodermic syringe was everywhere resorted to, but with indifferent success, it must be said, except in mild cases and at an early stage of the disease, for the relief of pain. One obstacle stood in the way of success—the waste of the fluid part of the blood, with its salts, and the gradual clogging of the blood-vessels with the more solid parts of the blood, leading at the last to cessa-



tion of heart action for the want of the stimulus of repletion. All who have had experience with the disease will remember to have noted the wonderful outpouring of serum from the stomach, the bowels and the skin, as the disease approaches the algide stage.

The significance of these blood changes was early and duly appreciated, and when the visitation of 1831–1832 came about, some method of preserving fluidity of the blood had long been reckoned a desideratum. The practice of transfusion of blood had come into vogue, and from the transfusion of blood in a case of hæmorrhage to the transfusion of an artificial serum was a short step. From the year 1832, to and including the year 1873, sixty-eight papers on the subject of intravenous injections of saline solutions had been published, as shown by the laborious researches of Dr. John S. Billings, Asst. Surgeon U. S. A., in his report on the bibliography of cholera made in 1875 under the direction of the Surgeon-General of the Army, and published by Act of Congress. Of these thirty-seven, or more than one-half, were published as early as 1832. Many of these papers were reports of cases treated by this method. Some startling results were had in the hands of clever operators, even in cases of profound collapse, but the skill needed to make the injection with safety is such that the method will hardly ever meet with public favor. So cautious, indeed, were the physicians of our own country, and so doubtful of success, it may be, that two or three trials of the method only had been reported in the United States down to and including the epidemic of 1873.

Following on the heels of intravenous injection and the ushering in of hypodermic medication, the idea of intra-areolar injection of large quantities of an artificial serum was an easy and natural conception, and thus it was that in 1866 Cantani published his monograph on subcutaneous injections of warm saline water. The plan received little or no attention at the hands of the profession. He had no followers, strange as it may seem, save in the aimless and faltering manner of Dr. Beigel, and the suggestions of Dr. Cantani passed from memory. Down to the date of my first paper, in 1884, nothing further was heard of subcutaneous injection of warm saline solutions in great quantities for the purpose of replacing the wasted serum.

Here therapeutic measures rested at the time of my first publication. During the last epidemic, 1873, the means commonly employed hardly differed in the least from the means employed in 1832. Opiates, astringents, stimulants and the various acids were used in mild cases, and in the earliest stage of the disease in all cases. As the stage of collapse approached the quantity of stimulants by the stomach was increased, only to be rejected. Hypodermic injections of morphia, with alcohol or ammonia in some of its forms, friction, hot baths and other hot surroundings were resorted to with persistent purpose, but the feebleness of despair. During all of this period, with amazing incongruity, the patient was freely given ice and iced drinks to allay the implacable retchings and insatiate thirst. Intravenous injection of an artificial serum, the only measure that had given promise of success in collapse, was in the hands of the few—not used once perhaps in every one thousand cases. Subcutaneous injection with the purpose of replenishing the depleted blood-vessels seems never to have received a thought.

The universal and fatal error committed in allowing ice and iced drinks finds no rational explanation but in an apparent sense of hopelessness on the part of physicians and nurses, and the promptings of a humane desire to please the patient to the end. These things, so grateful to the patient, are craved in a most piteous manner, difficult to withstand, but certainly nothing can be conceived of in the way of drink more irrational or more deadly. And yet, in all of the voluminous cholera literature of the last sixty years, there has not come to us an authoritative remonstrance against the practice—not even a hint that the stomach, and that great nerve center in its neighborhood, the semilunar ganglia and solar plexus, need to be warmed into physiological activity with hot drinks rather than chilled into utter inaction with ice.

Then again, let it be remembered that from 1814 down to the present time, during the intervening epidemics and covering a vast field of observation, the prophylactic and therapeutic value of the acids, and especially the sulphuric acid, had again and again been demonstrated beyond question, and yet it has never once been authoritatively suggested, from the date mentioned down to the present time, that copious draughts of hot water pleasantly acidulated with sulphuric acid should wholly supplant the use of ice and cold drinks. That it should be necessary to press upon the attention of the profession so earnestly the measure of introducing into the areolar tissues large volumes of artificial serum at a time when the absorbents are still active, and at a yet earlier period warm the rapidly cooling stomach with hot acidulated water—means so simple, so available and so rational, is a matter of no little wonder. So simple and self-suggestive are these means that it may happen that I shall be met with a denial of their novelty, but the facts are as indisputable as they are remarkable.

It must be noted that in all cases of much severity that concurrent with the destructive changes taking place in the alimentary canal, the vaso-motor nerves of the parts supplied by the solar plexus and the abdominal branch of the right pneumogastric suffer a paresis. From the open mouths of the capillaries are poured forth torrents of serum. The current is toward the mucous surface of the stomach and intestines, and as before stated, there can be no absorption from the alimentary canal when this outpouring has been set up. If then there has been failure to arrest the disease at an earlier period with the use of dilute sulphuric acid, opiates and stimulating astringents, and vomiting and purging continue, with thirst, the stomach and entire alimentary canal, if possible, should be flooded with draughts of water pleasantly acidulated with dilute sulphuric acid, and as hot as can be borne. These draughts are to be given *nolens volens*, as often as every five or ten minutes if rejected, but less frequently if retained: At the first appearance of coldness of the hands and feet, if the vomiting and purging continue, in conjunction with the hot drinks injections must begin, while yet the circulation is little impaired and the absorbents are active. Large volumes of saline water of the temperature of 100° F. are to be thrown slowly into the loose areolar tissues at all available points of the *trunk* from a syringe of large size. The needle should be inserted at many points on each occasion, if the quantity of fluid needed be considerable; a matter to be determined in each case by the condition of the subject and the amount of serum being lost. If done early, from one to four quarts of fluid I am sure may thus be thrown into the blood channels, if needed, within the space of an hour, and must be repeated again and again as occasion may demand. Dr. T. Weatherill (*Lancet*, 1832, ii, pp. 688–689) related a case in which 480 ozs.—3$\frac{3}{4}$ gallons—were injected into the *veins* with success. To this artificial serum may be added alcohol, carbonate of ammonia or other adjuvant.

When my first paper appeared it called forth some comment from the medical press, and some objections were raised. No one thought the practice would prove hazardous, but some objected under the belief that a quantity of fluid sufficient to serve any valuable purpose would not be absorbed—an objection without validity except when the measure is resorted to in unfavorable conditions, as in complete collapse, when absorption would be slow indeed, and perhaps wholly suspended. A more weighty objection is found in the possibility that no artificial serum can supply the physiological place of the lost serum of the blood. Even this objection, however, loses much of its force when we remember the readiness with which the organism conforms to new conditions, as seen in the transfusion of blood, but in a more marked manner in the successful transfusion of so incongruous a fluid as milk.

After a somewhat critical examination of the subject I am prepared to suggest the following as a good, if not the best, formula for the injection fluid: ℞. Sodii chlor., ʒjss; sodii sulph., ʒjss; potass. chlor., grs. viii; sodii phosp., grs. v; sodii carb., grs. xxxij; alcoholis, fʒiij; aq. dest. q. s. ad., f℥xxxij. This is a modification of the fluid used in intravenous medication and known as Little's solution, of which, however, the sodium sulphate is not a constituent. A convenient form for ready use would be a strong, filtered solution, preserved in well-stoppered two-oz. bottles, each containing enough to make one quart of the injection fluid when added to a sufficiency of recently distilled water. A very neat, nicely adjusted and close-fitting four-oz. syringe, with three needles, has been made for me, according to instruction and design, by George Tiemann & Co., 107 Park Row, New York, of whom it may be had. The instrument should be thoroughly rinsed in a 5 per cent. solution of carbolic acid before and after using.

Now this paper, since it is to be published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, will have wide circulation, and in order that it may fulfil its mission, and the method of treatment suggested on trial be rated fully at its merits, a word more must be said respecting the manner of its execution. A disease that carries off its victims in twenty-four hours, and sometimes in four or five, cannot wait for the slow-coming feet of the slothful, nor the hesitating hand of the unready. Its management requires generalship. The physician must have power to command himself, and command unquestioning obedience on the part of others. Milder measures having failed, the treatment here enjoined must be followed with unflinching purpose and be rigidly enforced on all who are about the patient. Do not despair of saving your patient, but press your efforts even to the jaws of death. If in deep collapse from lack of early treatment, and the fluid be not absorbed from the cellular spaces, thrust the needle into the median basilic or median cephalic, or other accessible vein in the arm or leg, and practice intravenous injection. The operation will probably be quite as free from danger with my syringe made for intra-areolar injection as if done with a more elaborate appliance. It can be done in a few moments by a dexterous hand, and only requires that all air be expelled from the needle before inserting it, that the injection be made slowly, and that the syringe be not completely emptied. About one in every six of the cases tried have recovered from deep collapse under intravenous injection, if the reports are to be relied on.

Now it may be asked just here, what advantage the proposed plan of intra-areolar injection has over intravenous injection of saline solutions; and the answer is, that by the intra-areolar method the fluid is introduced at many points, distant from each other, and slowly and by a sort of filtration through many small and diverse channels, enters at last the ascending and descending venæ cavæ and reaches the heart in a gradual way. Owing to the means, too, by which the fluid reaches the large venous trunks, there is no danger of the entrance of air. The same things cannot be said of intravenous injection, for the fluid is thrown into a vessel of considerable size, and unless done with great caution, may endanger fatal engorgement of the heart if that organ happen to be nicely balancing between action and rest. It also endangers entrance of air and, what is by no means impossible, embolism, from the wounded vein. These considerations point out one other great advantage of the intra-areolar over the intravenous method. The first can be used with safety, even by the unskilful, who are many, but the other must be relegated to the skilful, who are few.

That the plan of treatment I advocate will greatly lessen the fatality of the disease I believe—that it may fall short of my expectations is possible. The most that can be said against it, perhaps, is that it is untried, and the same has been true of every successful remedy in medicine and every valuable appliance in surgery till their merit had been proved by trial.

It will be seen that I have omitted discussion of the cause, the mode of propagation, the symptoms and pathology, the prevention, and all details as to treatment, except so far only as has been necessary to illustrate the innovating methods herein set forth. It may not be amiss, however, if I give here a simple and palatable formula for the use of the well-known remedy, sulphuric acid, as a personal prophylactic for those who are being actually exposed to the danger of infection: ℞. Acid. sulph. dil., fʒij; spts. vin. gal., f℥ij; syr. aurant. f℥viij. M. Sig. A tablespoonful half an hour before, and two hours after each meal, in a half tumbler of water.

The supreme value of such prophylactic measures for those who are exposed, and the priceless advantage gained by interception of the virus on its way to the intestinal canal, and while yet in the stomach, must be borne in mind if we would discharge the duty our profession imposes. It may not be out of place if I say, in conclusion, that much of the contents of this paper is based on observations made during the prevalence of the epidemic of 1848–1849, and of 1866, in both of which the writer bore an active part.

PURULENT BRAIN DEPOSITS, AND PHLEBITIS AND THROMBOSIS OF THE CEREBRAL VEINS AND SINUSES FOLLOWING EAR DISEASE.

BY FRANK ALLPORT, M.D.,
OF MINNEAPOLIS, MINN.,
PROFESSOR OF CLINICAL OPHTHALMOLOGY AND OTOLOGY IN THE UNIVERSITY OF MINNESOTA, ETC.

(*Continued from page 502.*)

Case 27.—Archives of Otology, September, 1880.—Treated by J. Michael, of Hamburg. Left ear. Chronic otorrhœa. Years ago received a blow on left side of head; insensibility for a few hours followed; in a few days recovery occurred, with an occasional pain on the left side of the head. He has had a discharge from both ears, and been rather deaf for the last two years.

Nov. 10, 1877. Violent headaches, starting on left side. He has a feeling of pressure, feels stupid and has slight aphasia. He lies in bed with his head drawn somewhat downward into his neck; his face is red; pupils sluggish; constipation; no fever; aural polypi in both ears; removed; syringe; calomel and ice bags; no improvement.

Nov. 16. Spasms and unconsciousness. Stiff flexion of all four extremities. Then followed delirium, stupor, sensitive skin; pain upon moving back. Death.

Autopsy.—A yellowish projecting spot existed somewhat above the surface of the dura-mater, over the crista superior of the petrous bone. This corresponded to the site of the injury. The pia-mater at the convexity covered with pus. Abscess in left temperosphenoidal lobe. The ventricle was filled with pus. An opening existed outward from the corpus striatum, communicating with the abscess. Temporal lobe largely broken down with purulent degeneration. The frontal lobe œdematous and softened. The right lateral ventricle, as well as the third and fourth, was filled with a purulent fluid. The pia-mater at the base charged with pus. This extended down the vertebral canal. Both mastoid cavities were filled with pus.

Case 28.—Lancet, May 28, 1880. Treated by Henry Morris. Male, age 31. Left ear. Chronic otorrhœa, deafness, pain, red mastoid, chills, unconsciousness. Mastoid opened, temporary improvement, then pyæmia, herpes on face. Death.

Autopsy.—Thrombi in left lateral sinus and jugular vein.

Case 29.—Archives of Otology, September, 1880. Treated by Eugene Frankel. Female, age 23. Left ear. Chronic otorrhœa, acute exacerbation, meningitis. Death.

Autopsy.—Pus in tympanum; opening through drum-head; thrombo-phlebitis of transverse sinus; abscess in sub-dural space and in left temporal lobe; purulent lepto-meningitis of the base and the convexity.

Case 30.—Archives of Otology, September, 1880. Treated by Eugene Frankel. Male, age 22. Right ear. Chronic otorrhœa, appearance of cerebral symptoms after a knock on the head. Death.

Autopsy.—Pus in tympanum, no perforation of drum-head, incus gone. Caries of petrous bone, through roof of tympanum. Abscss in right temporal lobe, encapsulated. Thrombo-phlebitis of right transverse sinus.

Case 31.—Archives of Otology, September, 1880. Treated by Eugene Frankel. Female, age 28. Chronic otorrhœa. Right facial paralysis, vomiting, retained urine, dilated pupils, mastoid not opened; coma. Death.

Autopsy.—Pus in tympanum, perforation of drumhead. Caries of roof of tympanum and of ex. aud. meatus. An inspissated exudation compressed the facial nerve in the Fallopian canal. Purulent basilar meningitis; abscess in right temporal lobe, encapsulated. Mastoid sclerosed.

Case 32—Archives of Otology, September, 1880. Treated by Eugene Frankel. Male, age 53. Left ear. Chronic otorrhœa, polypus, removed, headaches, mastoid opened, meningitis. Death.

Autopsy.—Epithelioma of left ear, with destruction of most of the temporal bone. Purulent basilar meningitis.

Case 33.—Archives of Otology, September, 1880. Treated by Eugene Frankel. Female, age 3. Left ear. Pebble in left ex. meatus, attempt at removal, meningitis. Death.

Autopsy.—Drum-head gone. Pebble in middle ear, pus in middle ear. Purulent meningitis of the convexity.

Case 34.—American Journal of Otology, No. 3, 1879. Treated by J. Orne Greene. Otitis media, polypus, vomiting, pain, convulsions. Death.

Autopsy.—Carious destruction of vault of tympanum. Perforation of dura-mater near transverse sinus. Abscess of temporal lobe.

Case 35.—Lancet, 1878, vol. I, No. 20. Treated by G. C. Gribbon. Male, age 22. Right ear. Chronic otorrhœa, drum-head destroyed, violent headache, nausea, paresis of lower extremities. Death.

Autopsy—Abscess in right lobe of cerebellum. Caries of petrous bone at the internal auditory meatus. Pus in mastoid cells.

Case 36.—Archives fur Ohrenheilk., vol. xix, No. 4, page 245. Treated by K. Burkner. Male, age 36. Right ear. Chronic otorrhœa, pain in ear and head, deafness, diminution of discharge, convulsions, delirium, coma, œdematous swelling over superior boundary of mastoid muscle, a probe passes through posterior superior wall of external meatus, reaches carious cavity. Death.

Autopsy.—Necrosis in tympanum and external meatus. Dura-mater in region of temporal bone is injected, thickened and covered with pus.

Case 37.—Archives fur Ohrenheilk., vol. xix, No. 4. Treated by K. Burkner. Male, age 20. Left ear. Chronic otorrhœa (bilateral), sudden pain in left ear, cessation of discharge, chills, vomiting, vertigo, high fever, a thrombus felt in the left jugular, pain in neck, apathetic condition, left mastoid red and swollen, facial veins enlarged. Death.

Autopsy.—Thrombi in transverse sinus and in bulbous venæ jugularis. Red points and minute holes in the thin jugular fossa.

Case 38.—Archives fur Ohrenheilk., vol. xix, No 4. Treated by K. Burkner. Male, age 17. Left ear. Acute purulent otitis, left facial paralysis, granulations in middle ear, removed, improvement; some weeks later had sudden pain in ear. Discharge stopped, return of bad symptoms, contraction of left pupil, nystagmus of both eyes, somnolence, total deafness of left ear, paresis of left leg, paralysis of left abducens, pain in all branches of the trigeminus, vomiting. Death.

Autopsy.—Pus around chiasm. Anterior extremity of left lobe of cerebellum is adherent to the posterior margin of the temporal bone. Abscess in left pons. At the superior border of the temporal bone, are three small carious openings, communicating with an irregular cavity, involving the entire posterior portion of the temporal bone. This cavity is filled with a greasy, shining, yellowish-white mass, which infiltrates the posterior wall of the temporal bone, just above the sigmoid sulcus, and is also connected with the vestibule. The ossicles are gone. Internal ear destroyed by gelatinous mass.

Case 39.—American Journal of Otology, April, 1881. Treated by E. G. Loring, of New York City. Male. Middle age. Right ear. In April, 1878, he consulted Loring with influenza, poor hearing, closure of Eustachian tubes. Recovered. December, 1878, had a similar attack. Recovered. December, 1879, had frequent similar occurrences. April, 1880, pain in ear and side of head, acute catarrhal otitis. Improvement. A few days later had severe pain again. Delirium, drum-head punctured, no pus. Death.

Autopsy.—Dura-mater intensely congested at the roof of the tympanum. Sero-purulent exudation in sub-arachnoid space. This exudation extends from the longitudinal fissure down upon the side of the brain. Pus in upper surface of right lobe of cerebellum. Pseudo-membrane in tympanum.

Case 40.—Archives der Heilkunde, vol. ii, page 295. Treated by H. Wendt. Male, age 49. Right ear. March 13, 1869, consulted Wendt. Tinnitus aurium, pain, deaf. March 30. unconsciousness, convulsions. Death.

Autopsy.—Basilar meningitis.

Case 41.—Archives der Heilkunde, vol, ii, page 295. Treated by H. Wendt. Male, age 52. Right ear. Caught cold, acute catarrhal otitis, perforation of drum-head, pain and tinnitus aurium. Found dead in bed.

Autopsy.—Diffuse meningitis.

Case 42.—Archives der Heilkunde, Vol. ii, p. 295. Treated by H. Wendt. Traumatic inflammation of middle ear; death.

Autopsy.—Basilar meningitis.

Case 43.—Service of E. de Rossi, of Rome. Female, age 57. Left ear. September, 1880, had malaria, went to the hospital. Three weeks afterwards had tinnitus aurium in the left ear, no pain. Acute otorrhœa. February 1881. Left side of neck swelled. March 2. Swelling incised and pus evacuated. March 3. Swelling increasing, painful to pressure, pus comes from meatus on pressure of swelling. Polypus in middle ear; middle ear is also connected by a sinus with the swelling. An attempt to open mastoid was made, but extreme sclerosis prevented. Chills; death.

Autopsy—Coagulated blood in left sinuses, localized meningitis, clot in jugular vein, caries of atlas and second vertebra, pus in cavum tympanum, occipital condyles carious, pus in mastoid cells. Carious opening in posterior walls of mastoid antrum, communicating freely with sigmoid sinus. Transverse sinus surrounded by pus.

Case 44.—Service of E. de Rossi, of Rome. Female, age 18. Right ear. Chronic otorrhœa. January 6. Pain in ear and side of head; fever. January 9. Came to the hospital. Deafness; tympanic granulations removed. Improvement. Headache, fever, exophthalmia, ptosis. Violent pain in head, painful swelling over mastoid muscles. Coma, death.

Autopsy—Dura mater adherent to the bone. Pus in subdural space, corresponding with the inferior side of the frontal and sphenoidal lobe and the anterior margin of the right hemisphere of the cerebellum. Pus covered the trigeminus and acoustic nerves. Dura mater at base of skull covered with pus; superior petrosal sinus, inferior cavernous sinus and transverse sinus filled with pus.

Caries was found in that part of the base of the skull which corresponded with the tegmen-tympani. Pus in tympanic cavity. The pus had burrowed laterally in the subdural space to the entire extent of the right lobes of the cerebrum and cerebellum. Several of the large veins which opened into the longitudinal sinus showed thrombi; thrombus in longitudinal sinus; abscess in the inferior posterior side of the frontal lobe.

Case 45.—King's College Hospital Reports. Treated by Urban Pritchard, of London. Male, age 23. Left ear. Chronic otorrhœa. Frontal headache, pain in left ear. April 1889. Caught cold; increased discharge and pain; several attacks of unconsciousness, with loss of speech. June 17. Convulsions; twitching of left side of face; semiconsciousness; fits. June 23, 1889. Came to hospital. Drowsy, incoherent. Tenderness on pressure, most marked about two inches above meatus. Slight facial paralysis. Operation June 23, 1889. Skull trephined at a spot about 2 inches above, and ½ inch in front of the meatus; no pus. Trephined again 1 inch behind the original opening. Pus found outside of dura mater. Trephined again over occipito-parietal region; no pus. The dura mater was at all times left intact. The whole wound was thoroughly irrigated and dressed antiseptically. Recovery. Occasionally has short attacks of aphasia.

Case 46.—King's College Hospital Reports. Treated by Urban Pritchard, of London. Male, age 26. Left ear. Chronic otorrhœa. Pain in the ear, and swelling of left side of neck. September 7, 1889. Intense pain in ear and side of head; chills; vomiting. September 11. Came to hospital. Intense pain in head, focussing in left temporal fossa; dizzy; polypus in middle ear. September 14. Temperature 101°. Delirium, vomiting, twitching of left eyebrow and angle of mouth. September 16. Retention of urine; semi-conscious. Operation. Trephined 1½ inch behind the meatus, and the same distance above the cerebral base line; pus evacuated, brain débris removed. Wound irrigated, drainage tube, antiseptic dressings. Improvement, delirium, chills. September 24. Wound re-explored, no pus; mastoid opened, no pus. September 26. Paralysis of right arm and leg. September 30. Optic neuritis, left eye. October 2, the track of the drainage tube was freely dilated; pus escaped. Slow recovery; still has chronic otorrhœa; has had two attacks of unconsciousness since discharge, and once some aphasia.

(*To be continued.*)

DR. J. COLLINS WARREN, of the Harvard Medical School, has accepted the executive presidency of the Section on Medical Pedagogies of the Pan American Medical Congress.

LUMBRICOIDAL OBSTRUCTION.—The *Doctors' Weekly* states that Dr. John Wyeth, of the Mount Sinai Hospital, New York, had a case of intestinal obstruction upon which he operated and removed a mass or entanglement of lumbricoids, eighteen in number; some of the worms were seven inches long. The patient did well after the operation and recovery is seemingly assured.

THE
Journal of the American Medical Association
PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE:
PER ANNUM, IN ADVANCE $5.00
SINGLE COPIES. . . . . 10 CENTS.

Subscriptions may begin at any time and be sent to
THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,
NO. 68 WABASH AVE., CHICAGO, ILLINOIS.
All members of the Association should send their Annual Dues to the Treasurer, RICHARD J. DUNGLISON, M.D., Lock Box 1271, Philadelphia, Pa.

MEMBERSHIP IN THE AMERICAN MEDICAL ASSOCIATION.

This is obtainable, at any time, by a member of any State or local Medical Society which is entitled to send delegates to the Association. All that is necessary is for the applicant to write to the Treasurer of the Association, Dr. Richard J. Dunglison, Lock Box 1271, Philadelphia, Pa., sending him a certificate or statement that he is in good standing in his own Society, signed by the President and Secretary of said Society, with five dollars for annual dues and subscription for THE JOURNAL. Attendance as a delegate at an annual meeting of the Association is not necessary to obtain membership. On receipt of the above amount the weekly JOURNAL of the Association will be forwarded regularly.

SATURDAY, OCTOBER 29, 1892.

PROTECTIVE VACCINATION AGAINST CHOLERA.

It is generally admitted that the discovery of the cholera bacillus has given the profession a certainty in the diagnosis of sporadic cases of cholera, which we could not possess without it. Indeed, the importance of the search for the cholera bacillus is emphasized by the latest report by GUTTMANN from the Berlin cholera hospital, who proved by the detection of the specific germ, that apparently inoffensive cases of diarrhœa may really be mild attacks of genuine cholera. While it is evident that bacteriological advance has thus increased materially the efficacy of prophylactic measures, it cannot be claimed that it has as yet aided the therapeutics of cholera. Reports from various sources, however, indicate that the problem of protective vaccination against cholera is nearly solved.

The first efforts to immunize animals against infection with cholera bacilli, or against poisoning by their products, were reported by BRIEGER, KITASATO and WASSERMANN. Theoretical reasoning led these investigators to the experiment of growing various pathogenic bacteria in infusions of the thymus gland, or at least mixing pure cultures with this infusion, in the hope of reducing the bacterial toxicity. This expectation was realized, and such cultures, rendered less poisonous by the influence of the thymus extract, proved efficient protective vaccines against inoculation with the more virulent bacteria in tetanus, diphtheria, typhoid fever, erysipelas and cholera.

If a culture of cholera germs grown in thymus broth is heated to 65° C. for fifteen minutes, it becomes harmless to guinea pigs, but after twenty-four hours protects the animals against inoculation with twice the fatal amount of virulent bacilli.

Meanwhile researches with a similar object in view had been carried on by HAFFKINE in PASTEUR'S laboratory. This author found that he could modify the virulence of the cholera germs by special modes of culture. By growing them in broth at a temperature of 39° C. with steady aeration, he could diminish their toxicity to animals. On the other hand, by passing the virus through a series of guinea pigs by intra-peritoneal injection, the virulence was intensified. The former variety, introduced under the skin of animals or man, gave rise to localized swelling and œdema, and some febrile reaction. The intensified virus produced a more serious local reaction and even necrosis of the tissues, but *not if preceded by inoculation with the weaker virus six to eight days previously*. An animal that has passed through these two vaccinations is now proof against the ordinarily fatal injection into the peritoneal cavity. HANKIN describes in a recent number of the *British Medical Journal* the effects of such a vaccination on himself and others under the direction of HAFFKINE. There is, however, no direct proof as yet that these procedures protect man against the natural mode of cholera infection, although the analogy with observations on animals, as well as the tolerance to subsequent subcutaneous introduction of cholera virus, render this a probable presumption.

HAFFKINE'S method has been tested by the now famous journalist STANHOPE, who then exposed himself as cholera nurse without precautions in the Hamburg hospital, and even drank the suspected Elbe water. Yet such a sensational experiment cannot be of much scientific value. Since cholera does not attack every person exposed to it, his escape is not a decisive proof of the efficacy of the vaccination, while if the man had succumbed it would only have shown that the method is as yet not infallible.

A more definite proof that it is possible to render man refractory against cholera infection has been furnished by G. KLEMPERER, of Berlin. Two years ago BEHRING discovered that the serum of an animal artificially immunized against diphtheria could neutralize the toxic products of the diphtheria bacilli; virulent diphtheria cultures can thus be rendered harmless by mixture with a sufficient quantity of serum from an immunized animal. On the other hand the injection of such serum under the skin of a fresh animal protects the latter temporarily against a subsequent inoculation with diphtheria cultures. The anti-toxic effect of the serum depends on its quantity and upon the degree of immunity conferred upon the first animal. This discovery of BEHRING'S of the specific anti-toxic properties of the serum of immunized animals has since been found to apply also in many other bacterial diseases against which immunity can be obtained—as tetanus, pneumococcus poisoning, typhoid fever, erysipelas and some others KLEMPERER has ascertained that this is also the case in cholera.

He reasoned therefore that if a vaccination is to protect against cholera it must give the serum of that individual the property of neutralizing the poisons produced by cholera germs. For this had been positively shown by his experiments on animals.

Since epidemiological experience has shown not all persons are apt to contract cholera he tested in the first place whether the blood of non-vaccinated persons ever possesses anti-toxic properties. In two instances out of five venesections he found that one to two centimetres of serum *were sufficient to protect* guinea pigs against cholera inoculation. His most important object viz.: to compare with this normal state of affairs the anti-toxic power of the blood of cholera-convalescents, he had not had opportunity to attain at the time of writing.

By inoculating a human being with cholera cultures heated to 70° C. for two hours by means of subcutaneous injections given eight successive times during 12 days, he obtained a high degree of immunity as manifested by the anti-toxic properties of the blood. A quarter of a cc. of this serum was a sufficient protection to guinea pigs. But the time and number of the injections required would deprive the method of its practical value.

By varying the method in very cautious trials on many students and colleagues, KLEMPERER finally learned that the living cholera bacilli so terrific in their power when introduced into the bowels, are relatively harmless when put under the skin of man. A severe but not dangerous local reaction and some fever follow the injection, but the bacilli are evidently killed by the organism. Within three days after the infection of .35 cc. of a liquid culture of cholera bacilli of full virulence a high degree of immunity was found established.

It is but justice to add that these results obtained by competent observers and by means of precise methods confirm on the whole the claims of FERRAN who alleges to have protected numerous persons by cholera vaccinations eight years ago. FERRAN'S methods were not *sufficiently precise*, *nor were they* revealed to a sufficient extent to convince the profession of the reliability of his claims.

INEBRIETY AMONG WOMEN IN THIS COUNTRY.

The *British Medical Journal* gives a startling picture of the increase of inebriety among women in England, and also in other parts of the world. The number of women convicted of drunkenness in England and Wales, rose from 5,673 in 1878, to 9,451 in 1884. Last year 33,000 females were convicted of drunkenness in the United Kingdom. In London in one year the increase of convicted women was 500. In Glasgow 10,500 women were sent to prison. Of this number 450 were sent to jail from six to thirty-four times during the year. In Ireland the champion female inebriate record-breaker has been arrested over 700 times, and is yet less than 40 years old. One woman was sent to prison fifty-two times during twelve months. The proportion of women arrested was formerly seven men to one woman; now it is three men to one woman. The ages of these offenders range from 12 to 60.

These figures are so appalling as to be called a "*National shame*" by the daily press. Such persons do not come from the lower circles alone, but represent all classes and conditions of society. Twenty years ago women were not seen in the bar-rooms; now they are very common. The editor thinks that this increase of inebriety extends to all civilized countries in proportion. Unfortunately, we have no statistical studies of the number of women who come under police notice for inebriety. The partial records of a few large cities show a decline of inebriates among women, and these are among the lowest class of foreigners. Some authorities are confident that opium and other drug inebriates are increasing among women. There are probably many good reasons for this belief, especially among the middle and better classes of society. Such reasons are based on the individual observations of family physicians, and not on any statistics that can be gathered. Persons who have had large experience in institutions for inebriates, where they would naturally hear or be advised of such cases, are agreed that the number of alcoholic women among inebriates is very small comparatively; also that such cases merge more quickly into acute forms of delirium and melancholia, and disappear from the homes and the street. It may be safely asserted that the American woman cannot constitutionally use any form of alcohol as her foreign sisters use it. She has a more acute nervous organization, and the brain centers are more unstable; the surroundings are full of psychological factors that keep up a certain nerve tension, which antagonizes the sudden increased heart's action from alcohol. The brain suffers from the strain of alcohol, which gives no pleasure. The American women of all classes want rest, not increased excitement, hence they seek this more naturally in narcotics. There are other physiological reasons why alcohol is not used by women in America. From heredity and many other conditions, with surroundings and predisposing causes, inebriety will be found among women, but it will be of shorter duration in this country. It will be a symptom more than a disease; a symptom of brain and nerve failure, of rapid degeneration, that quickly takes on other forms. The American woman will never be a record-breaker for arrests for inebriety.

As a drug taker or an opium inebriate the same rapid fatality follows. As a periodical drinker, profound neuroses come on and the drink craze changes. The *British Medical Journal* urges very wisely, that this "National folly" of arresting and sending to jail these poor victims, should cease. A new departure is demanded, and they should be recognized as diseased and sent to hospitals, under the care of physicians. A long residence in such a hospital would be an experiment that would be infinitely more humane, hygienic and economical, and fraught with the most important results to both the race and civilization. The practical point for our American physicians is to take up the subject of inebriety and study it as a purely medical topic, and not leave it to police courts and moralists to point out the evil and its remedies. The British public are alarmed at the extent of the evil, and cast about wildly for help. If the medical public had made this a scientific study, they would long ago have pointed out the means of prevention and cure.

The same thing is repeated here. The drink problem including both men and women, and the use of all narcotic drugs, are studied by moralists and non-experts. and the medical profession, to whom it rightly belongs, "pass it by on the other side." Both alcoholic and opium inebriety have already invaded our cities, neighborhoods, and even our homes, and the pledge, the prayer, the police court and punishment are the only remedies we can offer. Moral, religious and knavish quacks offer all sorts of specifics, but the evil goes on unchecked. The time is coming when the medical profession will teach the world the causes and remedies for this great and widespread evil of the century.

FIXATION OF THE SHOULDER IN THE TREATMENT OF DISLOCATION.

SURGEON-MAJOR HAMILTON, of the British Army, has made use of inelastic webbing to obtain fixity of the arm and shoulder. His method has been found effective in the dressing of a dislocation upward of the outer end of clavicle. According to the *American Practitioner and News*, July 30, the steps of the process of MR. HAMILTON are: first, the surgeon places a very large pad in the axilla of the affected side, and then passes around the arm of that side and so on around the body a piece of soft inelastic webbing about 1½ inch wide; this band is made to overlap 3 inches. The ends are held by stitching. Another piece of the same webbing is stitched at the back to the body-belt; brought firmly over the point of luxation, over which is placed a pad secured in place by stitching to the underside of the second strip; then made fast by sewing to the body-belt in front. In order to maintain downward traction, a perineal band is made to pass from the body-belt behind to a buckle attached to the same in front. The hand and forearm must be carried in a short sling. It is only necessary to unbuckle the perineal band when the patient goes to stool. MR. HAMILTON finds that this apparatus furnishes an absolute fixity of arm and shoulder.

NAVAL SURGEONS VOLUNTEERING FOR MILITARY HOSPITAL DUTY.

In the recent civil warfare in Venezuela some of our naval surgeons have done honorable and humane emergency service. After the skirmishes that took place near La Guayra a considerable number of revolutionists, though badly wounded, were without any surgical aid. Some of them lay for hours without even a primary dressing for their wounds. This state of affairs having come to the knowledge of the American (United States) naval officers, Medical Inspector TYRON, of the Chicago, went to the front and organized a hospital service at Macuto. He was assisted by two junior surgeons of the Chicago, and by the surgeons of Spanish, English and German ships in port. The men whom they went to serve had neither surgeons nor supplies.

DR. TYRON and his staff were obliged to find their own instruments, bandages, appliances and medicines. One of the surgical staff of the Chicago, remained at the hospital every night. Some of the operations, such as resections at the hip and shoulder, required constant supervision; gangrene was not wanting in two or three cases to complicate the surgeon's duties. All honor to the Chicago's staff, and to their humane colleagues!

EDITORIAL NOTES.

KING'S COLLEGE, LONDON.—This institution, best known in this country by reason of being the field of Sir Joseph Lister's later labors, is also one of the centers of post-graduate instruction. It is there that the lectures and laboratory tuition of Professor Cruikshank are given in bacteriology. It was there that Sir Thomas Watson and Budd, Ferrier, George Johnson and Playfair have wrought and pursued their respective investigations beneficial to progressive medicine. A singular feature is noted in the London *Echo*, that while the institution is called a "college," it is worthy to be ranked as a University, and that although it bears the name of the King, it is the most democratic movement in London's educational enterprises. "The practical character of this democratic institution is its great glory." Nearly 600 students are now connected with this "Poor Man's University"—the evening classes at King's. That this has been a boon to the poorer part of London's great life is a fact impossible to exaggerate.

IN Dr. Billings' National Medical Dictionary, one-third of the terms defined are Latin, being only 1,500 less than the English. We must also not fail to take into account the words derived from the Latin but incorporated into English and not credited to their Latin origin. "The practice of adding to the English vocabulary words adopted from the Latin and Greek is still carried on with activity, and there is little prospect of its ceasing. It is almost necessary as a means of denoting those new objects, ideas and relations, which are continually appearing and demanding expression. The resources of the English for the formation of new words from elements already existing in it are so limited that aid from other languages is indispensable. The new terms which are required by the progress of science are almost wholly derived from these sources." ["Brief History of the English Language" prefixed to Noah Webster's Unabridged Dictionary, Ed. of 1884.] A few minutes devoted to Latin daily will lead to wonderful results if persevered in for a sufficient time.

Twenty-five Cases of Extirpation of the Uterus from Cancer. A Consideration of Ultimate Results.—Dr. Charles A. L. Reed, of Cincinnati, presented to the recent meeting of the American Association of Obstetricians and Gynecologists, a report of twenty-five cases of complete vaginal extirpation of the womb for cancer with only two primary deaths—one from shock and one from iodoform poisoning. Of the twenty-five operated upon, but fourteen were of more than two years' standing, and hence were all that could be discussed with reference to their ultimate results. These fourteen were divisible into two classes of seven each, viz.: those in which the disease had existed for more than six months before the operation, and those in which it had existed for less than six months before the operation. Of the first class, *i. e.*, those of more than six months' (an average of 10 months) previous duration, all were dead; of the second class, *i. e.*, those of less than six months' (an average of 4 months) previous duration only one has since died. One of the recoveries is of more than five years' duration. The conclusion from these figures is that cases of cancer of the uterus ought to be remanded for operation as soon as diagnosed. Dr. Reed looks upon total extirpation as the only operation to be advised or practiced in these cases, the primary mortality from which, in experienced hands, varies from five to eight per cent.

Trans-Atlantic Fraudulent Preparations.—The American drug-consumer appears not to have a monopoly of fraudulent pharmacals. Dr. Alfred Hill, the public chemist for the city of Birmingham, England, reports that six specimens of Seidlitz powders, sent to him for analysis, were found to be impure, and out of fifteen specimens of sal volatile six were below the standard.

A pharmacist of Londonderry was recently tried and fined for selling the tincture of iodine and compound benzoin tincture made with methylated spirit. The only defense that was attempted was that this kind of tincture was never dispensed except upon a prescription marked "for external use."

The *Pharmacie Centrale*, of Paris, has given warning that attempts have been made to market an adulterated iodoform gauze that contains not more than eight per cent. of iodoform, whereas it is represented to contain 30 per cent., the difference in color being made up by the addition of a certain amount of phenol.

The True Physician.—Dr. T. Frazer Thomas, of Gainesville, Florida, is the author of the following sentiment touching the relations of the medical man to the lowlier members of his constituency: "The true physician will respect the feelings of the poor, both by the language and tone of voice in which he addresses them. He will remember that disease is his only passport to any house. He will act as a gentlemen to all, to the low, to the vile even, as well as the gentle and the rich. His duty is to heal, not to punish." Boerhaave said that "the poor were the best patients, for God is their paymaster." Because the physician receives no tangible recompense he must not forget his obligation to his patient nor his own self-respect.

In his intercourse with the world he must not be swayed by prejudice nor nationality. Friendship and good-will for all his patients are his polar stars, ever keeping in remembrance the priceless precept, "There is but one country—the earth; but one nation—the human race."

DOMESTIC CORRESPONDENCE.

PHILADELPHIA LETTER.

All danger of our having an epidemic of cholera being over for this year, quarantine vigilance has now relaxed, so as to detain only those vessels which have actually sickness on board or the cargoes of which consist of rags or other probably infected material. It is only justice to state that the escape of the community from the scourge is unquestionably due to the timely activity and unceasing exertions of our city and State health authorities. One of the measures calling for special mention is the employment of microscopical experts by the city authorities, so that in all cases in which bowel disorder aroused suspicion of cholera infection, bacteriological examinations and cultures were systematically made. The result was that in no instance was Koch's comma bacillus detected. Notwithstanding the proximity of vessels from infected ports which were lying in the river, it can be said that not a single case of cholera occurred in Philadelphia. This city is peculiarly fortunate in the fact that it is doubly protected by having the national quarantine at the Delaware Breakwater at the head of the bay, and by the State and City Lazaretto on Tinicum Island in the Delaware river near Chester. The situation for a time was grave enough however, and the air was filled with complaints of the interruption of commerce and detention of passengers, owing to a little clashing of authority between the city and State officials, just as occurred in New York between the local and National representatives. As a result an unexpected element of humor was introduced, for which we are indebted to the iconoclastic spirit of the Lazaretto physician, whose daily official communications to the city authorities were frequently couched in language more forcible than polite. He objected in vigorous terms to the "red tape and monkey business" of formal quarantine, and denounced "wind-mill legislation of health boards," which detained persons, "who had not cholera and had not been exposed to it," under conditions of great personal discomfort and in a place where they were certainly in danger of malarial poisoning. Finally the patience of the city board being exhausted, it resolved to return the last two communications of Dr. Herbst, and not to receive any more of his letters unless restricted to strictly official matters and language.

The indications are now pointing strongly in the way of a formal request being made to Governor Pattison to remove the Lazaretto physician, who, whatever may be his shortcomings in the way of respect for Health Boards, is not deficient in performance of duty, as a *persona non grata* and to replace him with one more in harmony with the city authorities. Among the vagaries of the late campaign might be mentioned the startling proposition of the City Health Officers, to quarantine this city against New York and to shut off all intercourse during an indefinite period during which cholera might be present to a greater or less extent in the latter city. The State Board of Health made an appeal for an appropriation to maintain some thirty-nine quarantine stations along the border of the State so as to prevent the importation of cholera. In order to make this in any way effective a standing army or cordon of sanitary police would be required to guard the border line, but even shot guns would not be successful in keeping out the infection unless all the water courses were also protected to their very sources. Moreover, land quarantine on any extended scale is a poor reliance at best because necessarily imperfect. The City Board of Health went to work with a will to avert the possibility of the epidemic gaining a foothold here. They paid especial attention to the sanitary condition of the city and extra inspectors were appointed and sent out to make house-to-house examination for nuisances, which were promptly abated. City pumps were condemned and ordered closed. Printed leaflets was distributed by the police force to house holders, giving directions for removing garbage, using disinfectants and white-washing cellars and out-houses. City Councils appropriated $50,000 for the special work of preventing the epidemic, etc., etc. As before stated, the several health authorities may be complimented upon the fact that not a single case has yet appeared and that the city is at present in a superior sanitary condition. It is true that within the past two or three weeks there has been something of an outbreak of diphtheria, and the Health Board successfully petitioned Councils to have $10,000 of the special cholera fund, devoted to stamping out this disease which has been prevailing to a moderate degree, from seven to ten or more cases being reported daily. About 72 deaths have occurred from diphtheria during the last two weeks, but the Board of Health denies that it has assumed the proportions of an epidemic and by promptly quarantining infected houses, isolation of cases, and thorough disinfection, it is believed that the disease is now kept fully under control.

Among the special benefits conferred by the cholera scare may possibly be additional facilities for the quarantine station at the Lazaretto, at Big Tinicum Island in the Delaware river, by establishing upon a neighboring island (Little Tinicum) suitable barracks, administration and hospital buildings, wharf, disinfecting plant, etc., covering an area of some twenty acres. This would make a commodious and complete quarantine station fully abreast of modern requirements. These plans it is said have been approved by the Commission appointed at the meeting of the International Conference of State Boards of Health held recently at Indianapolis, the said Commission having been directed to visit and inspect all the quarantine stations of North America. The Mayor has made this the subject of a communication to Councils urging the adoption of the plan and also the immediate construction of the buildings, so as to be prepared for a possible invasion of cholera next year. Unless, after conference with the National quarantine authorities, it is decided to combine the two stations in some other location, it is likely that this suggestion will be followed, and that Councils will make the necessary appropriation. Another incidental advantage which might be named was the appointment by Governor Pattison of Dr. E. S. Shakespeare as Port Physician, who has officially made a special study of cholera, having been commissioned by President Cleveland to visit Europe and report upon cholera to the Government, which report has recently been issued.

"The Pennsylvania Society for the Prevention of Tuberculosis" has been formed and has commenced its crusade against this great modern scourge by educating the public by the publication of tracts for gratuitous distribution. The first one has just been issued; it is entitled "How to Avoid Contracting Tuberculosis." It contains much good advice, and is based upon the scientific demonstration of the contagious character of the disease, upon which, the members of the Society evidently believe it is impossible to lay too much stress, and they have very little to say about "predisposition" or "the pre-tubercular stage," which we used to hear so much about.

The Board of Commissioners of Public Charities of the State of Pennsylvania has just issued its twenty-second annual report, in a handsome octavo volume, covering its operations during the year 1891. The beneficent influence of this board can scarcely be estimated. Its work will perhaps be best shown by a few extracts from the last report. During the year all the hospitals, alms-houses, and insane asylums in the State were visited, and the board reports that "in many of the hospitals, homes and almshouses, we were gratified to see that improved general government prevailed, and that many of the suggestions made by us in regard to the care and treatment of the inmates had been introduced by the managers and officers of the institutions.

"Most of the jails of the State have been visited during the past year. Those under the management of inspectors and wardens were found to be in good condition, and the laws for their government were generally enforced. Those under the care of the sheriffs, on the other hand, were, as usual, for the most part in bad condition. Indeed, they remained much the same as we found them years ago—schools of vice for the uninitiated young inmates who were there for their first offense. We believe that no improvement can be made in these prisons until they are placed under the control of inspectors, and are entirely removed from that of the sheriffs.

"Owing to a change made in the law regulating immigration, our duty, as United States Commissioners of Immigration, has ceased.

"We began the work on November 7, 1882, and from that time until August 31, 1891, when our services ended, 265,274 persons arrived at the Port of Philadelphia from foreign ports and were examined and inspected by our officers.

"In order to obtain reliable information as to whether any of the immigrants who landed at this port during the year ending June 30, 1891, and if so, how many, were admitted into any almshouse in Pennsylvania, an interrogatory circular, with blank, was sent to each institution, asking for an account of the number thus admitted. Returns were reviewed from all the alms-houses of the State (seventy-two in number), and they showed that not one immigrant who had landed at this port during said year had been admitted to an almshouse to become a charge upon the public."

This is a strong argument, if any were needed, to defend the laws now in operation against pauper immigration.

The Lunacy Committee of the State Board of Public Charities has done good work in having insane paupers removed that were detained in almshouses or in private custody, wherever they did not receive proper care, and transferred to the State hospitals for the insane. The Committee has turned its attention to the insane prisoners; and the Eastern Penitentiary is now under fire for confining an alleged lunatic convict in a bed and otherwise maltreating him because the wardens thought that he was shamming. As a result it is hoped that provision will soon be made for the establishment of an institution for the treatment of the criminal insane and insane criminals for whom the ordinary facilities in our hospitals are inadequate and unsuitable.

The medical schools are all in operation for the winter course. Each one reports improved accommodations and increased classes, and claims that everything points to a prosperous year. At the Woman's Medical College there have been added a capacious quiz room, a new library and reading room, and a comfortable lunch room; the chemical, physiological, histological and pathological laboratories have been enlarged, and new outfits provided, including additional microscopes. The anatomical and operative surgery rooms have had their ventilation improved and electric lights have been introduced. The next years' class, in the fall of 1893, will inaugurate the obligatory four years' course at this college. The University of Pennsylvania has also lengthened its course beginning with the session of 1893—4; the fourth year, which at present is voluntary, will become obligatory. All the medical schools of Philadelphia now require entrance examinations, have graded courses, and three years' attendance upon lectures, with annual examinations, and recommend a fourth year which at present is voluntary.

At the Polyclinic, Dr. John B. Roberts delivered the Introductory Address this year. He commented upon the success of this institution, and said that "the establishment of special colleges for practical work in medicine, adapted to the needs of practitioners, is an American idea. Great has been the success attending this effort to bring physicians into actual contact with patients in such manner that they may make practical study of disease under the direction of other physicians. The latter, while acting in a certain sense as teachers, are in reality only brother practitioners, similarly engaged in observing and studying nature's pathological processes. This community of interest and work makes our relation with those who come to the Philadelphia Polyclinic as pupil-physicians a very enjoyable one. The man, from a distant part of this country or from a foreign land, brings his experience and judgment to bear on the cases presented, and may aid much in unravelling knotty points that seem inexplicable to us, who have gained our experience here among different people and in dissimilar climatic surroundings. Thus it is that in my department the clinic hour sometimes becomes a sort of consultation in which I gain important hints.

"The benefit to be derived by the pupil is like that obtained by the boy in the manual training school or by the student in the laboratory. In fact, a polyclinic, where the classes are kept small, is what might be termed a 'clinical laboratory;' for in it the pupil-physicians handle broken limbs, tie arteries, chisel bones, make laryngeal applications, fit spectacles, and do themselves what, as students, they saw the professors do; sometimes indeed only by the use of an opera-glass.

"These manipulations must be done constantly by every man who wishes to be competent; for it is unfamiliarity that makes a workman timid, non-reliant and unsuccessful. The trained ear, eye, finger and hand are only obtained by the practice which takes away conscious effort. Many physicians of limited success and slender income owe their mediocrity to the absence of opportunity to become familiar with the many variations and phases of disease and injury.

"A doctor, to become experienced, must see and touch very many patients. This can only be done in a limited period of time by dispensary or hospital work in large cities; hence those who have no such opportunity because of residence, or other militating circumstances, must come to a post-graduate school, or else wait so many years for private practice to furnish enough cases that the experience, when gained, can only be enjoyed in old age.

"The Philadelphia Polyclinic is a clinical laboratory where the pupil uses his own brains and hands as in private practice; but here he sees in six weeks as much as, if not more than he would in the first six years of private practice. Another advantage is the direction to his observation and experience supplied by association with men who, as specialists, have given years to the study of a single department of medicine.

"It affords me pleasure to tell you that we can offer you better facilities than any of your predecessors have had here. Our surgical dispensary has outgrown its quarters, and the Trustees are about to make alterations to accommodate the increasingly large daily clinic. The number of gynecological and surgical operations is greater than ever, while the attendance of patients with eye, ear and throat difficulties offers unusual facilities for personal study. About 10,000 new cases per annum in the dispensary, and about 400 new cases admitted to the wards during the year, give the teachers a wide field for instruction. To this we add, as you know, many opportunities in the general and surgical hospitals of the city with which members of the medical staff are connected.

"The elaborate course of lectures to nurses in the Training School of the Polyclinic Hospital are open to the pupil physicians free of charge. By attendance on these, practitioners can gain many hints valuable to them in training nurses in their own localities."

The remainder of Dr. Roberts' address was devoted to "Diseases and Injuries of the Hip-joint," illustrated with diagrams and specimens.

The faculty of the Polyclinic has recently begun the publication of a medical journal filled with practical articles by the medical staff.

A patient was recently admitted who had attempted suicide by shooting himself in the ear. He spat, it is said, a portion of the bullet out of his mouth; the remainder was subsequently removed from his ear by Dr. Randall.

Dr. Roberts has recently tried infusion of salt solution into the veins of the arm, after shock from railroad crush. He recently ligated before the pupils the internal carotid artery, which was wounded in extirpation of a deep cervical tumor. The patient died subsequently with brain symptoms.

At the last meeting of the Philadelphia County Medical Society, Dr. Barton Cooke Hirst reported a case of symphyseotomy at the University Maternity Hospital, upon a young German woman with a kyphotic pelvis. The operation was readily done, and a live infant, a girl of normal development, was promptly delivered. The mother bore the operation well, and the infant's life was saved, which is a better result than could be obtained by craniotomy and not less good than Cæsarean section. It is believed that this case is the first in the United States in which symphyseotomy was performed as a substitute for the more grave Cæsarean operation, and its results warrant the hope that it may be found an efficient substitute for the latter, in appropriate cases.

At the suit of the Society for the Prevention of Cruelty to Animals, Dr. Wm. M. Zuill, a professor in the Veterinary Department of the University of Pennsylvania, was fined by a magistrate $20 for "docking" the tail of a carriage horse by request of the owner. It was in evidence that the horse was extremely sensitive, and that only about five inches of the tail was removed in order to keep the caudal appendage from injury by striking against the dash-board. This operation was not "docking," said the veterinarian. "Docking," he said, means the cutting off about a foot of the tail, leaving it the fashionable length, seven inches. A number of physicians from the Veterinary Department of the University of Pennsylvania testified that when such a small portion of the tail is removed the pain of the operation is but trifling, and in this case was not cruel, but necessary for the relief of the animal. The case will be taken to court on an appeal by Dr. Zuill.

The vacancy at the University of Pennsylvania caused by the death of Dr. Formad, who was demonstrator of morbid anatomy and lecturer on experimental pathology, has been filled by dividing the duties between Dr. Joseph McFarland, who has taken charge of pathological histology with [illegible]ology and bacteriology; while the teaching of morbid anatomy and the performance of autopsies has been awarded to Dr. Henry W. Cattell.

Prof. John J. Reese died on the 4th of September at Atlantic City, aged 74 years. As a lecturer and teacher of toxicology and writer upon medico-legal topics he was widely known. Personally he was highly esteemed and had a large circle of friends. He was graduated at the Art Department of the University of Pennsylvania in 1836, and in 1839 from the Medical Department, receiving at the same time the degree of Master of Arts. He was President of the Medical Jurisprudence Society in 1866–67. In 1854, he was appointed professor of medical chemistry in the old Pennsylvania College, and served for five years. In 1865, he was elected to the chair of toxicology and medical jurisprudence in the University of Pennsylvania, which he still held at the time of his death. He was the author of several manuals, but his best known work is his text-book on medical jurisprudence and toxicology. He also edited the seventh American edition of Taylor's Medical Jurisprudence.

Women's Medical College of Baltimore.

To the Editor of the Journal of the American Medical Association:

In commencing the instruction in Latin of the students of the Woman's Medical College of this city, I gave the following reasons why as medical students they should acquire a knowledge of that language. I am glad to say that all the students of the college except three or four, and they having previously studied it elsewhere, have joined the class.

1. Because though called a "dead" language, and although not now spoken by any nation, it is not really dead, but flourishes with a perennial and ever increasing vigor.

2. Because of its wide and far-reaching influence on the structure and development of the languages of all civilized nations, especially those of Southern Europe.

3. Because the resources of our language do not suffice for the constantly needed new supply of words, for which we are compelled to resort to the "classics."

4. Because we cannot dispense, if we would, with the Latin that has been incorporated into our own language.

5. Because science and medicine are full of Latin terms and others are being constantly added to our scientific vocabulary.

6. Because of the aid it affords to the study of science and medicine and to the knowledge of the source and meaning of words.

7. Because even an elementary and imperfect knowledge of Latin will afford great assistance in your medical studies.

8. Because the study of Latin disciplines the mind, promotes habits of thought and attention, elevates the sentiments, imparts a scholarly tone, and furnishes one with noble examples, grand ideas and a magnificent literature.

9. Because no translation affords an adequate conception of the great classical authors, and besides if it did scarcely anyone would ever read it. Thus those who do not study the language itself are virtually cut off from all its benefits.

10. Because a classical and literary training is the most important preparation for the medical career.

11. Because a very respectable knowledge of Latin can be acquired at very little cost of time and study, perseverance being the chief element of success in its acquisition.

12. Because its requirement is in the line of elevation of the medical standard, and consequently of the standing of the medical profession.

13. Because this college in common with all respectable American medical colleges now requires it as a part of its preliminary requirements, in conformity with the regulations of the American Medical College Association.

14. Because, for the new students, the forms of its requirement are most liberal and accommodating, a year being allowed for preparation.

11. Because through the liberality of our Faculty the opportunity of acquirement is offered to all of you—whether first, second, third, or fourth year students, free of cost.

Eugene F. Cordell, M.D.

Baltimore. Oct. 18, 1892.

To the Editor of the Journal of the American Medical Association:

Having received favorable responses to a letter addressed to all Southern Medical Colleges, we are authorized by them to say that a convention of their representatives will be held in Louisville, Ky., November 16, 1892, for the purpose of considering the question of a higher standard of medical education.

Yours fraternally,
W. T. Briggs,
G. C. Savage.

NECROLOGY.

Dr. John James Reese, of the University of Pennsylvania, died at Atlantic City, early in September. He was a toxicologist of national reputation, and had been identified with jurisprudential medicine and the University since 1865. He retired to an emeritus professorship in October of last year. He was the American editor of Taylor's seventh edition of the standard treatise on Medical Jurisprudence. He also published a college text-book or Manual of Toxicology, also an analysis of Physiology. In 1861, he served the Government as surgeon of volunteers, and was put in charge of the United States Hospital on Christian street, Philadelphia. He became the visiting physician to St. Joseph's Hospital and two or more other charitable institutions. He was in his seventy-fifth year at the time of his demise; he first joined the American Medical Association early in the fifties.

Dr. James Henry Steuart, of Baltimore, died October 8, in the fifty-eighth year of his age. He was a native of that city, son of the late Gen. George H. Steuart. He was a graduate of Princeton College in 1855, and of the medical department of Maryland University two years later. "He leaves behind him a monument in the gratitude and love of those to whom his high life and labors were a blessing and an example." His final illness was one of prolonged and patient suffering. A widow and three children survive him.

BOOK REVIEWS.

The Legends of Alaska. By Prof. Bushrod W. James, M. D. Porter & Coates, Publishers, Philadelphia.

This exceedingly attractive little volume gives us a glimpse into the peculiarities of the people of Alaska, as well as the natural resources of wealth that are found in that portion of our Nation's domain. The book is made all the more readable by reason of its being written in the style of Hiawatha.

Simple Water Test.—Into a ground glass stoppered, perfectly clean bottle put five ounces of the water to be tested. To the water add ten grains of pure, granulated, white sugar. Cork tight, and set in a window exposed freely to light but not to direct rays of the sun. Do not disturb the bottle, and keep the temperature as near 70° F. as possible. If the water contains organic matter, within forty-eight hours, an abundance of whitish specks will be seen floating about, and the more organic matter the more specks. In a week or ten days, if the water is very bad, the odor of rancid butter will be noticed on removing the stopper. The little specks will settle to the bottom, where they appear as white flocculent masses. Such water should not be used for potable purposes.

MISCELLANY.

The Southern Surgical and Gynecological Association will hold its fifth annual meeting in the city of Louisville, Tuesday, Wednesday and Thursday, November 15, 16 and 17, 1892, under the presidency of Dr. J. McF. Gaston, of Atlanta. Members of the medical profession are cordially invited to attend. The following papers will be read:

The President's Annual Address, J. McFadden Gaston, M.D., Atlanta, Ga.

Cervicitis, Bedford Brown, M.D., Alexandria, Va.

Surgical Treatment of Endometritis, A. Vander Veer, M.D., Albany, N. Y.

Experiences in Pelvic Surgery, A. V. L. Brokaw, M.D., St. Louis, Mo.

Craniotomy upon the Living Fœtus is not Justifiable, Cornelius Kollock, M.D., Cheraw, S. C.

A Case of Extensive Hematocele Resulting from Tubal Pregnancy Rupturing into the Broad Ligament, W. D. Haggard, M.D., Nashville, Tenn.

Fibroid Tumor of Uterus—Pregnancy—Rupture at Fourth Month—Operation Six Weeks afterwards—Death, S. M. Hogan, M.D., Union Springs, Ala.

A Contribution to the Study of Abdominal Pregnancy, H. C. Coe, M.D., New York City.

Tubal Pregnancy, Joseph Price, M.D., Philadelphia, Pa.

Some Kidney Operations, with Remarks, Geo. Ben. Johnston, M.D., Richmond, Va.

Surgical Treatment of Inguinal Hernia in the Male, Henry O. Marcy, M.D., Boston, Mass.

The Symptoms of Fractures—Their Importance and Significance, W. C. Dugan, M.D., Louisville, Ky.

The Part that Rectal Diseases play in Women, J. M. Mathews, M.D., Louisville, Ky.

Poisoning by the Bite of the Southern Spider, J. T. Wilson, M.D., Sherman, Texas.

A Plea for More Rapid Surgical Work, Ap Morgan Vance, M.D., Louisville, Ky.

Specialism as Related to the Practice of Gynecology, Wm. Warren Potter, M.D., Buffalo, N. Y.

The Relation of the General Practitioner to Gynecology, R. M. Cunningham, M.D., Birmingham, Ala.

Morphology of Abdominal Tumors, Howard A. Kelly, M.D., Baltimore, Md.

Modern Researches in Relation to the Surgery of the Genito-Urinary Organs, G. Frank Lydston, M.D., Chicago, Ill.

Amputation of Breast for Malignant Disease, H. Horace Grant, M.D., Louisville, Ky.

Fecal and Other Fistulæ Following Abdominal Section, Joseph Taber Johnson, M.D., Washington, D. C.

Nature of Shock and Allied Conditions, Wm. C. Dabney, M.D., University of Virginia.

The Present Status of Drainage in Surgery, A. Morgan Cartledge, M.D., Louisville, Ky.

Cholecystotomy, *with the Report of a Case, Edwin Ricketts,* M.D., Cincinnati, Ohio.

Treatment of Stones in the Biliary Ducts, W. E. B. Davis, M.D., Birmingham, Ala.

Personal Recollections of Dr. Benjamin W. Dudley and his Surgical Methods, Bedford Brown, M.D., Alexandria, Va.

Intestinal Anastomosis without Mechanical Devices—Circulo-Lateral Enterorrhaphy, J. D. S. Davis, M.D., Birmingham, Ala.

(Title of paper not determined), Geo. H. Noble, M.D., Atlanta, Ga.

(Title of paper not determined), W. L. Robinson, M.D., Danville, Va.

(Title of paper not determined), W. Gill Wylie, M.D., New York City.

J. McFadden Gaston, M.D., *President.*

W. E. B. Davis, M.D., *Secretary.*

New York State Association of Railway Surgeons.—The second annual meeting will be held in the Academy of Medicine, 17 W. Forty-third St., New York City, Monday, November 14, 1892. The following papers will be read:

1. Conservative Surgery as Applied to Railway Injuries, Dr. R. S. Harnden, of Waverly. Discussion opened by Dr. L. S. Pilcher, of Brooklyn.
2. A Contribution to the Study of Amputations at the Hip-joint, Dr. J. B. Murdock, of Pittsburg. Discussion opened by Dr. John A. Wyeth, of New York.
3. Osteogenesis and Osteoplasty in Crushing Lesions of the Extremities, Dr. Thomas H. Manley, of New York. Discussion opened by Dr. Robert F. Weir, of New York.
4. President's Address.
5. Expert Examination and Testimony in Railway Cases, Dr. B. A. Watson, of Jersey City. Discussion opened by Dr. Stephen Smith, of New York.
6. *The Transportation of the Wounded upon Railways,* Dr. W. B. Outten, of St. Louis. Discussion opened by Dr. J. W. Galbraith, of Omaha.
7. Calendula as a Surgical Dressing, Dr. A. Wilson Dods, of Ferdonia.

Official List of Changes *in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from October 14, 1892, to October 20, 1892.*

First Lieut. Samuel R. Dunlop, Asst. Surgeon, leave of absence granted is extended one month.

Major Johnson V. D. Middleton, Surgeon U. S. A., is granted leave of absence for one month, to take effect upon his relief from duty at Ft. Columbus, N. Y.

First Lieut. Allen M. Smith, Asst. Surgeon U. S. A., is relieved from further duty at Ft. Yellowstone, Wyo., and will proceed to Ft. Custer, Mont., and report to the commanding officer of that post for temporary duty.

Lieut.-Col. Charles R. Greenleaf, Deputy Surgeon-General, *is appointed member of a board of officers, to meet at* Helena, Mont., on the 1st day of November, 1892, or as soon thereafter as practicable, for the purpose of selecting a site for a military post at that place, as provided for under an Act of Congress approved May 12, 1892, entitled "An Act to establish a military post at or near the city of Helena, in Lewis and Clarke County, in the State of Montana."

Official List of Changes in the Medical Corps of the U. S. Navy, for the Week Ending October 22, 1892.

Asst. Surgeon L. W. Spratling, ordered to receiving ship "St. Louis."

Asst. Surgeon Lewis Morris, from receiving ship "St. Louis," and to the U. S. S. "Monocacy."

Asst. Surgeon George Rothganger, from the U. S. S. "Monocacy," and ordered to proceed home.

Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Three Weeks Ending October 15, 1892.

Surgeon George Purviance, granted leave of absence for seven days. October 12, 1892

P. A. Surgeon C. E. Banks, to rejoin station at Portland, Me. October 14, 1892.

P. A. Surgeon S. C. Devan, ordered to Washington, D. C., for special duty. September 29, 1892.

P. A. Surgeon P. C. Kalloch, to rejoin station at Boston, Mass. *October 14, 1892.*

P. A. Surgeon Eugene Wasdin, to rejoin station at Charleston, S. C. October 3, 1892.

Asst. Surgeon W. P. McIntosh, to proceed to Buffalo, N. Y., for temporary duty, September 25, 1892. To proceed to Ellis Island for temporary duty, September 30, 1892. To report in person to the Supervising Surgeon-General, October 8, 1892. To rejoin station at New Orleans, La., October 10, 1892.

P. A. Surgeon W. J. Pettus, to proceed to New York, N. Y., for temporary duty. September 25, 1892.

P. A. Surgeon G. M. Magruder, to proceed to Tacoma, Wash., for special duty. October 7, 1892.

P. A. Surgeon J. O. Cobb, to rejoin station at Detroit, Mich. October 7, 1892.

P. A. Surgeon J. B. Stoner, to rejoin station at Pittsburgh, Pa., October 3, 1892. Granted leave of absence for seven days. October 4, 1892.

Asst. Surgeon M. J. Rosenau, relieved from duty at Cape Charles Quarantine, October 11, 1892. Granted leave of absence for thirty days. October 13, 1892.

Asst. Surgeon L. E. Cofer, granted leave of absence for three months on account of sickness. October 15, 1892.

Asst. Surgeon C. H. Gardner, to report to the medical officer in command, San Francisco, Cal., for duty. October 12, 1892.

ORIGINAL ARTICLES.

THE TREATMENT OF CATARRHAL DISEASES OF THE UPPER AIR PASSAGES.

Read before the Section of Laryngology and Otology, at the Forty-third Annual meeting of the American Medical Association, held at Detroit, June, 1892.

BY NORVAL H. PIERCE, M.D.,
SURGEON TO THE NOSE AND THROAT CLINIC, MICHAEL REESE HOSPITAL, *OUT-DOOR DEPARTMENT, CHICAGO, ILL.*

I pray you bear with me if, in the beginning of this paper, I present a matter which may at first seem irrelevant to the subject. My excuse is three-fold: First, that the condition referred to is frequently a cause of nasal and laryngeal disease; second, that it is of frequent occurrence; third, that its importance is often overlooked. I refer in this to the inspiratory collapse of the alæ nasi in persons enjoying fair health—a sucking in of wings of the nose at each inspiration. I say in fair health to distinguish the same phenomenon as it occurs *in extremis.*

The literature on the subject is peculiarly scant. Traube describes a case occurring during pneumonia and one in paralysis ascendans; B. Frankel, in a child suffering from meningitis. In Traube's cases the hinderance to air was so great that he employed a hair pin held in place by means of adhesive plaster to overcome it. Frankel employed an ear speculum. Drayton (*Med. Record*, Dec. 15, 1888) reports a cure in the case of a pupil in vocal culture by means of a cotton pledget and message. Zeim also reports a case. Latterly I am not aware of any additions to the subject, with the exception of the masterly contribution by Mortz Schmidt (*Ueber das Ansaugen der Nasenfugel, Deutche Mediscinischer Wochenschrift*, No. 4, 1892), to whom I owe much of my knowledge of this condition. He accounts for the scant observations on the subject by the fact that we are accustomed to at once introduce the nasal speculum in beginning our examinations without at first observing the alæ of the nose. We have, however, only to request our patients to take a full breath before introducing the speculum to find how frequently this condition, in a greater or less degree, occurs, and that a convergence which furnishes an absolute hinderance to the full respiratory act is not by any means seldom, in which cases the patients express relief if the alæ are simply held outward with the fingers.

The condition is made still worse when there exists at the same time a deviation of the septum cartilgineum. The convergence includes the entire alæ as in facial paralysis, or only the plica vestibuli. The former occurs most frequently in those of a dolichocephalic type, the latter in the brachycephalic.

The cause of this condition is to be found in an atonic condition of the nasal wall from loss of function of the musculi-dilatores et lavatores alæ nasi. This weakness is in turn caused by all those long continued conditions which setting in at an early age interfere with nasal respiration, whereby the muscles have not sufficient exercise. Adenoid vegetations are a prominent cause of this.

Now as to the philosophy of this in connection with nasal or laryngeal diseases. We must first understand that the beginning of the respiratory track is at the entrance of the nose and not at the larynx; and that behind every constricted point in the entire track from the entrance of the nose to the finest alveoli there is a rarefaction of air during every inspiration. The degree of rarefaction varies in ratio, to the extent of the constriction and the force of inspiration. The natural effect of this rarefaction is a suction which is exerted upon the blood within the domain of such rarefaction, and which is made manifest to us by a local hyperæmia of the mucous membrane and consequent excessive secretion.

Respiratory convergence of the wings of the nose may give rise to nearly all the phenomena arising from contraction of any other part of the respiratory tract, migraine, aprosexia, asthma, etc. Usually the influence is exerted directly on the mucous membrane of the nose, cavum or pharynx, producing redness, swelling of the mucous membrane, and increased secretion of mucus. Tinnitis aurium is not infrequently caused by congestion of the mucous membrane lining of the cavum, which congestion, if dependent upon convergence of the alæ of the nose, may be relieved by preventing the latter condition. It is true that the conditions of the mucous membrane enumerated may have existed for so long a time that they may require direct treatment, but I have relieved some troublesome cases with swelling of the turbinated bodies accompanied by secretion, headache, etc., by means of the simple but eminently effective instrument which I will now speak about.

The treatment is simple. Schmidt has tried gymnastics of the nasal muscles, but has given it up as unsatisfactory. He has used the Feldbaush tubes for a long time with satisfactory results, but they cause a certain amount of irritation from pressure on the septum. Feldbausch, on the suggestion of Schmidt, has produced the instrument which I hold in my hand and which is quite satisfactory. They are of course made in different sizes to fit different noses. It is held in place by introducing the heads from behind into the pocket at the end of the nose, when the spring is pressed up against the alæ of the nose, the connecting part resting on the septum cutaneum.

Acute Rhinitis.—During the trying weather of the past winter we have had ample opportunity of treating coryza. The symptoms have not varied from the well known ones of slight pyrexia, lassitude, chilliness, frontal headache, blocking up of the nose, with swelling of the mucous membrane, hypersecretion, etc. The treatment which we have employed has proven most satisfactory. Internally we have given large doses of bromides, or a tablet compounded after the formula of Dr. Lincoln, consisting of camphor, gr. $\frac{1}{4}$, fluid ex. belladonna gr. $\frac{1}{8}$, quin. sulph. gr. $\frac{1}{4}$, one every hour. The local application by means of the cotton carrier of cocaine dissolved in tinct. belladonna in from three to five per cent. solution has been especially useful in immediately relieving the most prominent symptoms,*i.e.*,turgesence of the mucous membrane, frontal headache, and throbbing in the nose. We believe that such treatment shortens the duration of all cases of coryza and in some cases seems really to abort the attack. If there is a predisposition against cocaine we may use tinct. belladonna, alone applied on the cotton carrier. We have not lost sight of the fact that chronic rhinitis in the beginning results from relapsing acute attacks and have retained the patients under observation until the turbinated bodies returned to a normal condition.

For this purpose we have used nearly the same treatment as that employed in simple chronic rhinitis. In this the most prominent position is given to the nasal bath. The ingredients used and the mode of employment are simple and effective. A half teaspoonful of salt and a half teaspoonful of glycerine are dissolved in half a glass of warm water.

Take a teaspoonful of this mixture, rest the point of the spoon on the lower part of the nostril, slowly throw the head backward, saying at the same time a continuous "ah," and allowing the fluid to gently run into the nose. Then incline the head forward and the fluid will run out. Repeat this in each nostril three or more times night and morning. The sodium chloride has a soothing effect upon the mucous membrane; the glycerine a mildly depleting action; the water is cleansing. I have lately had constructed a glass receptacle in the shape of a covered spoon having a spout which faciliates the taking of the bath. Douches are never allowed in any form of simple chronic rhinitis. Not because we believe they are potent in causing disease of the middle ear but because of their local effect on the turbinated bodies. We are convinced that they increase rather than diminish the hyperemia present in simple chronic catarrh and that they aid the hypertrophic process toward which simple chronic rhinitis has always a strong tendency. Very frequently the nasal bath is all the treatment required. In other cases it may be necessary to use sozo iodide of zinc in sugar of milk, $\frac{1}{10}$; this especially in catarrh of the cavum where decomposition of secretion is very liable to occur. Or we may use menthol dissolved in iodine in from two to ten per cent.solution where turgescence and the nervous symptoms predominate, or peroxide of hydrogen when the purulent features are most prominent as is the case especially in the rhinites of children. Thymol is also a most useful agent in certain cases where the discharges are liable to become inspissated. We have almost done away with aqueous sprays in the treatment of nasal diseases because of the mechanical irritation caused by the extreme force with which they strike the parts to be treated, using instead one or the other of the petroleum vehicles.

There has lately been brought before the profession by the chemists, McKesson & Robbins, a preparation of stearic acid and zinc which to my thinking bids fair to become a valuable addition to our armamentarium. In the manufacture of this new excipient stearic acid, prepared from suet, is used. When a soluble salt of zinc is added to this acid a light mollescent precipitate results resembling in its extreme lightness calcinated magnesia. Various medicinal agents are combined with this powder, such as tanic, boric, salicylic acids, balsam peru, aristol, ichthyol, menthol, and many others. One of the chief advantages of this preparation is its power of adhering to the surface upon which it is placed. Rubbed on the palm of the hand it is absolutely unaffected by the addition of water—the latter acting as quicksilver does, and when poured off not the slightest moisture remains. It is said to remain in place on the urethral mucous membrane for from six to twenty-four hours regardless of the passing secretions. Another important feature is its freedom from the formation of the little balls which has rendered the use of insufflations in the past more harmful than beneficial. Further experience with these preparations must be had before a conclusive opinion may be stated but at present we are most favorably impressed. In the pharyngitis which so often accompanies chronic rhinitis, where the mucous membrane is coated over with a tenaceous, glary layer of partially inspissated mucus, we first cleanse the parts by wiping with a cotton pledget until the secretion is entirely removed; then a five to ten per cent. solution of nitrate of silver is applied by means of a spray. The conditions which were first designated by Schmidt of Frankfort-on-Main, "bilateral pharyngitis," and which is so frequent in singers, is, in our experience, best treated by cauterizing the red granular streaks which stretch up along the lateral pharyngeal walls with mitigated lapis over their entire extent even up into the Rosenmuller's groove if need be. The results of this procedure, especially in vocalists, are often remarkable. The voice is improved and the disagreeable tickling sensation immediately removed. In catarrh of the crypts of Liuschka's tonsil the following operation is performed. After thorough cocainization of the palate, pillars, pharynx, and post nasal space, the palate is hooked back by means of a palatal retractor. I am accustomed to the one figured below and which is quite practical. After this the tongue is depressed by a large, short handled mirror and held so that the crypts of the tonsils can be seen in the mirror at the same time that the tongue is being depressed. A probe bent at a proper curvature, and having mitigated lapis fused in its head is then carried up into the crypts of the tonsils which are thoroughly cauterized. In this way much of the dropping of mucus so frequently complained of may be immediately arrested, and which may evade all other modes of treatment.

In hypertrophic rhinitis there is no time lost in any method of treatment other than the cold or electric snare, or the electric cautery. The results of this treatment are so much more satisfactory and permanent than those obtained by the use of chromic acid, acetic acid, etc., that the two methods in our opinion are not to be compared.

In circumscribed anterior hypertrophies the cold or electric snare is used. In the electric snare ordinary piano wire No. 8 is employed instead of platinum. The piano wire has greater mechanical and less electrical resistance and the former point is one of great practical value in snaring post nasal hypertrophies. When a turbinated body is hypertrophic along its entire length we draw three lines of cauterization from behind forward with the knife shaped point, one above, one below, and one in the middle. I find that the results are much enhanced if the furrows thus burned are then carefully rubbed over with a crystal of trichloretic acid. The reaction after such an application instead of being more severe, is less, and the relief of obstruction thus obtained instead of lasting for only a year or a year and a half as is often the case when the cautery alone is used, is nearly always permanent.

Atrophic Rhinitis.—It has been my fate, it seems to me, to have to deal with more than my share of this disease. It commenced while at work in Chiari's Clinic in Vienna, when he portioned out to me six cases to be treated by Braun's vibratory massage. Instead of trying to dodge such a fate I have yielded and given the subject a good deal of careful attention. I will be as terse as possible in my description of the treatment which I have found most beneficial. It is an open question in my mind as to whether or not the fears of the douche causing ear trouble is well founded or not. I am aware that we have strong authority for such fears and such ones as Roose, Mackenzie, etc., are not to be ignored. Still, and it may be that my experience has been peculiarly happy, there have come to me no untoward effects from this valuable therapeutic agent, with the one exception of a man who in my presence deliberately turned his head to one side while taking a douch. At least I have my patients who are suffering with fœtid rhinitis take a douch once or twice in a day, but only in this disease is it ever used. I have the directions plainly printed on a slip which the patient takes away with him.

First let me digress long enough to say that after thoroughly testing Braun's vibratory massage in the Vienna Clinics I gave the results in a paper which I read last year before this Section. One of my conclusions therein was that to the cleanlinesss which is so essentially a part of this mode of treatment is due most of the speedy relief of disagreeable symptoms, fœtid secretions, etc. Braun claimed that under his method the atrophic turbinated bodies returned to the natural proportions. My experience has not substantiated this latter statement. During the past year I have modified Braun's methods in the following manner: The patient comes to me daily. A piece of absorbent cotton loosely pulled from the roll is torn to a size which will completely but loosely fit the inferior meatus and space included between the middle of the inferior turbinated body and septum. This *dry* cotton is held in the accompanying instrument, and the vibratory movements carried over the inferior, middle and superior turbinated bodies, pharynx (as far as possible), septum and floor of the nose. From three to six pledgets of cotton may be necessary in each nostril to entirely bring away the discharge, scabs, etc. Allow me to accent the fact that the cotton is dry, as I believe this dry method distinctly superior in its results to the moist method as recommended by Braun. This absolute cleanliness cannot be too strongly insisted on. On examination after this massage the mucous membrane looks pink and clean, and the patient often expresses a feeling of comfortable warmth and relief. Immediately afterwards we may use balsam peru, 10 per cent., iodo-glycerine, thymol in albolene, or any of the many good things recommended for the disease provided they are not too irritating. But I am convinced that the vibratory massage carried forth as above described has a distinct worth, and will shorten the treatment of fœtid rhinitis by many months.

I had intended to speak further on the treatment of simple laryngeal inflammation, especially as it occurs in singers, but I fear that I have had more than my share of time.

I have intentionally refrained from speaking of deflective septum in connection with rhinitis, as it would lead me into too vast a field,

In conclusion I would say that there are few cases that do not require constitutional treatment,

Rheumatism or the rheumatic diathesis, plethora, scrofula and alcoholism should be carefully watched for and treated according to the well known lines. We cannot cry out too loudly against smoking as a cause in many individuals of disease of the upper air tracts. Especially harmful are cigarettes, because the smoke from them is inhaled and this causes atrophy of the vocal cords. A recent case of this kind vividly brought the effect of cigarette smoke to my notice. An actor after two years of excessive cigarette smoking applied to me for an increasing loss of vocal resonance and timbre with recurring attacks of hoarseness. I found the vocal cords atrophied to two thirds their former size. I had examined them when they were normal.

MENTAL ABERRATION ATTENDING HYPERTROPHIC RHINITIS, WITH SUB-ACUTE OTITIS MEDIA.

Read in the Section of Laryngology and Otology, at the Forty-third annual meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY J. G. CARPENTER, M.D.,
OF STANFORD, KY.
President Central Kentucky Medical Society; Member of the Kentucky State Medical Society; Fellow and Organizer of the American Rhinological Association; Member Mississippi Valley Medical Society; Permanent Member American Medical Association.

Mental aberration attending intra-nasal affections and their sequelæ is considered rare by the profession; yet, it has been the experience and observation of many of the Fellows of the American Rhinological Association, that mental aberration, or insanity *per se*, has appeared upon the existing intra nasal disease, that removal of the latter often causes the former to subside.

Roosa gives, in his valuable books on "Diseases of Ear," a case of insanity and suicide, on account of tinnitus aurium. Experienced rhinologists can recall one or more cases of mental aberration due to intra-nasal disease. In fact, so much importance is attached to disease of the upper air passages, being the *fons et origo*, of mental aberration, that a committee was appointed, consisting of Fellows of the American Rhinological Association to examine inmates of State Insane Asylums, and ascertain the per cent. of patients affected with disease of upper air passages.

While consent has been given by the Superintendents to make the rhino-pharyngoscopic examinations, the committee has not yet reported, owing to the difficulty in getting the insane to submit to the necessary investigation.

It has been the common experience of practical and experienced rhinologists to almost daily have patients with *impaired intellectuality, the mind* going into vacuity, the lawyer or speaker losing the thread of argument, the accountant making egregious blunders in his addition, another unable to concentrate his mind to read an interesting chapter or column or carry on a spirited conversation; another *will hear an interesting discourse* or enjoy a thrilling article, yet unable to give the salient points presented, is neglectful, absent-minded. A prominent farmer, in settling with his tenants, made numerous blunders, making mistakes in dollars and cents, as often against as for self. Is sad and despondent, very melancholic thinks he is losing his mind. A prominent merchant often fails to charge merchandise sold, or recharges the second or third time, or fails to enter the credits, is not dishonest and suffers much mortification on finding the stupendous errors, is irritable, easily insulted, has presentiment of sudden death, feels that he is losing his mind, is quite emotional. A young lady of good social position thinks herself unclean, unfit to keep company with her mother, sisters, sees numerous imaginary unclean spots on her dress and clothing, is morose, seeks solitude, is melancholic, says she will be lost on account of her sins, is often found walking the porch or kitchen in night clothes in midwinter, or wandering in this nude state out in the yard; she had been formerly quite anæmic, had retroversion and catarrhal endometritis, and with proper treatment, the latter was cured, but the mental aberration continued and was cured by treatment directed to the naso-pharynx and galvaniztion. Another patient, married lady, with chronic rhinitis, becomes intensely sick, excited, emotional, and has fear of impending death; sheds tears freely on going to church or to any public gathering; is despondent and seeks solitude. Treatment directed to the upper air passage and galvanism effect a cure. Another patient, a maiden, has been afflicted with symptoms enumerated in the last case, *is afraid to be left alone,* sleep by herself, or sleep in a dark room; at night, keeps the lamp burning brightly, the window shutters open, the window blind up so that she may see any burglars who might chance to disturb her quietude; she has insomnia, has the most intense aversion to her family, afraid of her uncles and aunts, seeks solitude; will not be seen by friends or strangers, has constant presentiment of death and other evil omen; only through force, will she leave her house; has violent headaches, highly emotional, brings forth tears in abundance, is suspicious of mother and sister, has many delusions. *Treatment directed to* upper air passages, nerve tonics, galvanism and proper attention to retroversion effected a cure.

Mrs. —, age, 35 years, former health good, family history excellent, has had hypertrophic *rhinitis for* years, nasal occlusion, though a woman of strong mind and body, is quite emotional, subjected to any great excitement or bad news, develops the tetanoid state; is given to frequent shedding of tears, seeks solitude, is melancholic; is restored to health by cauterizing the turbinated bodies (lower and middle). In twenty-four hours amelioration of her mental condition is perceptible to her family and friends: restoration to health is quickly accomplished.

Mr. T., age 25 years, has naso-pharyngeal catarrh and aural catarrh, with tinnitus aurium and deafness, acquired irritability of temper, melancholia; partial loss of memory, inability to think any length of time on one subject; has either frontal or occipital headache all the time; has insomnia, agoraphobia and anæsthesia of the skin in spots; has ocular catarrh and asthenopia and neuralgia in different parts of the body. Tuning fork heard best in left ear; drumheads slightly opaque and *without polish. Hearing S. A.,* six inches; D. A., eighteen inches. This is a case of extreme neuræsthesia. Patient has been, on account of the above conditions, tempted to commit suicide, and will not remain *alone night or day*; "says he will kill himself if left alone, and can't help it," is deluded.

Mrs. M. D., age 40 years, has been affected with intra-nasal disease about 15 years; the time dates to an *attack of acute* rhinitis during the influenza, 1872. There was extensive hypertrophy of the lower and middle turbinated process, marked nasal stenosis causing pressure. Symptoms—headache, both occipital and *frontal*; patient seeks solitude, is melancholic, wants to stay at home all the time; *though she* has a lovely home and earthly blessings, her sadness and despondency last; sheds tears without provocation, is not, in feeling and disposition, her former self. Cauterizing the turbinated bodies and other local treatment, with a blood and nerve *tonic*, effect a cure.

Mr. H., age about 40 years; farmer, family history good, general health excellent, excepting the affection in upper air passages. Though he has been a hard worker and able to transact business, his health, for the last year or two, has *been greatly impaired; he feels languid, indifferent, tired,* that he is losing interest in business, has nasal stenosis, is a mouth breather, has an oppressed, full *sensation* in the naso-orbital regions; constant headache, greatly aggravated by colds, sudden changes in weather and hot sun; dislikes to be in company, seeks solitude, is melancholic, irritable, peevish, morose; has an indifferent, stolid, and insane expression; *has constant pains in various regions of the body,* at times increased in severity.

In the spring of 1891, his symptoms for worse were increasing; he sought no professional advice, but tried to work or wear off his indisposition; he went to the field to plow, had a violent headache, stopped plowing for a while and lay down on the ground; from this time has no recollection of what transpired for days. He failed to come home, left horse in the plow. *Family and neighbors institute a search,* but Mr. — could not be found. A nephew was in the city of Lexington and saw Mr. — on the street in his shirt sleeves and old working clothes. Mr. — could give no account of himself, did not know where he was, how or when he came to that city, nor on what business; said he "had a bad headache and lay down in the field," and was aimlessly wandering over the city, speaking to no one, and like the "Wandering Jew," finding no rest but continually passing on, virtually was lost to himself and family and friends and surroundings. His nephew brought him home; he does not sleep well, appetite capricious; is very weak and nervous, says his "head (forehead) and left half of head hurt terrible head, that the left half of head throbs all the time." A rhinoscopic examination reveals a naso-pharyngitis, hypertrophy of the lower and middle turbinated bodies, nasal stenosis; the post nares and vault of pharynx is a purplish red, and swollen, angry appearance, coated with thick, tenacious inspissated mucus; great tumefaction; the left side of the head is *sensitive to touch; the tragus* and mastoid and auditory canal show great pain and anguish on touch, the drumhead is bulging and greatly congested; paracentesis is resorted to; the throbbing pain, abnormal sensations rapidly subside. The naso-pharyngeal chambers are *sprayed* and cleansed with a mild antiseptic wash and daily medicated for a week with mild, soothing astringent non-irritant remedies, the congestion and inflammation reduced to a minimum. Now the turbinates are cocained and *cauterized,* and the nasal stenosis relieved in 72 hours. From the latter treatment, the mental faculties begin to clear up; the clouds gradually pass away; patient is sprayed for three weeks with mild astringent, anti- and aseptic, soothing remedies and in a month is cured of all mental aberr*ation*. The nasal stenosis and enlarged turbinates have been removed and the lining of the naso-pharyngeal chambers placed in a healthy state; patient is restored to former health and has no appearance in manner, expression or acts to what he was before the treatment.

Formerly, it was difficult to get the general profession to attach much importance to diseases of the upper air passages. They consider them local, and not capable of producing constitutional manifestations, and will tell a patient his intra-nasal disease does not amount to much, it will never *kill him; to* take outdoor exercise, eat nutritious *food*, and sleep eight hours out of every twenty-four, and then laugh at patients for having acquired great irritability, melancholia, or tinnitus aurium from having rhino-pharyngitis, and will jocularly remark: You are hysterical, or are malingering. What absurdity! How irrational are these remarks to an intelligent and honest sufferer, whose only desire and prayer are relief and cure. I know no more troublesome affection than naso-pharyngeal and aural disease to the patient. Intra-nasal affection was, a few years ago, considered incurable; but now the light has dawned, and cure after cure is being made, though it will take the profession at large many years yet to realize what is the pathology, etiology, differential diagnosis, prophylaxis, the best therapeutic measures, and the sequels of intra-nasal diseases.

The symptoms characteristic of hypertrophic catarrh are, more or less impairment of the faculties of the will, intellect, emotion, and memory, irritability, anger, nasal obstruction, impaired nasal respiration, oral respiration, and hawking from the posterior nares of the characteristic yellow, ropy muco-pus. When the recumbent posture is resumed, there is a dropping or gravitation of the secretion to the posterior pharyngeal wall, which often causes irritative cough; at morning, when the patient arises, there is a great commotion of the respiratory muscles, produced in trying to rid the naso-pharynx of the abundant tenacious secretion, and nausea and vomiting are often the results. Other results are headache, either frontal, vertical, or occipital, impairment of one or more of the senses of smell, sight, taste, or hearing, hæmoptysis, and epistaxis, impaired articulation, tickling in the throat, constant inclination to swallow, paroxysms of sneezing, insomnia, frightful dreams, suicidal tendency, and inclination to suspect and doubt the sincerity of the truest friendship. The catarrhal inflammation may extend to the larynx and trachea, and give rise to the symptoms of laryngitis and tracheitis. Many catarrhal patients regard the thick, white, yellowish inspissations of muco-pus which are hawked from the naso-pharynx as tubercles expectorated from the lungs, and if a slight hæmorrhage of the throat occurs from the irritative cough and violent rasping of the throat, they think they are the subjects of prodromal phthisis. Even in epistaxis, if the blood gravitates and trickles from the vault and posterior nares into the pharynx, producing cough and irritation of the throat, and is ejected by the mouth, it is supposed to have come from below the glottis, when, if a minute physical examination of the chest, and a rhinoscopic and laryngoscopic examination were made, the site of the hæmorrhage would be located in the vault or posterior nares, and all mental and nervous shock, which are often more prejudicial and enervating than the occurrence of a true pulmonary hæmorrhage, would be avoided. Many victims of catarrh have a vacuous and depressed expression, and are gloomy, absent-minded, easily harassed, so that life seems a burden to them. Cold hands and feet, impaired circulation, numbness, anæsthesia, or hyperæsthesia of one or more parts of the body, peripheral neuralgia, palpitation of the heart, and anorexia, are frequently present in catarrh of the upper air passages.

COMPLICATIONS AND SEQUELS OF CHRONIC CATARRH.

It is very easy to account for the diverse affections following catarrhal inflammation of the upper air passages when the anatomical, pathological, and neurological relations of the parts are considered. The meninges and base of the brain are in close proximity to the catarrhal mucous membrane, and many blood vessels that the latter supply, also supply the former, either directly or indirectly. The same is true in regard to the distribution of the cranial nerves. They communicate with various ganglia and proximate and remote organs, and convey irritation directly or reflexly to different parts of the body. With what facility, then, when irritation or pain is produced in the terminal filaments of the nerves supplying the mucous membrane of the upper air passages, can it be transmitted to distant organs or members or brain! It is equally as easy to have irritation or congestion of the brain follow chronic catarrhal inflammation of the upper air passages. In the nasal cavities are the special nerves of smell, the olfactory nerves connecting the olfactory ganglia with the central parts of the brain, and communicating with the nasal branch of the ophthalmic, the anterior dental branch of the superior maxillary, the spheno-palatine, and the naso-palatine ganglia.

The gustatory, one of the special nerves of taste, is distributed to the tongue, and communicates with the submaxillary ganglion and hypoglossal nerve. The chorda tympani is a nerve of taste, a branch of the facial, and supplies the *mucous membrane* of the *drum*, also communicating with the gustatory. The glosso-pharyngeal arises from the medulla oblongata, and is distributed to the mucous membrane of the base of the tongue, pillars of the *fauces*, *tonsils*, *soft palate*, *middle ear*, *Eustachian tubes*, *drums*, and *upper part of pharynx*. It is a nerve of taste, sensation, and motion. The spheno-palatine ganglion supplies the *tonsils*, *soft palate*, *uvula*, *pharynx*, and *Eustachian tubes*.

The pneumogastric nerve, communicating with other important nerves, as the spinal accessory and the glosso-pharygeal, and with important organs (four vital ones—the heart, lungs, stomach and liver) supply the mucous membranes of these organs and that of the respiratory trail. They also supply the mucous membrane and muscular coat of the œsophagus, and send the superior laryngeal nerves to the mucous membrane of the larynx and crico-thyroid muscle. The inferior laryngeal nerve is a motor nerve, and supplies all the muscles except the crico-thyroid.

The spinal accessory nerve is a motor nerve, arising from the medulla oblongata and spinal cord, but receives sensitive filaments from the pneumogastric. It has external and internal branches, unites with the inferior laryngeal and recurrent branches of the pneumogastric, supplies the cleido-mastoid and trapezius muscles, and gets sensitive branches from the first, second, and third cervical nerves. The internal branches are directly connected with the vocal movement of the larynx; the external with respiration. The hypoglossal arises from the *medulla oblongata*, and is a motor nerve of the tongue, but receives sensitive filaments from other nerves after it leaves the brain.

The facial nerve, arising from the *medulla oblongata*, is a motor nerve to the muscles of the face, to those of the *external* ear and, by its *tympanic* branches, to the *stapedius* and laxator *tympani*, through the otic *ganglion*, the *tensor tympani*, through and by connection of its trunk with the *vidian* by the petrosal, the *levator palati*, the *azygos uvulæ* and a few muscles of the neck, and receives sensitive filaments from the fifth.

The fifth nerve, the great cranial nerve of sensation, is divided into three branches. First is the ophthalmic, which supplies the lachrymal gland sac, conjunctiva and ophthalmic ganglion of the sympathetic and *nasal branch* to *Schneiderian membrane*.

The second division, the superior maxillary, supplies the teeth of the upper jaw and *mucous membrane* of the *antrum maxillare*, and the third division, the inferior maxillary, supplies the external ear and meatus, filaments to anterior two-thirds of tongue, lining of cheek, fauces and lower jaw, integument of chin, lower lip, and lower half of face and muscles of mastication. It is both a sensitive and a motor nerve.

Through the medulla oblongata and spinal cord, irritation of the mucous membrane of the upper air passages is conveyed to the brain, to the arm, forearm and hand by the brachial plexus, to the chest and its contents by the dorsal and sympathetic nerves, to the abdomen and its contents by the lumbar and sympathetic, and to the lower limbs by branches given off from the lower portion of the spinal cord and the sympathetic.

Neuralgia, partial paresis, hyperæsthesia, analgesia of the extremities, epilepsy, chorea, and accompanying chronic naso-pharyngeal catarrh, are readily explained through reflex irritation, and subside when proper treatment is given the catarrh.

The sequels of naso-pharyngeal catarrh are reflex cough, sneezing, stenosis of nasal cavities, ocular catarrh, asthenopia, aural catarrh, headache—either frontal, vertical or occipital—nasal polypi, tonsillitis, enlarged tonsils, hypertrophy of the submaxillary, anterior and posterior cervical glands, patulency of Eustachian tubes, hæmorrhage from the throat—either the naso-pharynx, larynx or trachea—epistaxis, laryngitis, tracheitis, bronchitis, and catarrhal phthisis, neuralgia, or numbness of the limbs or trunk, anæsthesia or hyperæsthesia of the skin, paresis of arm and forearm, dyspepsia, hay fever, irritability, melancholia, partial loss of memory or intellectual faculty, insomnia, frightful dreams, agoraphobia, vertigo, palpitation of the heart, neurasthenia, stammering, suicidal tendency, asthma, chorea, epilepsy, loss of taste, anosmia, anæmia, anorexia, deafness, reflex irritation of the genito-urinary organs, an abundant discharge of nasal mucus or sneezing during coitus, aphonia, erythema and herpes of the nasal integument and lining, tinnitus aurium, otalgia, dysphagia and constipation. In cases of naso-pharyngeal catarrh of long standing there is a tendency to irritation, catarrhal inflammation or debility of all the mucous membranes of the body.

When we consider the pathological elements of the various forms of chronic catarrh, and engrafted upon them, the very frequent or recurrent subacute naso-pharyngitis, with increased dilatation of the blood-vessels, hyperæmia, redness, heat, tumefaction and pain, followed by exudation of liquor sanguinis, diapodesis of the leucocytes, increased infiltration of the connective tissue, cell proliferation and disorganization of lymph; rhinoscopic examination showing a congested, red, dry and swollen appearance of the mucous lining—later on the dryness gives way to moisture and an abundant secretion of mucus or muco-pus, the mucous and submucous tissue is œdematous, infiltrated and thickened, and the glands and follicles are distended and abnormally active; and often added to this, the pressure of a polypus, septal spur, ridge, an exostosis enchondroma, deflected septum and adenoid growth in the vault and fauces, causing irritation and pressure symptoms, congestion, and producing irritation and inflammation by continuity, contiguity and reflex imitation in distant organs and nerves; it is very easy to explain why mental aberration should attend long continued disease of the upper air passages, as well as other sequelæ.

About, or less than, a decade ago, the rhinologist was considered to exist only in name—a myth, and not entitled to a foothold in the profession; but to-day, rhinology has become one of the chief cornerstones of the temple of medicine and surgery. It is built on physiological, histological and pathological rocks; upon these we, the rhinologists, have builded our church. The gates of doubt, charlatanism, ridicule and infidelity shall no longer prevail, and now, in this enlightened day, "*he who doubts is damned already.*" To the general practitioner we say: Give the stomach, liver, heart and alimentary canal and chest organs a rest, and come up higher and see the light turned on, not through a glass darkly, but see new realms, diseases and pathological lesions, for old things have passed away. Behold a new creation!

To the gynecologists and genito-urinary surgeons the rhinologists are ready to say, Through reflexes and neuroses we meet you, not only halfway, but all the way. The intra-nasal tissue is glandular, erectile, and has various nerves, blood and lymph channels ramifying it like the utero-genital organs, and on proper provocation, sends out reflex irritations and congestions to the spinal cord, brain and other remote organs.

To the alienists we say, Look into the naso-pharyngeal chambers, and often a cause for insanity can be found. To the oculist, aurist, dentist: You must bow in reverence to rhinology, for your work is very often *nil* unless you pay your respects to the rhinologist, for often he only can solve your difficulties, and cure your patients. The more frequently you consult him, the better it will be for humanity. To the surgeon we say: You are indispensable.

The successful rhinologist, like the ideal gynecologist, must, from necessity, be a skilful and conservative surgeon.

Rhinology is a haven in which many "mortals" find rest, ease, surcease of sorrow, health, peace, joy and long life.

INFECTIOUS PSEUDO-MEMBRANOUS FOLLICULOUS TONSILLITIS AND PHARYNGITIS.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

BY W. E. CASSELBERRY, M.D.,
OF CHICAGO.
Professor of Therapeutics and of Laryngology and Rhinology in the Medical School of the Northwestern University (Chicago Medical College); Laryngologist to Wesley Hospital.

Repeated confirmation of the discovery of the specific bacillus of true diphtheria has stimulated renewed clinical as well as bacteriological study of other pseudo-membranous inflammations of the tonsils, pharynx and nose, so that our literature of the past few months has contained numerous accounts of "Tonsillitis Lacunaris," "Angina Follicularis," "Pharyngitis Fibrinosa,""Pharyngitis Phlegmonosa," "Rhinitis Membranosa," etc.; a group of diseases which cannot be said to be as yet sufficiently and accurately described, for in some respects they closely resemble diphtheria while in other features they differ widely from that disease.

The opinion of bacteriologists that in these affections diphtheria can only be excluded positively by the absence of the Klebs-Loeffler bacillus, as determined microscopically, is doubtless correct as applied to a few border-line cases, yet one should not permit this fact to engender neglect of macroscopic signs and clinical symptoms upon which a differential diagnosis may also be made, usually with greater promptness, and with reasonable certainty. We are, however, better able to do this now, since we know that in a bacteriological sense, at least concerning diphtheria, there *is* an exact line of demarkation to be drawn.

Concerning the various forms of folliculous tonsillitis and pharyngitis, bacteriology has not yet taught us so much, but we expect to show, from a clinical standpoint, that at least two of these forms of tonsillitis, are as distinct from each other as they are, on the other hand, from true diphtheria.

The recital of an interesting case in point will make our meaning more explicit.

The patient—one of the most intelligent and popular physicians of Chicago, had been exposed to infection by attendance on a case of so-called scarlatina-diphtheria.

A distinct sense of malaise and hebetude with slight soreness of the throat preceded, for a day or two, a chill, which was followed by a temperature of 104° F. Our first examination was made the following morning: temperature 102° F., pulse 100, skin perspiring, face flushed, mental hebetude, and enlargement of the cervical lymphatic glands. The tonsils were only slightly swollen, but were deeply congested and exhibited a thin, whitish, pseudo-membranous punctated deposit which corresponded with the follicular openings. Behind each tonsil, and separated from it by the posterior pillar, the chain of muco-lymphoid glands which occupies the angles of the pharynx on each side and courses thence upward into the naso-pharynx, had developed into a mass larger than the tonsil itself, and was covered by a similar deposit. Two or three isolated muco-lymphoid glands on the posterior pharyngeal wall likewise presented whitish points. No membrane could be observed at any time on any portion of the pharynx other than as described on the purely glandular parts, but we wish especially to emphasize the aspect of this deposit. It was *not* in "cheesy" pellets which often protrude from the crypts through the follicular orifices and which are composed of fat, epithelial debris, inspissated mucus, etc. It was a veritable pseudo-membrane, thin, gray, translucent and firmly attached to the underlying mucosa. Its punctated appearance around the mouth of each follicle suggested that the larger part of the pseudo-membrane might lay *within* the glandular structure—that the crypts and follicles were likewise lined with it. Here and there two, three or four puncta, from close proximity, ran together forming somewhat larger spots, and an occasional layer of muco-pus if not cleaned away would lend an appearance of still greater extent and uniformity to the pseudo-plague. Nevertheless, as far as concerned the pharynx alone, the absolute limitation of the exudate to the muco-lymphoid glandular structures and its punctated appearance differentiated it from the customary picture of genuine diphtheria, the aspect being plainly that which can best be described under the name of septic or infectious tonsillitis and pharyngitis.

But within the nose the view was somewhat different. After shrinkage of the congested turbinate bodies by cocaine spray and dislodgement of an abundant, viscid secretion, one observed a distinctly pseudo-membranous deposit to cover the vestibule and extend within the right nostril as far as one could see, that is especially over the cartilaginous septum narium and anterior part of the inferior turbinate body. This membrane was *uniformly* distributed over all visible parts in the right naris, but otherwise here also it differed from the ideal diphtheritic deposit, even when observed in the nose, it being thinner and semi-translucent. It had more the aspect of deadened epithelial debris, but was evidently not merely such. The left nostril was less affected. The external nasal appendage was much swollen, painful and of decided erysipelatous hue, the redness, however, being confined, not extending above the bridge of the nose. A good post-rhinoscopic view was not obtainable.

In explanation of this nasal feature of the case time permits us only to state, that non-diphtheritic pseudo-membranous rhinitis is common, that a variety of intra-nasal inflammatory states are accompanied by fibrinous exudates in which the absence of the Klebs-Loeffler bacillus has been repeatedly determined. Other microörganisms usually of the streptococcos or the staphylococcus species are often found and it is probable that infection, either primary or secondary by these microbes may result under favorable conditions in the formation of a pseudo-membrane.

I have only to remind rhinologists of the frequency with which an exudate forms after electro-cauterization of the turbinate bodies, and that individuals differ widely in their susceptibility to this formation. In my own experience a pseudo-membranous exudate has followed cauterization much less frequently since I have exercised special care in operating to leave an unbroken eschar, thus serving to prevent secondary infection by microörganisms.

The eyes of our patient were also affected, the right eye very severely, but as stated by Dr. Boerne Bettman, who had charge of these organs, they manifested none other than evidences of severe conjunctivitis.

The patient was confined to the house for two weeks, and suffered from a sense of depression for about two weeks more, when complete recovery ensued without any signs of the diphtheritic sequelæ, paralysis or nephritis. The treatment does not fall within the scope of this paper.

A certain interest attaches to this case by reason of the conjunction of the pseudo-membranous rhinitis with the follicular tonsillitis and pharyngitis, but the pressing question with these two conjoined as with either separately concerns the diagnosis: Is it, or is it not diphtheria? We might regret the absence here of bacteriological investigation, yet such, in part at least, would have defeated the very object of this paper which is to present, in connection with recently acquired knowledge of the bacteriological relationships, such a study of the clinical features that a reasonably certain diagnosis can be made therefrom in the sick room; for I submit that it is there and at once that one needs to answer this question correctly, and that too, in the nature of things most times without the aid of the microscope.

And first, what has bacteriology already taught us as to the identity or non-identity of these processes? It is established that genuine diphtheria is occasioned by the Klebs-Loeffler bacillus. But other microörganisms are capable of exciting pseudo-membranous inflammation of various clinical types which Loeffler is cited as having grouped together under the generic term of pseudo-diphtheria, meaning of course that they are not diphtheritic at all. Clinically they differ from true diphtheria in some one or more particulars—in character of membrane, constitutional symptoms or sequelæ, but resemble it so closely that until the advent of bacteriological support, we were often unable to state positively that these non-diphtheritic pseudo membranous cases might not be diphtheria of a mild type. This was often true of folliculous tonsillitis and pharyngitis or "angina follicularis." Investigators have uniformly failed to find the Klebs-Loeffler bacillus in this disease, but have found a variety of other microbes.

Sendtner,[1] of Munich, studied four cases and found the streptococcus pyogenes and streptococcus erysipelatosus, and recalls in this connection the clinical relationship which has been observed between erysipelas and puerperal fever, and angina follicularis. Barnabei,[2] of Rome, observed twelve cases which he denominated "primary erysipelatous angina." They were characterized by redness and swelling of the tonsils and fauces, and from the crypts of the tonsils an exudate soon showed itself in the form of small white points. A microbe, indistinguishable from the streptococcus erysipelatosus, was present in all cases. Dubler (*Virchow's Archives*, Heft. 3, 1891) also reports two cases of infectious phlegmonous pharyngitis in which both in the pus and in the splenic blood a microbe indistinguishable from the streptococcus of erysipelas, was found.

Rendu,[3] reports two cases in which virulent pneumococci were found, in which the angina follicularis was contracted while sleeping among pneumonia patients.

Hajek,[4] of Vienna, describes four cases of non-diphtheritic "pharyngitis fibrinosa"[4] connected either with the staphylococcus pyogenes aureus or the streptococcus pyogenes, one of which cases supervened upon "tonsillitis lacunaris."

It scarcely suffices, however, to attribute these diseases exclusively to the organisms named, since with the exception, perhaps, of the streptococcus erysipelatosus, they are all found in the mouth in health,[5] but in at least some of the cases, it is stated that they were present in unusually large numbers, and that the cultures showed great virulence.

With our patient the infection was with reasonable certainty traceable to a case of "scarlatina-diphtheria," but from a bacteriological standpoint this disease is likewise a false diphtheria, occasioned by microbes other than the Klebs-Loeffler bacillus. Bourges,[6] of Paris, classifies the anginas of scarlet fever into: 1. Angina erythematosa; 2. Angina pseudo-membranacea, occurring early or late in the disease, circumscribed or diffuse, mild or severe; 3. Angina gangrenosa. He concludes from bacteriological investigation that the erythematous and nearly all the early pseudo-membranous forms as well as many of the late pseudo-membranous cases, are caused by secondary infection with the streptococcus pyogenes which happens usually through the tonsils. Huebner,[6] of Leipzig, Babes,[7] of Pest, and Seifert,[8] of Wurzburg, assert practically the same. This is not assuming, however, that in exceptional instances secondary infection by the Klebs-Loeffler bacillus might not occur and genuine diphtheria become associated with scarlatina, but the probabilities favor the position that the case by which our patient was infected, was an ordinary streptococcus pseudo-membranous angina.

We have designated our case as "infectious," by which is meant that some distinct species of parasitic organism, having gained access to the affected parts, has there multiplied and acted, both directly and by elaboration of chemical poisons, as the specific cause of the disease. The contagious nature of certain forms of tonsillitis has long been suspected and much evidence thereof has been published by individual observers,[9] yet the fact has not been generally credited, for the reason that the greater number of cases failed of any such signs, and when evidence of contagiousness was conclusively present the disease would be attributed to the diphtheritic infection or the subject be dismissed as a mere coincidence. We now know that the diphtheritic infection, *i. e.*, the Klebs-Loeffler bacillus, is not present in this disease, but that there are present in the form which we describe under the name of infectious pseudo-membranous tonsillitis, other microörganisms of kinds that establish for it a possible contagious character.

I am sure that clinically, one can distinguish at least, *two* types of acute folliculous tonsillitis and I propose to name them in contradistinction to each other: 1. Simple folliculous tonsilitis, and 2, infectious pseudo-membranous tonsillitis.

With the simple form there may or may not have been previous chronic hypertrophy or inflammation; it is conditioned, if not caused by "taking cold," *i.c.*, by refrigeration of some part of the body surface, which determines vascular engorgement of the tonsils exactly as in another individual it may occasion vascular engorgement of the nasal turbinated bodies. The tonsil swells, the follicular openings are obliterated and the pent up secretion acts as a further irritant. it becomes inspissated and mixed with epithelial débris; it is soon forced out to the surface of the gland in the form of "cheesy" pellets, which are altogether different from a pseudo-membrane. Finally, when the tonsils are free of this accumulated débris, or at times, earlier, if the globules are forcibly dislodged and removed, the tonsillitis rapidly subsides.

The *infectious pseudo-membranous form* we have just described at length in relating our case, and it will again be referred to in the summary.

Now, we note in current literature a disposition to attribute all cases of tonsillitis and pharyngitis to "infection," the truth of which we cannot deny, for pathogenic microörganisms, being everywhere and especially present in the mouth, might readily invade the tonsils at a time when their power of resistance is lessened by vascular engorgement and pent-up secretion, and may even play an important part in the formation of the "cheesy" globules. In simple folliculous tonsillitis, however, such infection would seem more like a secondary than a primary process, for in typical cases the inflammation subsides as soon as the tonsil can be freed of its accumulated inspissated secretion; but "infection," either primary or secondary, affords a ready explanation of cases which deviate from the typical, which are mixed, and in which both "cheesy" and true punctated pseudo-membranous exudate can be discerned.

In summarizing, we will state what are seemingly the logical conclusions of this study:

That we can distinguish at least two forms of acute folliculous tonsillitis.

1. Simple folliculous tonsillitis, which is characterized by congestion and swelling of the tonsils, with protrusion from the narrowed follicular openings of cheesy globules which may simulate a punctated pseudo-membranous exudate, but which is really not such; without evidence of primary parasitic infection as a cause, and therefore not contagious; capable, however, of being transposed into a conglomerate variety of tonsillitis by secondary infection with pathogenic microörganisms; usually not preceded by a distinct chill, and not accompanied by much fever or systemic depression.

2 Infectious pseudo-membranous tonsillitis, which is characterized by deep congestion, but often only by moderate swelling of the tonsils, and by a punctated exudate of pseudo-membrane, the spots of which are in size from 2 to 4 mm. in diameter, and are attached around the follicular openings, presenting the appearance as if the crypts were also lined by the same material; *unlike* the cheesy pellet the exudate is thin, translucent, and so intimately connected to the underlying mucosa that it cannot be detached without bleeding or without force; two or more puncta may join at their borders and form larger spots, but after cleansing away all muco-purulent matter this punctated conformation of even the larger pseudo-membranous areas may be readily discovered. In addition to the tonsils, any or all of the muco-lymphoid glands in the pharynx may be likewise affected, especially the chain of glands located just behind the tonsil and separated from it by the posterior pillar, but the pseudo-membranous exudate is limited absolutely to the glandular structures of the pharynx, although careful cleansing and critical inspection will be required to demonstrate this fact. The cause is infection by any one of several species of pathogenic microörganisms, *e.g.*, streptococcus erysipelatosus, staphylococcus pyogenes aureus, pneumococcus,, streptococcus pyogenes, etc., and it is not unlikely that with closer clinical study aided by bacteriological confirmation, we may be able in the future to further subdivide this form of tonsillitis into varieties in accordance with the particular species of microörganism which has acted as the cause. It is infectious or contagious and is known to become endemic. It is often ushered in by a chill, and accompanied by moderate or even high fever. It may be complicated by albuminuria, but is not followed by paralysis. The Klebs-Loeffler bacillus of true diphtheria is never found in this disease. That by attention to these details this form of tonsillitis and pharyngitis, with very few exceptions, may be readily distinguished clinically from true diphtheria, which is characterized not by a thin translucent, punctated exudate, but by thickish, opaque, diffuse plaques of pseudo-membrane which are not limited to the glandular structure, but which, when originating on the tonsil, rapidly embrace as well the pillars of the fauces, and extend to or involve at the same time the posterior pharyngeal wall and velum palati.

NOTE: Since the completion of this paper our attention has been called to an article by Dr. Adolph Baguinsky, in the *Berliner Klinische Wochenschrift* of February 29, 1892. He examined for bacilli 154 cases, being all that were admitted as diphtheria to the *Kaiser und Kaiserin Friedrich Krankenhaus* during a certain period. They all exhibited "the same naked-eye local changes, *i. e.*, a dirty gray-white to green pseudo-membrane on the mucosa or tonsils." He does not state whether or not cases were included which are ordinarily denominated tonsillitis, and characterized by a *punctated* pseudo-membrane limited to the glandular structures, but one would infer that such were not included among his cases. Of the 154 cases, Klebs–Loeffler bacilli were found in 118, and these were the severe cases. The others contained only cocci and ran a mild course.

Baguinsky concludes that there are two diseases called diptheria—exhibiting the typical diphtheritic deposit, which can only be distinguished from each other microscopically; a result which is interesting, but not especially pertinent to the subject of our paper, which is tonsillitis. Baguinsky mentions also two cases of "rhinitis fibrinosa" unaccompanied by serious systemic symptoms in which Klebs–Loeffler bacilli were found, and advises caution regarding a non-diphtheritic diagnosis in this disease. The two cases, however, indicate but little, for it is not contended otherwise than that diphtheria, either nasal or pharyngeal, can occur with but slight systemic disturbance.

Closing the discussion, Dr. Casselberry said: I prefaced my paper by stating that "the opinion of bacteriologists that in these affections diphtheria can only be excluded *positively* by the absence of the Klebs–Loeffler bacillus, as determined microscopically, is doubtless correct as applied to a few border line cases." But I have described at length the clinical aspects of these forms of tonsillitis, because I believe it both necessary and possible thus to make a correct diagnosis in the majority of cases. I have been unable to find any record of the presence of Klebs–Loeffler bacilli in cases of apparent tonsillitis in which the pseudo-membrane was of the character which I have described in connection with the infectious form of this disease, *i. e.*, punctated, thin, translucent, and limited to the tonsils and muco-lymphoid glands of the pharynx. The cases cited by Dr. Wright as recorded by Baguinsky and others were nasal cases, evidently nasal diphtheria in which, by reason of the absence of constitutional symptoms, the disease, without microscopic examination, would have been mistaken for non-diphtheritic "rhinitis fibrinosa." As intimated in the paper, it seems to me more difficult to exclude diphtheria in nasal than in pharyngeal cases, although it would seem preposterous to assume even a possible diphtheritic infection as a cause of the many pseudo-membranous deposits which occur after the use of the electro-cautery in the treatment of hypertrophy of the turbinate bodies.

AT the late meeting of the Virginia State Medical Society, Dr. Landon B. Edwards, the efficient secretary of the society and editor of the *Virginia Medical Monthly*, was unanimously elected an Honorary Fellow of that organization.

THE WARREN TRIENNIAL PRIZE of $500 has been awarded by the staff of the Massachusetts General Hospital to John Strahan, Belfast, Ireland. Subject "Ricketts."

THE EDISON PHONOGRAPH AND THE BETTINI MICRO-PHONOGRAPH.

THE PRINCIPLES UNDERLYING THEM AND THE FULFILMENT OF THEIR EXPECTATIONS.

Read in the Section of Laryngology and Otology, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit. Mich., June, 1892.

BY J. MOUNT BLEYER, M.D.,
OF NEW YORK CITY.
SURGEON TO THE NEW YORK NOSE AND THROAT INFIRMARY, EDITOR ELECTRICAL REVIEW, NEW YORK CITY.

Gentlemen: I intend to lead you into the mystery of mysteries, by the demonstrations I am about to make and explain to you, regarding the adoption of the Edison phonograph and the Bettini micro-phonograph as an aid to our and other sciences. It will be necessary for me to make some explanatory remarks in order that you more fully comprehend the real mechanism of these wonderful contrivances of the age, both from a physical and mechanical point. I will then follow up by illustrating to you clinical phonograms, and other records and will then take before you several such records so as to demonstrate the practicability of my investigations.

The value of these two machines cannot be overestimated at the present time of my experimentations, and here I wish to state, that even some of my crude methods of taking and reproducing records or phonograms are not as yet sufficiently developed to make them thoroughly practicable for many reasons, but suffice it to say, that those which will be demonstrated to you, at this period of my investigation must at once lead all thoughtful students to think of the further prospects of the growth and development in the mechanism as well as in the application of the phonograph and the micro-phonograph. The results nevertheless are at this date gratifying and from my practical illustrations to you, I wish each of you to judge for himself.

At the onset of my lecture, I must say: That as a means of quantitative analysis, in reference to sound, musical and other tones can be measured by the phonograph and the Bettini micro-phonograph as heat is measured by the thermometer and air pressure by the barometer. The aim of all sciences is to become more and more quantitative, because you can have no standard of measure. When, however, the standard of measure can be obtained the analysis is quantitative and scientific, and the use of these two machines in physiological researches is a thoroughly scientific matter.

It is found that each succeeding age has either given birth to new scientific facts, or has elaborated preëxisting ones.

The phonograph was suggested to Mr. Edison in the spring of 1877, while making some experiments with a machine for automatically recording and reproducing Morse characters. This apparatus indented the characters in paper, much the same as a Morse register, The reproduction was accomplished by this new invention, which was intended to receive telegraphic messages from one circuit and to transmit them upon another without the aid of a skilled operator, and also to facilitate business in a repeating office.

As a source of amusement and to test the rate of speed at which a Morse operator could receive or read, the reproducing machine was caused to run at a high velocity, and when the speed was increased to such an extent that the ear could not recognize the Morse characters, Mr. Edison noticed that the machine gave off a humming or musical sound, which varied according to the characters on the record, apparently talking in a language which was not understood.
